During the following autumn and winter the frequency of all three bacterial groups rose to a high level. The numbers of indol-forming strains of hæmophilic bacilli commenced to rise in October, increased gradually until the following February, and rapidly during March, reaching a peak coincidently with the peak of the influenza epidemic, which visited Manchester in the spring of 1927. Thereafter the frequency of this bacterial group declined, at first steeply, then more slowly, remaining at a relatively high level after the epidemic had subsided. The frequency of hæmophilic bacilli, as a whole, showed a fluctuation very similar to that of the indol-forming sub-group, save that the rise commenced later, in December, 1926, and then proceeded steeply to a synchronous peak in March, 1927. The general form of the frequency curve of hæmophilic bacilli, as a group, did not, however, differ significantly from one winter to another, whereas the curve described by the indol-forming sub-group during the winter 1926–27 differed sharply from that described during the winter 1925–26.

The pneumococcal carrier-rate, which had remained at a low level between November, 1925, and October, 1926, rose sharply during the latter month to a level higher than any previously encountered. After a slight fall in December it rose to a higher peak in January, at the time when the influenzal epidemic commenced, and then declined slowly, with minor fluctuations, until the close of the inquiry in the following September. Whether this association of events was purely fortuitous, or was in any way significant, it is impossible to say. A far longer experience would be needed to establish the existence of a correlation between any variation in the nasopharyngeal flora, and fluctuations in the prevalence of a particular respiratory infection. We would suggest, however, that similar surveys, carried out in several localities and over considerable periods of time, would probably yield a definite answer to the question at issue, and that such an answer is worth obtaining.

(2) Although the frequency of hæmolytic streptococci in the nasopharynx varied over a considerable range during the period July, 1925–September, 1927, these variations showed no clear association with any recorded epidemiological events.

(3) The frequency of saccharose-fermenting, Gram-negative cocci was high throughout the whole period of inquiry. The results do not suggest that this group of bacteria is in any way related to the prevalence of respiratory disease.

(4) No evidence was obtained that pneumococci, hæmophilic bacilli, or hæmolytic streptococci are concerned in the causation of the "common cold," using that term in its widest sense, and not confining it to cases of acute suppurative nasal catarrh.

(5) The four bacterial groups studied in this inquiry occur far less frequently in the nose than in the nasopharynx. Their frequency in the latter situation does not differ sensibly from their frequency on the tonsils. Pneumococci and hæmophilic bacilli were isolated less frequently from mouth-washings than from nasopharyngeal swabs; in the case of hæmolytic streptococci and saccharose-fermenting Gram-negative cocci, the two methods of examination give essentially similar results.

MEDICINE AND THE LAW.

The Evans Cancer Treatment Case: a Question of Costs.

THE Court of Appeal has overruled the decision of Mr. Justice Charles upon one aspect of Mrs. Burrell's claim against Mr. Evans, an unqualified medical practitioner, described in THE LANCET of May 31st p. 1189. Mrs. Burrell's cause of action, it may be remembered, was framed in three different ways. First, she contended that the defendant had made fraudulent representations by which she was induced to enter into the contract for treatment by the so-called Evans cancer cure. Secondly, she said the defendant warranted to cure her permanently and in three months, and broke his warranty. Thirdly she said he was negligent in his treatment of her. Every plaintiff, of course, must show in formal fashion, in a statement of claim or otherwise, the specific legal ground of his or her action and the remedy asked for. These three causes of action legally distinct, were naturally not readily distinguishable when the evidence was being offered on the whole of the case, and when the jury was trying to make up their mind on the merits and facts and on the trustworthiness of the witnesses. In the upshot the jury, after an absence of nearly three hours, failed to agree on the first and third branches of the claim —namely, the questions of fraudulent misrepresentation and of negligence; they did, however, definitely find in favour of Mr. Evans on the second matter— namely, the allegation that he had warranted to cure Mrs. Burrell in three months. Counsel for Mr. Evans, rightly claiming that he had at any rate succeeded on the issue of contract (as distinct from the issues of fraud and negligence), asked for his costs on that issue. Mr. Justice Charles refused the application on the ground that the case was tried as a

whole, that there was an intermingling of allegations and evidence, and that it would be inconvenient to give judgment on one point only if the action were to be tried again. The Court of Appeal has now said that this was wrong. Lord Justice Scrutton points out that it is not a mere matter of costs. If and when the case is set down for a new trial, the question will arise whether the plaintiff can again put forward her claim on the alleged warranty, and the defendant will then be entitled to say that the decision of the jury at the previous trial has closed that avenue. The question of the costs of this appeal was referred back to the judge who tried the case, with liberty to apply.

The disentangling of the costs of defending one part of a case from the costs of defending other parts is one of the mysteries which are solved without publicity in the taxing department of the law courts. In this particular case the problem of apportionment will be as intricate as usual. It it were a mere rule-of-thumb practice that a party, having succeeded on one out of three separate issues, was entitled to one-third of his total costs, it would be easy enough. Here, if it can be said that all three issues (and the evidence thereon) were inextricably intermingled, success on one issue alone will carry with it a larger proportion of the cost of the services of solicitors, the instructing and briefing of counsel, and the attendance of witnesses.

A Motor-car Insurance Claim.

The medical profession, which perhaps, more than any other, relies on the use of the motor-car, will note with interest a recent case on a motor-car insurance policy. The plaintiff's car caused injuries to a third person; the insurance company repudiated liability because the car was not "the insured car" covered by the policy, but a new car with which the plaintiff had replaced the original vehicle. Having had occasion to have the hood of the "insured car" repaired, the owner decided to buy a new car in view of the heavy cost of repair. He therefore handed over his old Lancia, paid £100, and became owner of a new Lancia. A telephone message was sent to his brokers to transfer the insurance to the new car, but unfortunately they did not carry out the instruction. The policy covered the liability of the motorist in respect of the use of "any motor-car (other than a hired car) provided that such car is at the time of the accident being used instead of the insured car." The judge had to decide whether the new car, purchased in the circumstances already mentioned, was being used "instead of the insured car" within the meaning of the policy. Mr. Justice Roche said there was no express or implied term in the policy that continuance of the ownership of the car originally insured was necessary. If the original car was burnt and the owner bought or borrowed another in its place, he would be covered if he could properly be said to be using the substituted car "instead of" the old one. The judge seems to have been influenced by the fact that the plaintiff bought a car of the same type as the original "insured car"; he refrained from deciding the position if the plaintiff had used a car of an entirely different type, "if, for instance, the insured car had been a baby Austin and he had used a Rolls-Royce." Doctors should keep an eye on the terms of their policies in this kind of matter. It is particularly important that the owner should be covered against risk of damage to a car or to third parties either where he has changed his type of car or where he is using a substituted car temporarily. If he should deem it advisable also to cover himself against liability for the expense of hiring a car when the insured car is under repair, he must see that this special provision is included.

Spiritualism and Testamentary Capacity.

In recent litigation over the will of the late Dr. Abraham Wallace, the court obviously shrank from the question whether, or to what extent, a strong interest and belief in spiritualism and psychic phenomena could amount to a delusion such as makes a person unfit to execute a will. Dr. Wallace died at Paignton last January at a ripe age, leaving an estate of about £10,000. There had been two wills, one of December, 1928, the other of November, 1929. The executrix, Mrs. Perkins, propounded the later will under which, subject to various small legacies, the deceased bequeathed to her the residue of his estate, expressing his gratitude for her care during his declining years. His children resisted this will, and also the will of 1928 under which Mrs. Perkins merely received a legacy. They contended that neither will was duly executed, that Dr. Wallace was not at the time of sound disposing mind. He had, they said, been interested for many years in spiritualism; after 1926 he became so obsessed that he suffered from delusions, and after his wife's death in November, 1928, his mind became so unbalanced that he was not fit to make a will. In the formal language of probate pleadings, the defendants put Mrs. Perkins to proof of the righteousness of the transaction; they claimed that Dr. Wallace died intestate, and they asked for letters of administration. The evidence was directed to two different points. First, there was the elementary question whether the wills were properly executed. Two domestic servants, who had signed their names as witnesses of the 1929 will, said that they had not seen Dr. Wallace himself sign the document. The second and bigger question was that of the testamentary capacity of the deceased. On behalf of Mrs. Perkins, several witnesses said that he was a strong-minded and capable man, whose mental power appeared in no way warped or twisted by his spiritualistic beliefs to the detriment of sound judgment. This opinion was supported by extracts from his correspondence on business and family matters. On the other hand, there was evidence that he believed himself in communication with his dead wife, who appeared to him at séances and indicated to him particular courses of conduct. Sir Oliver Lodge was in court on the third day of the trial but was not called as a witness, the case being settled on the intervention of Lord Merrivale. The President, after seeing counsel in his private room, pronounced against the execution of the 1929 will, expressing doubts whether any tribunal could have been satisfied that the testator affixed his signature in the presence of the two attesting witnesses, or that he acknowledged it in their presence. Lord Merrivale then pronounced in favour of the 1928 will, declaring it to have been duly executed by a competent testator who was aware of its contents and of the position of his affairs. All allegations made on both sides had been withdrawn by agreement, and a situation of some difficulty was thus ended. The President, in conclusion, remarked that this left Dr. Wallace untouched in the judgment of those who had great affection for him, his own family, his friends and confidants, "and, indeed, those who were his fellow-believers in occult matters about which it would not be proper that I should say anything further." Thus the main issue, inevitably raised in the circumstances of this particular case, remained undecided. Apart from any element of undue influence, the courts would hardly be prepared to say that no believer in the occult can make a

valid will. Evidence of insanity creates a presumption against testamentary competence, but it is always permitted to reply that the testator's delusions or insanity were irrelevant to the scope of the will, or insufficient to destroy or suspend testamentary capacity. Even where the presumption of insanity is supported by the fact of confinement in an asylum, it may be rebutted by satisfactory evidence that the will was executed during a lucid interval.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

HOSPITAL SUNDAY FUND AND SWEEPSTAKES.

Following on the threat to the Dublin Hospital Sunday Fund made by the Archbishop of Dublin (see THE LANCET, July 5th, p. 45) a meeting of the supporters of the Fund, held recently, decided to refuse grants to any hospital which took part in promoting, or received any benefit from, a sweepstake. In proposing the resolution, the chairman of the fund, the Earl of Meath, put forward no arguments for its adoption other than the attitude taken by the Archbishop and certain other supporters.

Having quoted the opinions expressed by the Archbishop, Lord Meath said that "the Hospital Sunday Fund had to decide whether they should fall in with the Archbishop's views or give up the Hospital Sunday Fund altogether." The proposal was opposed, though unsuccessfully, by Senator Sir Edward Coey Bigger. The situation created by the decision of the Hospital Sunday Fund is unfortunate. The decision gives no help to the solution of the financial problem of the Dublin hospitals; it merely asks the public to transfer their subscriptions from certain hospitals to certain others, and to be guided in their choice, not by the needs of a particular hospital or the value of the work it performs, but by special ethical views on gambling. Correspondents of the daily press have not failed to point out that the clerical upholders of the Sunday Fund are enforcing on the hospitals a more rigid ethical code than they think it necessary to apply in regard to the maintenance of their own churches.

WOMEN DOCTORS FOR INSURED WOMEN.

At a recent meeting of the Belfast Trades Council the Secretary read a letter from the Ministry of Labour of Northern Ireland, replying to the Council's request for the appointment of women doctors for insured women. The Minister pointed out that the Council were asking him to depart from the British practice. If he were to accept the view that women claimants should be examined only by doctors of their own sex it would mean duplicating most of the appointments of full-time or part-time medical officers throughout Northern Ireland, and consequently an increase in the administrative cost of the health insurance scheme. Any examination which was carried out by a referee was undertaken only to the degree necessary to enable a correct opinion to be formed as to the claimant's capacity for work. He should also like to inform the Council that on every occasion on which a woman was examined a nurse was present.

PAYING PATIENTS AT LEAMINGTON.—The coming centenary of the Warneford Hospital, Leamington, is to be marked by the erection of wards for private patients. The income limits have been fixed as follows:—Single persons, under £350 a year; married couples without children under 16, £450; widows and widowers with a child or children under 16, £450; married couples with a child or children under 16, £550. The medical fees are not to exceed 20 guineas.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

AN OFFICIAL REPORT ON THE LÜBECK DISASTER.

THE Minister of the Interior has published a report on the investigation made by his department in Lübeck. The report states that the Lübeck authorities had not informed the German Health Office before introducing the Calmette method of inoculation with B C G; it was their duty to do so, because in 1927 the Health Office had recommended some reserve in using this method. Moreover, after subcultures had been made from the original Calmette culture, it would have been their duty to ascertain that these were innocuous to animals before distributing them for use on infants. The supervision of the infants was also insufficient. The report states that Prof. Deycke is to be blamed because he had destroyed a great part of the subcultures, so that an examination was very difficult. After the virulence of the material used on infants was discovered at the autopsy on an infant who died during the treatment on April 26th, doses of B C G were still left in the hands of midwives and administered to infants. The Lübeck authorities were informed much too late by the doctors concerned, and the Central Government not before May 14th. The number of deaths has now increased to 52; some of the infants whose condition had improved have become worse again, and all the infants who have received cultures will be in danger for many years.

OPERATIONS WITH HIGH-FREQUENCY CURRENTS.

Prof. Heymann, chief surgeon of the Augusta Hospital in Berlin, lately read a paper before the Berlin Medical Society on operations with high-frequency currents. He said that the tissue may be cut in the same manner as with an ordinary sharp scalpel. Hæmorrhage is very slight, the blood from the small vessels being coagulated under the influence of the heat, whilst bleeding from larger vessels may be arrested by introducing the current into the artery forceps. The cut tissues remain dry because they are covered by a stratum of coagulated albumin, this being also a protection against infection. The method has been applied by Prof. Heymann in laparotomies, in growths of the brain, amputations of the mamma and of the extremities, and especially in furuncles and carbuncles. The great advantage is the arrest of hæmorrhage without ligatures; the drawbacks are the fact that the surgeon is dependent on the proper working of the diathermy apparatus, the muscular contractions caused by the currents, and the possibility of explosions produced by the proximity of ether and other anæsthetics. The difference between the action of diathermy and thermocautery is that the coagulation caused by diathermy is very superficial, not exceeding 2 mm. in depth. The idea that wounds produced by diathermy heal less rapidly than wounds madeby a scalpel is erroneous. In the course of the discussion Prof. Heymann's views were generally confirmed. The method was considered to be especially valuable for cosmetic operations.

INTERNATIONAL HYGIENIC EXHIBITION.

In 1911 an international exhibition of hygiene was held in Dresden, and many of the exhibits were preserved to form a permanent museum. This museum has now been organised and was opened this summer, together with a great international exhibition, under the patronage of the German and foreign governments. The German government

presents an historical exhibition of the development of hygiene and of medicine in the past 100 years. The German cities show models of sewage fields, slaughter houses, public baths, market halls, methods of food control, and people's kitchens. There are also on view model clinics for mothers and infants, and for tuberculous, venereal, and alcoholic patients. A special department is devoted to superstition and quackery, where the advertisements are compared with their alleged results. This department is amusingly and cleverly arranged, and since it evidently attracts the public it provides valuable propaganda against quackery. Other departments are concerned with gymnastics, industrial hygiene, hygiene of dwellings, food, and clothes. A big hall is devoted to the modern hospital. There are models of operation theatres, sick rooms, hospital wards, isolation wards, hospital dispensaries, and laboratories. Another part of the exhibition is devoted to the hygiene of infants, where the measures used in the attempt to decrease infant mortality are demonstrated. Special exhibits illustrate the combat against tuberculosis and against cancer. Of the foreign government exhibits that of Russia is the largest. It is designed to show the great progress of hygiene since the institution of the Soviet system. The other governments have exhibited diagrams and statistical tables concerning hygiene in their respective countries. The nucleus of the exhibition is the permanent museum, and its aim is to popularise hygiene not by dull lectures and statistical records, but by vivid illustrations. The exhibition will be open until November and is well worth visiting.

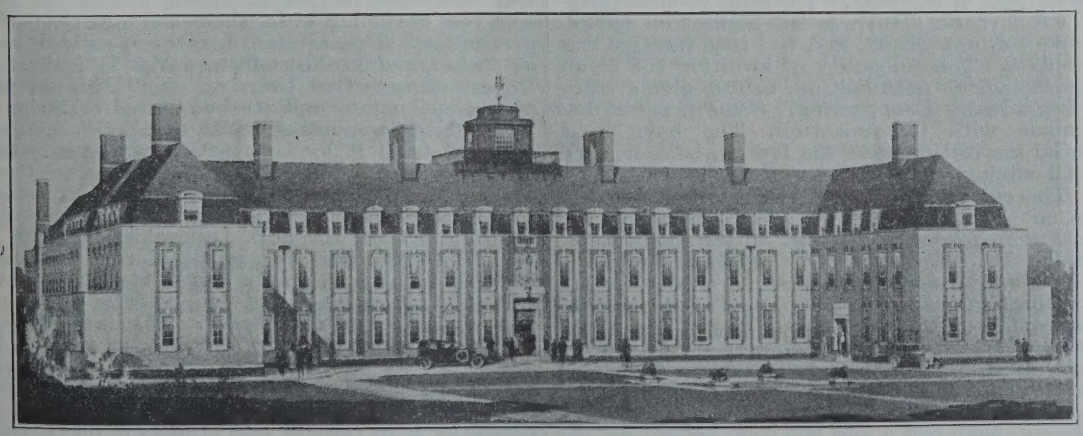
EXPERIMENT ON PATIENTS.

The German Health Council, a representative body connected with the Health Office, composed both of doctors and laymen, has been deliberating on experiments on patients. The Council holds that such experiments are necessary for medical progress, but must be made in accordance with medical ethics. Experiments which might as well be done on animals, and experiments on moribund patients without the intention of saving life, are to be avoided. Powerful new remedies should not be used for human beings until tested on animals, and then only by agreement with the patient. Experiment in hospitals should only be made by the chief doctor or under his personal control. In medical publications the respect due to the person of the patient must never be neglected, and the responsibility of medical men in this regard must be explained to medical students.

MARGATE AND DISTRICT GENERAL HOSPITAL.

THE work of the old Cottage Hospital at Margate has been transferred to a new building in St. Peter's-road, and the hospital was officially opened by Prince and Princess Arthur of Connaught on July 3rd. The new institution, which is to be run by the same staff as the old, is placed on a fine open site facing St. Peter's-road. On the left of the entrance hall are the offices and on the right the X ray department. The latter department was placed here in order to be equally convenient for in-patients and out-patients and also to allow room for expansion. All the wards and the theatre have been fitted with plugs so that patients can have treatment with X rays in bed. The radiological machinery is in a room beneath the filming room, so that no noise is heard in the latter. In the north-west wing is the out-patients' department with consulting, surgery, and ophthalmic rooms and a theatre. The wards are on the south side, away from the road and facing a country view. There is accommodation for 14 paying patients in wards containing one, two, or three beds. On the first floor there are two large surgical wards, two maternity rooms with vita-glass windows, and a children's ward with eight cots. Staff rooms are in the centre of the building and nurses' and maids' bedrooms, bathrooms, and lavatories on the third floor. The operating suite is on the first floor of the north-west wing. The hospital is heated by coke-fed boilers in the basement; these can be converted for oil-burning at a small cost if desired. The apparatus is a low-pressure hot water system and there is a minimum of unsightly drop-piping. The building is distinguished by a turret, from which a fine view of the surrounding country and sea is obtained. Precautions have been taken against breakdowns in the various supplies; gas stoves and gas lamps have been installed, and the beamless electric light in the theatre can be supplied with current from storage batteries. Every bed has a window facing south, or nearly south, its own electric light overhead, and a reading lamp on the locker.

The building and equipment cost £70,000; a sum of £57,000 has been subscribed, and a further £5000 was handed to the Prince in purses at the opening ceremony. The hospital thus needs another £8000 to be cleared of debt. The architects are Messrs. Adams, Holden and Pearson of London, and the general contractors Messrs. Reg. Elliott and Co., Ltd., of Margate.



The New Margate Hospital.

PUBLIC HEALTH SERVICES

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are 1929 statistics of eight districts of differing local government status and in various parts of the country.

Name of district and estimated (R.-G.) mid-year population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Infant and neonatal mortality.	Young child (1–5yr.) mortality.	Maternal mortality from childbirth.
Cambridge B. (60,730)	11·8	12·3	0·87	1·73	2·6	1·7	47/35	14	4·2
Barry U.D. and Port (39,010)	17·5	11·0	1·00	1·61	1·4	1·6	70/39	38	5·8
Darwen B. .. (37,780)	12·9	14·7	0·55	1·72	3·4	2·5	86/49	—	8·2
Spenborough U.D. .. (30,780)	14·3	14·6	0·58	1·36	3·1	3·3	79/25	47	4·5
Ramsgate B. (31,440)	17·4	13·7*	0·80	2·20	2·1	1·8	75/35	22	9·1
Weston-super-Mare U.D. (27,620)	8·6	13·5	0·61	2·17	1·6	2·6	71/42†	—	0·0
Taunton B. (24,860)	15·9	12·7	0·84	1·45	2·0	2·4	52/30	12	7·5
Hereford R.D. (13,060)	15·5	13·9	0·92	1·68	2·1	2·9	104/49	—	5·0

Stillbirths per 100 live births: Cambridge (notified), 4·3, Barry 4·8, Darwen 5·7, Spenborough 4·7, Ramsgate 2·9, Weston-super-Mare 3·8, Taunton 3·0.

* Standardised 11·4. † Death during first week only.

Cambridge.

Dr. Andrew J. Laird points out that owing to the rise in the death-rate and the fall in the birth-rate, there was in 1929 for the first time no natural increase in the population of Cambridge. The increased death-rate was mainly of older people during the exceptionally severe weather of the first quarter and attributed to influenza, diseases of the heart, and bronchitis. Cambridge did not, however, suffer from influenza in 1929 so badly as many other places. The deaths numbered 38, which may be compared with 56 in 1927, 40 in 1922, 127 in 1918, and 33 in 1919. The infant mortality was exceptionally low after the first month. Thus out of 34 infant deaths, 25 occurred in the first four weeks, and only nine during the rest of the year. The number of notifications of diphtheria (240) was the highest on record. The type was not severe, and the case fatality was 4·1 per cent. The old policy of awaiting the result of bacteriological examination before giving antitoxin is gradually disappearing. Some progress has been made with immunisation. The boys in a residential institution were the first to be done, and a special clinic was opened towards the end of the year. The only case of small-pox was a stewardess on the s.s. *Tuscania*. She had a mild attack, the contacts were revaccinated, and no secondary cases occurred. Dr. Laird estimates that from 400 to 500 more houses are needed. The health committee has been authorised to build 70 to meet the needs of certain families—viz., those from houses for which a closing order has been made; those from houses requiring substantial repairs; and those with large families who are unable to pay the rent of a municipal house. Thirty of these houses have been erected, and are occupied, and a site has been bought for the remaining 40. The Cambridge Housing Society has also built a third group of houses (making a total of 61) for the accommodation of large families.

Caravan dwellings are on the increase, and it is suggested that Cambridge may have to adopt the Birmingham scheme of setting aside parking places provided with all necessary requirements.

Barry.

Dr. Percy W. Kent says the chief occupation of the inhabitants is at the docks in connexion with the export of coal. The continued slump in trade has led to prolonged unemployment and an increase in casual labour, but so far the health of the community has not been affected. The municipal hospital is at present only used for accidents and surgical cases. The question of its extension has been under consideration for some years. Medical, children's, and maternity wards are needed, and also accommodation for massage and electrical treatment. During 1929 the Barry Chamber of Trade gave £1000 for the purchase of a new X ray apparatus. The water-supply of the district has been unsatisfactory for several years but it is hoped that the new supply from Taff Fechan will be available during 1930. The problem of inadequate housing still exists, and there is overcrowding in several parts of the district. Dr. Kent points out that local authorities select the best tenants although they are in a better position than private owners to supervise undesirable tenants. He regrets that the suggestion of the sanitary inspector some years ago that a certain part of the housing estate should be set aside for such tenants was not acted upon. Until some such experiment is tried the problem of the undesirable tenant will not be solved. Dr. Kent also points out that the charges for subtenancies should be controlled. Several tenants receive more rent from subtenants than they themselves pay for the whole house. Efforts are made to encourage clean milk production, but some of the producers do not coöperate. During the year one cowkeeper was fined for failing to keep the flanks and udders of his cows clean.

The work of the port sanitary service has been greatly altered during recent years by deratisation. The inspection of vessels of from 2000 to 5000 tons and the estimation of the rat population takes a sanitary inspector and a rat-catcher from two to three hours, and the fumigation occupies another three hours. There were about two black rats to three brown rats amongst those destroyed on ships during 1929.

Darwen.

Dr. James Robertson says the water is mainly a soft moorland supply. The water in the reservoirs is treated with sodium carbonate before sand filtration and lime-stone is placed in the bed of the brook. Analysis of the tap water shows only gr. 1/300 of lead per gallon. The rainfall for the year was about 57 inches, and in November nearly 11 inches. Dr. Robertson says that the river should be covered in at various points and its bed paved. During the year a large amount of refuse and debris had to be removed from it by corporation workmen. Owing to the lack of small and low-rented houses there is some overcrowding, mainly from the occupation of houses by more than one family. The joint town planning scheme for N.E. Lancashire has just been completed, and it is now proposed that the area be divided into two groups with statutory powers. Out of 90 observations the time-limit for black smoke was exceeded in six instances. The limit allowed is five minutes per hour for one, two, or three boilers and seven for four or more. Owing to the unprecedented depression in the cotton trade a number of mills have been permanently closed, several have been closed for long periods, and others are on part-time. This has resulted in a very great diminution in the

town's consumption of coal and may have to some extent accounted for the increase in the sunshine registered. Thus the record for 1929 was 1409·8 hours as compared with a 20-years' average of 1146·4 hours. There is no local maternity home or children's hospital, but the poor-law infirmary situated in Blackburn admits maternity and other cases from Darwen. This hospital also has an orthopædic unit.

Spenborough.

Dr. L. Pickering-Pick reports that the deaths were 44 more than the average for the previous five years. One peculiarity of the returns was the large excess of female deaths—viz., 273 out of 451. The deaths under one year were 50 per cent. greater, and those from 1 to 25 years exactly double those in 1928. The increased mortality from respiratory diseases affected the two extremes of life. The infant mortality-rate of Spenborough was ten higher than the rate for the 157 smaller towns, but the neonatal deaths were five fewer than in the previous year. There is no maternity hospital in the district, but the municipal hospital of Bradford and the Heckmondwike and Batley maternity homes receive Spenborough women on payment. The isolation hospital arrangements are unusual—Spenborough was formed by the amalgamation of Cleckheaton, Liversedge, and Gomersal, and the cases from each of these three districts still go to different hospitals. There is no general hospital in the district, and the hospitals at Bradford, Dewsbury, Batley, and Leeds are utilised. There were 82 cases of small-pox with no deaths. The cases constituted two small epidemics.

Dr. Hilda A. Channon (part-time) conducts an antenatal clinic. In 1928, 93 cases made 251 attendances, and in 1929, 111 cases made 325 attendances. The mothers attend well on the whole, she says, and are beginning to introduce their friends, but the standard of general physique among the pregnant women of the district is depressingly low. Free dental treatment has been provided, but only a few can be persuaded to avail themselves of it, and several motners state that their dentist has refused to extract teeth on learning that they were pregnant.

Ramsgate.

Dr. W. J. Bannister states that the remaining 20 of the 360 houses on the council's Whitehall estate have been completed, but that there is still a demand for the non-parlour house at a low rental. Through the generosity of Dame J. Stancombe-Wills a maternity ward of eight beds, costing about £10,000, is being added to the general hospital. Dr. Bannister has advocated the institution of an open-air school for some years, and says there are many children who would benefit greatly therefrom. As the borough will not face the cost, he suggests that provision be made for open-air education for special classes of children throughout the year in connexion with the proposed new centrally situated school. This appears to be an opportunity for the "Derbyshire" type of school. The council's station for the sterilisation of cockles from Pegwell Bay has been discontinued, and those engaged in the trade have been notified that they must provide their own means of sterilisation to the approval of the medical officer of health. The hours of sunshine were 1897·8, and the inches of rainfall 18·79.

Weston-super-Mare.

Dr. A. E. Remmett Weaver, who was appointed on the resignation of Dr. John Wallace, also performs duties for the county council's school medical service. In commenting on the increased infant mortality, he attributes this to an exceptional number of accidents at birth. Of the 17 deaths of infants, ten occurred from a few hours to a week after birth, and in four instances inquests were necessary.

For years the isolation hospital has been regarded as inadequate. At a conference with the county council it was decided that Weston must either build a new hospital, enlarge the present one, or join a combination scheme. Accordingly a scheme has been approved for the addition to the present hospital of a 12-bed scarlet fever pavilion, a 10-bed observation block, an administrative block, and a new laundry and mortuary. The maternity and child welfare work is mainly organised by a voluntary association. There are no maternity beds in the district, but when the extension of the general hospital was planned, a ladies' committee raised £6500 for the provision of maternity wards. The old X ray department has been converted into maternity wards, which have not yet been opened, as no funds are available for administration and maintenance. Excellent water has been available from a spring in the limestone at Banwell since 1924. The water is pumped to a tower on Worlebury Hill and another lower level reservoir. The village of Banwell is to have a piped water-supply and a drainage scheme contemporaneously. As these schemes may threaten the purity of the spring, Weston's water-supply is being chlorinated. In the eastern part of the district, the only direction in which Weston can expand, there is an ancient system of land drainage by rhynes. Complaints of flooding have arisen owing to the inability of the rhynes to carry off surface water during heavy rains. An endeavour is being made to adjust this matter. The council erected 20 houses during the year. The hours of bright sunshine were 1790·5, as compared with an average of 1455·3 for the past ten years. The heaviest fall for one "rainfall day" was 2·99 inches on August 3rd.

Taunton.

Dr. John Allen reports that the water had to be cut off from 6 P.M. to 7 A.M. from April 29th onwards, and that it was not found possible to resume a continuous supply until Dec. 10th, after the heavy rainfall. A plant for treating the water with chlorine was installed in February. The rainfall on the watershed during 1929 was 41·6 inches, but 27·7 inches fell during the last quarter. Steps are being taken to increase the present sources of water-supply.

During September and October a special survey was made of all the houses in the town which were without through ventilation. The survey gave a total of 771 houses of this type, with rents varying from 2*s.* 6*d.* to 6*s.* a week. Most of these houses are arranged in courts. There is no inside sink or water-supply, only a tap and gully in the court. Coal and refuse are stored in a space under the stairs, and there is no ventilated food store. Sixty-six of the houses are classed as much below the condition of the remainder on account of marked lack of light and air, serious dampness, infestation by vermin or dilapidation. The shortage of houses prevents closing orders from being made, and many of the tenants cannot pay more than 6*s.* a week. At the time of the survey only 12 of these houses were unoccupied. The total houses in the borough in 1921 were 5376, so that about one in seven is of the type mentioned in the survey. Amongst other needs mentioned by Dr. Allen are a proper dustbin for each house, better drinking water facilities in the schools, and less primitive methods of retailing milk.

Hereford.

Dr. R. Wood-Power's district includes 39 parishes completely surrounding the city of Hereford, and has an area of 65,669 acres. In most of the parishes, shallow wells or springs provide the water-supply, and most of the "dip" wells are not protected, as they might be, from surface pollution. Dr. Wood-Power regrets that more advantage is not taken of the city's supply in all the parishes surrounding it. There were 21 notifications of diphtheria in nine parishes. Ten of the cases occurred in one house under unsatisfactory home conditions. This large family has now been provided with a "council" house. The council has formulated a scheme for

assisting owners under the Housing (Rural Workers) Act, 1926, but no applications were received during 1929. Some 2500 hop-pickers came from outside the county, chiefly from South Wales and Staffordshire, to 22 farms in the district. As few as six went to one farm, and as many as 700 to another. Much greater regard for the welfare of the pickers is shown than formerly. Some farms have canteens, and fresh meat and fish are obtained by the periodical visits of tradesmen.

MENTAL HOSPITAL REPORTS.

THE 116th annual report of the GLASGOW ROYAL ASYLUM records that there were 536 patients in hospital at the end of 1929, 155 of them being private cases. There were 21 more voluntary than certified cases among the 156 admissions. The recovery-rate was 34·5 per cent. and the death-rate 8·9 per cent. The medical superintendent pleads for the establishment of a psychiatric institute similar to that of New York. The asylum is soon likely to have a new charter to enable it to change its name to one more consonant with modern ideas. Wireless has now been installed throughout the hospital and has been a great boon. The occupational therapist submits a special report showing the success achieved in her department. The dental surgeon reports the total of 252 attendances and 244 extractions under local anæsthesia. There is a full consulting staff, but as yet no means of treatment by hydro- and electro-therapy.

The KINGSEAT MENTAL HOSPITAL at ABERDEEN had 701 certified patients on the register at the end of last year, and 15 voluntary cases were admitted during the year. No less than 11 of the admissions were suffering from general paralysis and all were too feeble for malarial treatment. Some improvement was obtained in two cases from graduated injections of sodium nucleate. Aberdeen has done little for its mental defectives, and 12 adult cases were admitted to the mental hospital during 1929. Despite these difficulties, the institution showed a recovery-rate of 31·4 per cent. and a death-rate of only 8·8 per cent. The question of the appointment of a dentist is under consideration, and the visiting commissioner urges the advisability of occupational therapy on a wide scale. The medical superintendent pleads for some way of keeping the senile case out of the general ward, possibly in a bungalow type of hospital. A veranda and solarium have been added to the Maudsley Parole Villa. Many patients work on the farm and take a keen interest in it. Four of the staff obtained their R.M.P.A. certificates during the year.

The MONMOUTHSHIRE MENTAL HOSPITAL at ABERGAVENNY had 1244 patients on the register at the end of last year. The recovery-rate was 27·5 per cent. and the death-rate 6·5 per cent. There was an outbreak of typhoid in the spring, and after prolonged efforts a chronic carrier was isolated in March, but there seems to be another undetected, as two more cases occurred in December. A small X ray apparatus has been installed. The visiting surgeon has been called in twice and has operated once, and the dental surgeon has visited weekly. Full parole has been allowed to 46 men, while 78 men and 25 women have had liberty within the estate. During the year eight nurses passed the final examination for the nursing certificate.

The COUNTY AND CITY OF WORCESTER MENTAL HOSPITAL at POWICK had 1047 patients in the hospital at the end of last year. The recovery-rate was 38·7 per cent. and the death-rate 5·6 per cent.; post-mortem examinations were made in 71·7 per cent. of the fatal cases. The general health was good, but there was one case of scarlet fever. The dentist examines all patients on admission and supplies treatment when necessary. The committee are considering the installation of electricity and the reorganisation of the sewage disposal. Six men have had parole beyond the estate and 33 men and 8 women within the grounds; two patients were allowed out on trial and two wards are administered on the open-door principle. The visiting commissioners wish that these privileges could be more widely extended. Five male and three female nurses obtained their R.M.P.A. certificates during the year.

The CHESHIRE COUNTY MENTAL HOSPITAL at PARKSIDE had 1303 patients on the register at the end of the year, and there has been a certain amount of overcrowding on the male side; this has been met by transferring 18 men to workhouses. The recovery-rate was 28·7 per cent. and the death-rate 7·47 per cent. The general health was satisfactory, apart from a severe epidemic of influenza in the spring. Of the 13 cases of general paralysis admitted, six were suitable for malarial treatment, with the result that three were discharged and one was considerably improved. Light treatment was given to 33 patients for mental illness and to 116 for physical reasons; 55 patients were treated with radiant heat, baths, sprays, and massage. The report is illustrated with photographs of a hammock fitted with a vita-glass canopy and of the hydrotherapy treatment rooms. In the occupational therapy department 76 women and 27 men are occupied in various handicrafts, while 52 men and 32 women were introduced to various games. A new room is to be added to this department shortly. The laboratory has undertaken the examination of specimens for the Macclesfield Town Council. The report includes notes by members of the staff on the treatment of varix by injection of quinine and urethane and the relation of the cause of death to the type of insanity. It is well known that cases of dementia præcox are particularly liable to tuberculosis; it was found that five out of 68 schizophrenics and 41 out of 67 melancholics died of heart disease and chronic nephritis. The paranoid and cycloid types predominate in the list of deaths from malignant growths, while the epileptic imbeciles succumb most easily to colitis and pneumonia. There is also a report from the laboratory showing that 1911 routine investigations were made and that a small outbreak of dysentery in June and four sporadic cases of typhoid caused a good deal of work. The Lange colloidal gold test has given consistently satisfactory results. Eight nurses and one attendant obtained the R.M.P.A. certificate, bringing the total to 48 nurses and 27 attendants.

The 101st report of THE LAWN, LINCOLN, omits the usual historical introduction, as this institution is now well known. The year's work shows a further increase in the number of admissions, these being 43 on an average number resident of 65, and for the first time the voluntary boarders outnumbered the certified patients (24 to 19). Of the certified cases the majority would have been suitable for admission under the new temporary treatment order proposed in the Mental Treatment Bill. The recovery-rate was 35·29 per cent.; it was 42·85 per cent. for females but none of the male admissions were recoverable cases. The general health was good, and there was no epidemic disease. A class in folk-dancing has proved a great success, especially for patients who lack spontaneous activity. Handicrafts of various kinds have been taken up during the year, and it is hoped before long to employ a full-time occupations officer. The new veranda attached to the admission and convalescent ward has enabled quiet borderline and convalescent cases to be treated separately in the open air under glass permeable to ultra-violet rays. The financial situation of this excellent institution is unfortunately constituting a serious problem, and very few patients can be received at rates less than the cost of £4 4s. per week. The visiting commissioner urges the governors to consider making a wide appeal for funds, as it would be a calamity if the amount of relief they afford had to be reduced. The hospital has no endowment and receives practically no support from voluntary contributions. It is to be hoped that Lincolnshire will soon realise the importance of early treatment in the only hospital in the county which

can receive voluntary boarders, and supply the financial help which will enable its charitable work to be extended.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED JULY 19TH, 1930.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 126 (last week 138); scarlet fever, 1817; diphtheria, 1221; enteric fever, 108; pneumonia, 563; puerperal fever, 35; puerperal pyrexia, 100; cerebro-spinal fever, 11; acute poliomyelitis, 13; acute polio-encephalitis, 4; encephalitis lethargica, 18; dysentery, 6; ophthalmia neonatorum, 120. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on July 22nd–23rd was as follows: Small-pox, 241 under treatment, 3 under observation; scarlet fever, 1762; diphtheria, 1991; enteric fever, 33; measles, 284; whooping-cough, 77; puerperal fever, 24 (plus 14 babies); encephalitis lethargica, 121; "other diseases," 18. At St. Margaret's Hospital there were 18 babies (plus 9 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there were no deaths from small-pox or enteric fever, 16 (1) from measles, 5 (2) from scarlet fever, 22 (2) from whooping-cough, 32 (9) from diphtheria, 39 (9) from diarrhœa and enteritis under two years, and 18 (2) from influenza. The figures in parentheses are those for London itself.

Six deaths from diphtheria were reported from Liverpool and four of the fatal cases of diarrhœa were at Manchester.

The number of stillbirths notified during the week was 327 (corresponding to a rate of 47 per 1000 births), including 57 in London.

OBITUARY

ALFRED BERTRAM SOLTAU, C.M.G., M.D., F.R.C.P. Lond., F.R.C.S. Eng.,

HON. PHYSICIAN TO H.M. THE KING.

WE regret to announce the death of Dr. Alfred Soltau, of Plymouth, which occurred on Saturday last, July 26th, in a London nursing home, at the age of 55.

Alfred Bertram Soltau was born in 1876, the eldest son of George Soltau, a nonconformist minister, who was for a time governor of Dr. Barnardo's Home, and then took charge of a mission church in Tasmania. The son received his early education in Tasmania, and returned to England for his medical training. He entered the school of the London Hospital, where he obtained a scholarship and where afterwards he obtained prizes and distinctions in many subjects, as well as being Anderson Scholar in Clinical Medicine. In the intermediate and final examination for the M.B. London he obtained first-class honours, and graduated in 1900, taking the diplomas of the Conjoint Board in the same year. In 1902 he proceeded to the M.D. and obtained the F.R.C.S. Eng. Deciding to practise in the country he returned to Plymouth, where his family had been well known for several generations; he was appointed honorary physician to the Devon and Cornwall Ear and Throat Hospital and later to the South Devon and East Cornwall Hospital, and was rapidly recognised as a leading practitioner in the district. He became president of the Plymouth Medical Society and of the St. John Ambulance Association for the area, and also of the local division of the B.M.A. He was a prominent citizen as well as a leading practitioner, for he took a keen interest in politics, being president of the Plymouth Conservative and Unionist Association at the meeting in the city of the National Unionist Conference, while his civic activities included membership of the Plymouth Borough Council (1919–25) and chairmanship of the Public Health Committee. These various duties would appear to have given enough work for a medical consultant, but Soltau added to them a practical participation in military medicine. He was one of those who apprehended that a great war would come, and believed in the need for the country to prepare for it. In 1905 he took a Commission in the Devon Volunteer Brigade Bearer Company, and he raised and became the first commanding officer of the 2nd Wessex Field Ambulance (T.F.).

In 1914 the war brought him to the fore. He had the honour and joy of going out to France in command of his ambulance. Both the ambulance and the commanding officer were tested severely, and survived with credit. Soltau's services were recognised by promotion in 1916 to the post of consulting physician to the First and Second Armies, which carried with it the rank of Colonel, A.M.S. He was one of the first consultant officers to be appointed from amongst those who had served in the forward area, and he was familiar with the plight of the various medical units, and able to view their needs and difficulties with sympathy. He realised that a consulting physician and consulting surgeon in the field has vast opportunities beyond the obvious duty of seeing and treating difficult cases, inasmuch as one of the most important functions of the medical service is to maintain the Army in health, and to return to duty as quickly as possible those soldiers suffering from minor maladies. In the difficult days of the autumn of 1917, when the fighting round Passchendaele was dying down, Soltau was consulting physician to an army which contained over half a million men, and in recognition of his activities, and especially because of work done for the gassed, he was appointed in 1918 consulting physician to the War Office and the Ministry of Pensions for gassed cases. He was mentioned in despatches four times; awarded the C.M.G., in 1916, C.B.E., 1919, the Croix de Guerre (France) in 1918, and created Commendador D'Ordre d'Aviz (Portugal) in 1919. In 1924 he was appointed honorary physician to His Majesty the King; A.D.M.S. 43rd (Wessex) Division in 1922, and in 1927 honorary colonel, R.A.M.C., 43rd Wessex Division (T.F.). He was a clinician and interested in all things medical, and not a writer, but his publications include the Section on Gas Warfare in the Official Medical History of the War, and he was joint author of the Ministry of Pensions' Notes on Certain Diseases of the War. In 1919 he took the M.R.C.P. Lond., and was elected to the Fellowship in 1925.

In 1903 he married Edith Mary, eldest daughter of W. E. Watts, of Plymouth, by whom he had one son, George Richard Bertram, serving in the West Yorkshire Regiment, and one daughter. Dr. Soltau died after a long illness on July 26th, and was buried at Hendon Park Cemetery, Mill Hill, on July 30th.

JOHN STEVENS, M.D., F.R.C.P. Edin.

Dr. John Stevens, who died at Edinburgh on July 23rd, was one of the best known practitioners of the city. He graduated at Edinburgh with first-class honours in 1884, and received the gold medal for his M.D. thesis three years later. He became resident physician at the Royal Infirmary, and was admitted a Fellow of the Royal College of Physicians in 1894. He was early associated with the Edinburgh Medical Guild, of which he was honorary secretary and treasurer, and he held strong opinions on the status of practitioners. His interest in these matters led him into active work for the Edinburgh branch of the British Medical Association, and he became a member of the Scottish Committee and a representative on the Council of the Association. Tenacious but considerate in argument, he carried much weight among his colleagues, and his earnest enthusiasm gained their respect. His presence will be much missed at the deliberations of the Council and of the Representative Body of the B.M.A.

THOMAS OUTTERSON WOOD, M.D. Durh., F.R.C.P. & S. Edin., M.R.C.P. Lond.

Dr. Outterson Wood, whose death was announced in THE LANCET last week at the advanced age of 88, died at Torquay, where he had lived for some years after retirement from practice.

Thomas Outterson Wood was born at East Rainton, Durham, in 1843, the son of a father with the same name. He received his early education at Houghton-le-Spring, and entered the Newcastle School of Medicine as one of the first students. He finished his medical education at St. Bartholomew's Hospital, and qualified in 1868 as M.R.C.S. He returned to Newcastle as house surgeon to the infirmary, but an opening having occurred for a resident at a private asylum nearby, he resolved to practice in the special branch of psychiatry which already had attraction for him. In course of time he became physician-superintendent to the Dunston Lodge Asylum, where his first appointment had been obtained, and while there he took the F.R.C.S. and the M.D. Durh., acquiring later the M.R.C.P. Lond., and being elected F.R.C.P. Edin. While at Dunston Lodge he was appointed lecturer in mental diseases and examiner in medical jurisprudence at Durham University, but a few years later he moved to Barming Heath, to take the post of assistant medical officer at the Kent asylum. Then he was appointed by the Commissioners in Lunacy to be medical superintendent at the Isle of Man asylum, which post he held until he started consulting practice in London.

His wide experience soon secured an appointment for him at the West End Hospital for Diseases of the Nervous System, as well as at the St. George's and St. James's Dispensary, while he also served on the Boards of Management of the Fenstanton private mental hospital, and at Bailbrook House, Bath. In 1905 he was elected President of the Medico-Psychological Association of Great Britain and Ireland, a due recognition of many years of able and accomplished work, in several sides of which he was an acknowledged authority. He showed this also in his writings, though they were not numerous. He was the author of the article on the "Law and Practice of Lunacy" in Allbutt and Rolleston's System of Medicine, and of the article in Tuke's Dictionary of Psychological Medicine on "Lunacy Law," and he arranged for the use of medical practitioners a résumé of the Lunacy Act of 1889, which was a distinctly serviceable production. Dr. Wood retired from practice 15 years ago, when he elected consulting physician to the West End Hospital and the St. George's and St. James's Dispensary. To his learning and experience he added, as factors in his professional success, the qualities of kindness and sympathy, with the advantage of a fine presence.

He married 60 years ago Caroline Augusta Charlotte, daughter of Mr. Edward Potter, of Cramlington House, Northumberland, who predeceased him and there was no issue.

HUGH MILLER, M.B. Glasg.

BY the death of Dr. Hugh Miller on July 22nd at the age of 54, the Health Department for Scotland has lost a valuable officer. He was appointed by the late Scottish Board of Health as one of the district medical officers under the National Health Insurance Act and he controlled the Dundee district. Such work demands professional skill, experience of practice and aptitude for administration. Dr. Miller had all three. After graduating at Glasgow in 1899, he held a large number of local hospital appointments and studied in Berlin. His work as a general practitioner was done in Gloucestershire and at Hamilton, in Lanarkshire. During the war he held a captain's commission in the Royal Army Medical Corps and for a time was medical officer in charge of the Prisoners of War Hospital at Sidi Bishi. Afterwards he returned to Hamilton and became honorary secretary of the Hamilton local medical and panel committee and deputy chairman of the Scottish committee of the British Medical Association. Appointment as district medical officer followed, and in this capacity his tact and courtesy were happily combined with a high sense of professional duty. His influence was widely felt.

ALTON CRIPPLES' HOSPITAL.—On Founders' Day at Lord Mayor Treloar's Cripples' Hospital and College at Alton it was stated that the 355 beds are constantly in use, that at the college 50 boys are always in training, and that steady development has been made in orthopædic cases, though the majority of the children suffer from tuberculous disease of the bones and joints. Rebuilding, which will cost £100,000, has become imperative; half of this sum has yet to be obtained.

BIRMINGHAM HOSPITAL CENTRE.—The members of the Birmingham Hospital Saturday Fund, an integral part of the contributory scheme, have agreed to pay a levy of an extra penny a week for five years to hasten the completion of the new hospital centre. This five years' levy is estimated to produce over £350,000, and the scheme was strongly supported by the Lord Mayor on the ground that more than 1000 patients are waiting for admission to the two greater Birmingham hospitals.

DONATIONS AND BEQUESTS.—Mrs. Anne Charlotte Harrison, of Watford, who left £205,340, after considerable private bequests, left half of the residue of her estate equally between Watford District Hospital, the Hospital for Sick Children, Great Ormond-street, London, W.C., and the Royal Blind Pension Society of the United Kingdom.—Miss Louisa Susannah Tucker, of Seaton, Devon, among other bequests left £1500 to the Royal Devon and Exeter Hospital, £500 each to the West of England Eye Infirmary, the Sidmouth Cottage Hospital, the Axminster Cottage Hospital, and the Royal Midland Home for Incurables, Leamington; £200 each to the West of England Institution for the Instruction and Employment of the Blind, the National Institute for the Blind, and the Hospital for Sick Children, Great Ormond-street; and £100 each to the Devon and Exeter Dispensary for Sick Animals, the Royal Society for the Prevention of Cruelty to Animals, the Imperial Cancer Research Fund, Dr. Barnado's Homes, and St. Dunstan's Hostel for Blinded Sailors and Soldiers.

CORRESPONDENCE

THE TREATMENT OF PULMONARY TUBERCULOSIS IN SWITZERLAND.

To the Editor of THE LANCET.

SIR,—May I reply to some of the many surprising and misleading statements that appeared in an article "Reflections on the Treatment of Pulmonary Tuberculosis in Switzerland and at Home" by Dr. W. R. E. Harrison in THE LANCET of July 19th.

That Dr. Harrison has been peculiarly unhappy in his experience of Alpine resorts is regrettable, but that he should have published general conclusions from such limited experience is unfortunate. How many of the Swiss sanatoria Dr. Harrison has visited I do not know, but it is clear from his remarks regarding the average hours of sunshine, the number of hours that have to be spent indoors, the coldness of the ice rinks, the ratio of the sporting to the "curing" population, the shut-in character of the country, the impossibility of finding interesting and level walking, the deplorable monotony of the views and by many other remarks, that he would have done better before having embarked on such dogmatic generalisations to have visited a plateau such as is to be found at Montana.

Dr. Harrison confines his generalisations to Swiss sanatoria in Switzerland, but my experience in Montana for the past three years in a British institution have led me to different conclusions.

In Montana during six winter months the *average* hours of sunshine per day according to Sir Leonard Hill were 5·28, which figure is appreciably greater than that of any other "curing" station in Switzerland (Maurer and Billviller in "Das Klima der Schweiz" give as corresponding figures 4·08 for Arosa, 3·83 for Davos, and 3·63 for Leysin), and which greatly exceeds the 2·85 hours for Falmouth and 2·56 for Margate, given by Sir Leonard Hill. Montana is too sunny to rank among the first-class winter sports places and in consequence the great majority of its visitors are patients and their relatives or friends. Dr. Harrison's remark that "the interest and 'life' of these towns is almost entirely bound up with winter sports and the pleasures associated with hotel life" and that they are therefore unsuitable for "curing" does not apply in the case of Montana.

Although he acknowledges the "invigorating effect" of "the dry and sunny climate" and "the improved appearance" of people who have returned from a holiday in Switzerland, he would appear to minimise the importance of the same stimulus on patients. There is no doubt also that sunshine makes a much more pleasurable business of that valuable therapeutic agent, "air bathing." Sir Leonard Hill has supported many clinical observers by proving that the cool dry Alpine air has a very favourable effect on metabolism. (Much of his research was done at Montana.) The Alpine climate also permits of better conditions for "sun bathing" which, carefully supervised, can be used with safety and to the patient's advantage in a certain number of cases of pulmonary tuberculosis. Further, during the greater part of the winter both my "bed" and "up" cases spend as much as from seven to ten (not "five") hours a day outside and then return to rooms which, contrary to Dr. Harrison's experience, are freely ventilated, both day and night.

Since Montana is situate on an extensive plateau with a panoramic view stretching from the distant mountains above the Simplon in the East to Mont Blanc in the South-West, Dr. Harrison's description of the patient in Switzerland living "in a narrow valley" with "jagged mountain peaks crowding all round," likewise does not apply to this resort.

Under the heading "Occupation and Outlook," Dr. Harrison states that all the Swiss sanatoria are inferior to the English ones in their capacity to provide "cheerful health-giving interests," and he attributes this "defect" to "their being situated in the Alpine towns which cater for holiday-makers." Montana, however, as I have pointed out, is primarily a health resort. Both the scenery and the facilities for "outdoor nature study" compare favourably with England, and the climatic conditions are in every way suitable for patients to watch the skating and other sports.

Dr. Harrison tells us that "in Switzerland the prescribed daily exercise is limited to walking," which later he describes as a "dreary tramp." Now exercise in Switzerland must obviously vary according to the season. Walking, of course, is common to all seasons, and as in England is the most important form of exercise, but in winter a few selected cases are allowed to skate. In summer there are excursions in the country, putting, and fishing for those who are considered fit for such diversions. For indoor recreation there are bridge, chess, billiards, clock-golf, and other pastimes suited to the particular and individual need of the patient.

In the paragraph "Spring and Summer," Dr. Harrison makes the statement that "in June the weather may resemble an English February"—in reply to which I will merely point out that the official figure for the *average* daily sunshine for June of this year (by no means a record one) was 8·1 hours.

In conclusion, I feel that the truth regarding the therapeutic value of the Alpine climate lies somewhere between the extreme anti-Swiss feelings of Dr. Harrison on the one hand, and those of the super-Swiss enthusiasts on the other.

I am, Sir, yours faithfully,

HILARY ROCHE, M.D., M.R.C.P., T.D.D.,
Medical Superintendent of Montana Hall, the new British Sanatorium, Montana, Switzerland.

July 22nd, 1930.

To the Editor of THE LANCET.

SIR,—Dr. Harrison's reflections ought to be read by every general practitioner in the British Islands. I enclose the letter of a former assistant who has had a wide experience of home and Swiss sanatoria, and quote from it:—

> "I quite agree with the article by Harrison . . . but I think I could put it a bit stronger. He talks about the monotony of looking at the same patch of snow from a balcony, but what about the people who have to look at the same patch of wall adorned by a mournful picture with a few words of German underneath? When the sun is shining you won't be allowed to have the window open on 'medical' grounds, the real reason being that the sun would fade the floorcloth. When the sun is not shining you won't be allowed to have the window open for fear the water would freeze and burst the pipes, and you are paying 4 guineas a week for the fresh air treatment!"

The above throws a bright sidelight on this Swiss industry. I think it was a strong sense of duty that caused Dr. Harrison to write what amounts to a

summary of what patients and friends have told me for many years. The severe winters are bracing for the strong, but highly dangerous to the weak. There is an absence of home comforts, home interests, home employment. It is difficult often to exercise in the open because of hills and snow, and graded exercise and work are specially difficult to arrange. It must be admitted that our own climate is superior to that of Switzerland in most respects. Dr. Harrison's final sentence is worthy of quotation: "It is a reproach to medical men that so many of these unfortunates should be allowed to die in a foreign land."

I am, Sir, yours faithfully,

R. S. McCLELLAND.

Llwynwern, Dowlais, July 28th, 1930.

THE USUAL VICTIM.

To the Editor of THE LANCET.

SIR,—It has recently been impressed on me that the gentle art of bilking the doctor can be applied with such finesse as to extort a reluctant admiration even from the victim.

Most practitioners of a few years' standing have discovered that among the growing army of the hard-up, the doctor is recognised as the person whose bills can safely be paid last, and who is the easiest to bilk—he is the usual victim. I was not aware until recently, however, how far the latter process can be carried out with the aid of expert backing from the law.

Last summer I undertook the care for a month of a colleague's case while he went on holiday. The patient's family insisted on specialist supervision, and the fees were agreed upon. After a respectable interval I sent in my bill, and as no notice was taken, repeated the process on several occasions. My last two communications were returned marked by the postal authorities "Gone away."

After a period for meditation I placed the matter in the hands of my solicitors. They were informed by the opposing solicitors that trade was in a very bad state, and that their clients could not possibly pay the amount (although they had been able to reside for the season in an expensive part of London). Encouraging my solicitors to persevere, they were successful in obtaining £10 on account. There was a lull after this for a time, and then hostilities recommenced on a grand scale by the taking out of a writ in the High Court of Justice by my solicitors for payment of the balance. The enemy countered by paying into Court the amount of the debt *less one-third* of the original total. That was a polite intimation that they challenged the amount of the fees. I was then left with the alternative of accepting the reduced amount or proving my case in Court—that the fees were reasonable, &c., which would have required the appearance of medical witnesses to speak of my standing, professional ability, and so on.

The technique was described by my solicitors' clerk as a "dirty trick," but is evidently quite legitimate in the eyes of the law. I may mention, in conclusion, that my colleague's bill was considerably larger than mine, and as he is a Fellow of the Royal College of Physicians, his chances of recovering his fees are somewhat tenuous. We may depend upon it that such experts in the gentle art are aware of the College's prohibition.

I am, Sir, yours faithfully,

FREDERICK DILLON, M.D.

Wimpole-street, W., July 22nd, 1930.

HYPOGLYCÆMIA AND SUPRARENAL TUMOUR.

To the Editor of THE LANCET.

SIR,—Your annotation on this subject (July 26th, p. 200) prompts me to say that quite recently I saw a case of Addison's disease with cerebral seizures remarkably like those due to overdosage with insulin, which I attributed to hypoglycæmia. I then came across a paper by G. Maranon (*Presse Méd.*, 1929, xxxvii, 1021), recording a low blood-sugar in 71 per cent. of his cases of Addison's disease, in which acidosis was also frequent. Cerebral seizures occurred in a number of the cases. He, too, attributes a large part, but not the whole of this to hypoglycæmia. It is interesting in view of the failure of intravenous injections of glucose to benefit the case described in your annotation, that Maranon found this procedure positively dangerous, producing a febrile reaction with serious collapse, and even death. Glucose by the mouth in doses of 25 g., three or four times a day, on the other hand, was distinctly helpful. The reason for this difference is not clear, but it is important to bear it in mind in the treatment of the hypoglycæmia of Addison's disease.

I might add, as you mention the occurrence of hypoglycæmia in necrosis of the liver, that Maranon has shown the existence of hepatic insufficiency in Addison's disease, and that I have seen striking improvement follow the administration of liver extract in this condition.

I am, Sir, yours faithfully,

W. LANGDON BROWN.

Cavendish-square, W., July 26th, 1930.

CONGENITAL ATRESIA OF THE ŒSOPHAGUS.

To the Editor of THE LANCET.

SIR,—I have lately had under observation a case resembling the one described by Dr. Polson in your issue of July 19th (p. 135).

A female child, a few hours old, was admitted to the Queen's Hospital for Children, Hackney-road, on July 16th, under the care of Dr. Helen Mackay. It was born at full term after an easy labour lasting two hours, weighed 8 lb., and appeared to be a strong healthy infant. On attempting to feed the child it became cyanosed and vomited. On admission to hospital it was dyspnœic, and was vomiting mucus; there was marked retraction of the intercostal spaces. The air passages were cleared as much as possible with a mucus catheter, and the general condition improved. The child became cyanosed and vomited whenever attempts were made to feed it. A radiogram showed an œsophageal pouch.

At autopsy atresia of the œsophagus was found at the level of the upper border of the sternum. The upper segment was dilated to form a sac, the lower was narrowed to form a cord, and was not patent. There was an opening ¼ in. in diameter in the trachea at the level of the bifurcation connecting with the lower segment of the œsophagus. There was complete absence of the septum ventriculorum, but no other congenital abnormality was found.

I am, Sir, yours faithfully,

C. B. SMITH, M.R.C.S.

Queen's Hospital for Children, London, E., July 23rd, 1930.

EOSINOPHILIA IN ASTHMA.

To the Editor of THE LANCET.

SIR,—In a report of the scientific meeting of the Asthma Research Council (THE LANCET, 1930, i., 1293) Dr. Marjorie Gillespie, in describing the eosinophil count in asthma, stated that the highest

ecorded was 57 per cent. A case of asthma submitted to this laboratory for blood examination howed the following percentage of eosinophils.

May	2nd, 18	per cent.	..	Total white count,	20,400.
„	12th, 15	„	..	„	„	„	16,400.
June	2nd, 73	„	..	„	„	„	20,100.
„	6th, 78	„	..	„	„	„	Not done.
„	16th, 71·5	„	..	„	„	„	„
„	30th, 63·5	„	..	„	„	„	„

The possibility of helminth infestation adding to he eosinophilia was excluded by fæces examinations n three occasions. Eosinophilia were also present n the sputum. The patient was having attacks of asthma at irregular intervals, but the blood counts were not done during the attack.

I am, Sir, yours faithfully,

A. HOOD, M.B.,

Major, R.A.M.C., Assistant Director of Pathology, Southern Command.

Poona, India, July 7th, 1930.

CYCLICAL VOMITING.

To the Editor of THE LANCET.

SIR,—The writer of your annotation (July 26th, p. 201) emphasises the constancy with which hypoglycæmia is associated with attacks of this disorder. This has not been my experience. On the contrary, between attacks the blood-sugar is invariably normal, and it does not fall until the attack is well advanced and vomiting has been present for some time, and not always then. Hypoglycæmia in children does not commonly precede or initiate an attack of cyclical vomiting, probably because the glycogen reserves of the liver are never entirely exhausted. The blood-sugar may fall, of course, to a very low level after long-continued vomiting or other causes of starvation. Also there does not seem to be any evidence that hypoglycæmia occurs more frequently in "nervous" than in other children. The beneficial action of sugar in debilitated children would seem to be due to increasing the glycogen reserves, not the concentration of sugar in the blood. The evidence for these statements has been set forth in a recent paper by Dr. H. G. Close and myself in the *Archives of Disease in Childhood*, 1930, v., 149.

I am, Sir, yours faithfully,

London, W., July 28th, 1930. A. ARNOLD OSMAN.

A GENERAL MEDICAL SERVICE.

To the Editor of THE LANCET.

SIR,—I find the leading article with this title in your pages last week a generous appreciation. There are many points in the scheme of the B.M.A. for a general medical service on which further comment might be forthcoming both *pro* and *con*; but I only wish to call attention to the fact that there is here propounded a system of service, and not one of those petty and partial local schemes that have been too often current in conversation. The scheme is one among other indications that at last the medical profession in all its divisions and subdivisions is a primary organ in maintaining a reasonably efficient social organisation. Now that the medical profession sees itself as a vast social instrument, the lay mind should be a little less patronising—less anxious to "keep the doctor in his place" as a mere adviser.

I am, Sir, yours faithfully,

July 30th, 1930. W. LESLIE MACKENZIE.

ROYAL NATIONAL ORTHOPÆDIC HOSPITAL.

To the Editor of THE LANCET.

SIR,—I observe in your issue of to-day you state that last year 354 in-patients were admitted to this hospital, and that this number exceeded all previous totals. The fact is that 2055 in-patients were treated last year; the number of out-patients treated was 9253, and the number of out-patient attendances was 103,254. These figures exceed all previous totals, and do not include the patients treated at the various local clinics. There are now 470 beds in this hospital, including its country branch at Stanmore. I shall be grateful if you will correct the misapprehension which is likely to arise from the figures you publish this week.

I am, Sir, yours faithfully,

ARTHUR MORLEY,
Secretary.

Royal National Orthopædic Hospital, July 26th, 1930.

*** We regret the misprint.—ED. L.

THE TRANSFER OF APPOINTMENTS WITH THE PRACTICE.

To the Editor of THE LANCET.

SIR,—Doctors who may find it necessary to sell their practices owing to ill-health will be well advised to give some little attention to this letter, in connexion with the transfer of appointments recently under the Boards of Guardians. Without arguing the morality or justice of appointments being sold with the rest of a practice, the fact remains that in the past this custom has been usual in the vast majority of cases unless the purchaser has been quite an impossible man, and because as a gesture of loyalty and sympathy to a colleague whose health has broken down, the other doctors in the district have refrained even from applying for such posts.

Things would appear to have changed, in that I have recently been compelled to sell my practice owing to a breakdown in health, and the purchaser has not succeeded to the appointments I held under the Board of Guardians, in spite of the fact that he was officially appointed my deputy when I was granted a month's sick leave and that no complaints were made as to the zeal and efficiency he showed.

My own troubles at the moment are confined to the loss of £500 which I can ill afford, and are as nothing compared to the tragedy that has befallen the purchaser who had saved enough money as an assistant to pay a certain sum down and the rest by instalments, under the impression that he was buying an income that has supported a doctor and his family for 40 or 50 years. He now finds his income cut down by about two-fifths, and how he is going to live and pay off the balance of the purchase money I really don't know, because there can't be any scope for increase in a district that is already over-doctored and is suffering acutely from the competition of State medical services.

I am asking you to be good enough not to disclose my name and address for very obvious reasons, but I enclose my card.

I am, Sir, yours faithfully,

July 18th, 1930. DISAPPOINTED OPTIMIST.

PS.—And it is to be remembered that the State more or less agrees to the sale of a couple of thousand human bodies in the sale of panel practices, and I'm not sure that the State does not actually pay the cost of the notices sent out in such cases!

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS.

BILLS ADVANCED.

IN the House of Lords on Thursday, July 24th, the Adoption of Children (Scotland) and the Education (Scotland) Bills were read a second time. On Friday, July 25th, the Housing (No. 2) Bill was agreed to on Report.

On July 28th, in the House of Lords, the Housing (No. 2) Bill was read the third time and passed. The Education (Scotland) Bill and the Adoption of Children (Scotland) Bill passed through their remaining stages, and were read the third time and passed. On July 29th, in the House of Lords, the Housing (Scotland) Bill was read the third time and passed.

HOUSE OF LORDS.

WEDNESDAY, JULY 23RD.

Royal Veterinary College.

The Earl of HAREWOOD asked the Government if they had investigated the position of the Royal Veterinary College, and what steps they were prepared to take to maintain it; and moved for papers. He said that the College had reached a stage in its career when some action must be taken promptly or the Governors would have to take a step which would eventually lead to the closing of the College—namely, the refusal to accept new students. At present the expenditure of the College exceeded the income, and the buildings were in an irreparable state. During the past three years the Governors had raised £30,000 towards the building fund. The departmental committee which reported last year recommended that the freehold of the site at Camden Town should be purchased for £20,000; secondly, that £280,000 should be spent on erecting new buildings; and, thirdly, that £25,000 should be spent outside London for the purpose of providing a research laboratory affiliated with the College. The committee also recommended that the annual income of the College should be guaranteed at not less than £21,000. He had received a letter from Lord de la Warr stating that the conclusions of the Government—which he hoped were not fixed—were that the sum of £20,000 for the purchase of the freehold should be cancelled while extensive buildings should be erected on the leasehold site at a cost of £250,000 instead of £280,000, which the departmental committee considered was the absolute minimum. He (Lord Harewood) was very doubtful whether £250,000 would be sufficient for the purpose, but the Governors would be willing to consider the Government's offer on that point if they saw any reasonable prospect of securing £250,000 with which to build. The Government's offer was to give pound for pound for the £30,000 which the Governors had in hand, and provide £70,000 in addition. That made £130,000, and the Government added that when the sum collected by the Governors reached £200,000 they would be prepared to recommend to Parliament a further grant of £50,000. From what he knew of the condition of agriculture he scarcely thought that there was the slightest hope of getting that £70,000, and so sure did the chairman of the Governors and the treasurer feel on that point that they informed him that morning that at a meeting of the Governors next week they would recommend that the Governors should refuse the whole of the offer of the Government, because there was no hope of raising a sufficient sum to rebuild the College. They would have to refuse to admit further students into the College. but the actual closing of the College would take about four years, because the Governors were so far committed to the students already there not to close the College before their course of instruction had been definitely completed.

Lord ERNLE said it was a disgrace to the country that this College should be allowed to lapse into extinction. In Berlin the annual sum paid for veterinary science was £280,000, while here it was only £16,000. The College had a chance of becoming affiliated as one of the schools of the University of London, but the University could not be expected to accept a College whose buildings were hopelessly inadequate and whose finances were practically insolvent. Veterinary science was mixed up with the department of public health, and the progress of human pathology and animal pathology had gone hand in hand, as Pasteur and Koch had illustrated.

Earl DE LA WARR (Parliamentary Secretary to the Ministry of Agriculture) said that the offer which the Government made last August to the Governors of the College was that they would give pound for pound up to £100,000. The Governors felt that whether that was a reasonable offer or not, they would not be able to collect sufficient money to make up the sum of £280,000. He took it that what the noble lord would like would be that His Majesty's Government should take over the College completely, rebuild it at the expense of the State, and provide virtually all the maintenance expenses. That would be an entirely new principle in the relations of the State with what amounted to a University department. Hitherto the policy had been that education of university rank should be aided by Government grant, but that the Government did not take the responsibility of maintenance, which was primarily a matter for the governing body. The Government could not accept the view that the entire responsibility for veterinary education should ultimately fall upon the State; but in view of the special circumstances associated with the College the Government had gone up to an offer of 30*s*. per £1 raised. He suggested that the Governors should make an effort to raise the money required, and if they did so they would have all the assistance and encouragement that the Ministry of Agriculture and His Majesty's Government could give them.

After further appeals had been made to the Government by Lord PHILLIMORE, Earl BATHURST, Viscount BRENTFORD, and Lord DANESFORT to save the College,

Earl DE LA WARR said that he could not hold out any hope that the Government would reconsider their decision; but he suggested that Lord Harewood and his friends might have a conference with the Ministry of Agriculture before coming to a decision as to the future of the College.

The Earl of HAREWOOD said that he would see the chairman of the Governors and the treasurer and try to persuade them to take in, at any rate, one further lot of young students if he could hold out any hope that the Government would see them through the absolute expenses necessary for carrying on the course for the next year or two. He withdrew his motion for papers.

HOUSE OF COMMONS.

WEDNESDAY, JULY 23RD.

Naval Stokers and Tuberculosis.

Mr. MARKHAM asked the First Lord of the Admiralty if, in view of the number of stokers invalided yearly out of the service with tuberculosis, he would set up a departmental committee to investigate the cause.—Mr. ALEXANDER replied: The question of tuberculosis in the Services was examined in 1928 by a joint medical services committee, and no useful purpose would be served by appointing a further committee. Methods of combating the disease are constantly under consideration. I may add that the incidence of tuberculosis among this branch of the engine room ratings is not considered to compare unfavourably with the incidence

n the Navy as a whole or with that of the urban civil opulation of England and Wales.

THURSDAY, JULY 24TH.

Accidents to Shop Assistants.

Mr. HOFFMAN asked the Home Secretary what steps he roposed to take, in view of the increasing number of acci- ents which occur, to protect from injury shop assistants mployed in shops where bacon-cutting and other meat- utting, sausage-making, coffee-roasting, and grinding achinery was in use to secure that first-aid outfits were vailable.—Mr. CLYNES replied: I have no statutory owers to intervene except in cases where the part of the remises in which the work is carried on constitutes a actory, but the position has been discussed with the National ederation of Meat Traders, who fully recognise the need for afeguards for meat-cutting and sausage-making machines, nd have taken the matter up with their members on everal occasions. In a few cases where the Factory Act pplies the provisions of the Factory Act relating to fencing nd first-aid have been applied. I am not aware of accidents om the other classes of machine mentioned, but if my on. friend can furnish me with information I shall be lad to look further into the matter.

Artificial Sun-ray Treatment.

Mr. DAY asked the Minister of Health the number of entres approved by his department for the purpose of rtificial sun-ray treatment; and how many applications ad been made to his department by local authorities uring the previous 12 months for the approval of similar entres.—Mr. GREENWOOD replied: 265 such centres had een approved by my department up to April 1st last. uring the previous 12 months 14 applications were eceived from local authorities for approval of similar entres.

Slum Clearance Schemes.

Mr. DAY asked the Minister of Health the number of uildings acquired and demolished for slum clearance hemes since April 1st, 1925; how many new dwellings ad been erected in connexion with slum clearance schemes er the same period; if he could give an approximate timate of the number of persons rehoused in new dwell- gs, and any statistics of the number of persons still living slum habitations.—Mr. GREENWOOD replied: The umber of buildings acquired by local authorities in England nd Wales since April 1st, 1925, in connexion with approved um clearance schemes is approximately 10,700, and the umber demolished approximately 9000. The number of ew dwellings erected since the same date in connexion ith such schemes is rather more than 9700, and it is stimated that some 48,000 persons occupy these new wellings. Statistics on the point raised in the last part f the question are not available.

MONDAY, JULY 28TH.

India and British Medical Supplies.

Mr. GRAHAM WHITE asked the Secretary of State for India he had any evidence as to the effect of the recent decision f the General Medical Council with regard to the rights of ndian medical graduates upon the volume of British trade ith India in medicines and medical appliances.—Mr. EDGWOOD BENN replied: I have no statistics of this trade recent months. I was informed in April last that a oycott of these classes of British goods had been established consequence of the decision of the General Medical ouncil, but in May I heard that this boycott was weakening, nd that orders for British goods were being placed. I have eceived no later reports.

TUESDAY, JULY 29TH.

Poison Gas Experiments with Animals.

Mr. FREEMAN asked the Secretary of State for War what vidence he had, and how it was obtained since 1918, that xperiments conducted at Porton and elsewhere of poison ases on living animals showed that these gases had the same ffects on human beings.—Mr. SANDERS (Financial Secretary o the War Office) replied: My right hon. friend is definitely dvised by his expert advisers that the results of the xperiments are such as to leave no doubt that the methods f curative treatment of the effects of gas which those xperiments suggest are applicable to human beings.

Supply of Medical Officers in the Services.

Dr. VERNON DAVIES asked the Under Secretary of State or Air if the supply of medical officers for that Service was atisfactory; and if any difficulty was experienced in ecruiting officers for the service.—Mr. MONTAGUE replied: here is still some difficulty in obtaining the numbers of edical officers required. The question is one which is constantly engaging the attention of the medical authorities at the Air Ministry and of the Air Council.

Dr. VERNON DAVIES asked the Secretary of State for War the present position with regard to medical officers in the Army; if there were any signs of more satisfactory recruitment to this service; and the reasons for the present position.—Mr. SANDERS replied: The present shortage of regular Royal Army Medical Corps officers is approximately 140, and my right hon. friend is in consultation with the Army Medical Advisory Board as to the causes of this shortage and the possible remedies.

Dr. VERNON DAVIES asked the First Lord of the Admiralty what was the present position with regard to medical officers in the Navy; if there were any signs of more satisfactory recruitment to this service; and, if not, the reason for the present position.—Mr. AMMON (Parliamentary Secretary to the Admiralty) replied: I regret that the shortage of Naval medical officers still continues, and that there are no signs of more satisfactory recruitment. The question is under consideration by the Admiralty.

Infantile Paralysis in Scotland.

Mr. MARCUS asked the Secretary of State for Scotland the number of children under the age of 7 years who died of infantile paralysis during the year 1929; and whether, seeing that the high infantile mortality was largely due to the drinking of impure milk, what steps he proposed to take to ensure a pure milk-supply.—Mr. JOHNSTON replied: During the year 1929, nine children under the age of 7 years died of infantile paralysis in Scotland. As regards the second part of the question, my right hon. friend is advised that the high death-rate among infants is due in the main to causes that cannot be attributed to impure milk. He fully recognises, however, how important a pure milk-supply is to the health of children and of the community generally, and I can assure my hon. friend that the matter is one which is receiving the close attention of the Departments concerned. I am sending him a copy of a circular that the Department of Health for Scotland issued recently on this and other aspects of food administration.

Treatment for Functional Nervous Disorders.

Mr. MANDER asked the Minister of Health if he was aware that, owing to the shortage of accommodation and treatment for persons suffering from functional nervous disorders, a large number of persons would have to be admitted to asylums and become chargeable to the State; and what action he proposed to take.—Mr. GREENWOOD replied: I am unable to agree that the shortage of the facilities to which the hon. Member refers is such as to result in the admission of a large number of persons to mental hospitals. I have already explained to the hon. Member that under the Mental Treatment Act local authorities (with whom, and not with the State, rests the financial responsibility for these patients), are given extensive powers to provide for the preventive treatment of incipient mental illness. The position under the Act has been fully explored in a two-days' conference with Visiting Committees, and I do not think that any further action could usefully be taken at present.

In the résumé of the debate in Committee of Supply on the vote for Health Administration in Scotland we regret that, through a mechanical error, the valuable contribution from Sir Robert Hamilton became attributed, mostly, to Sir John Gilmour.

A LEICESTER CHILDREN'S CONVALESCENT HOME.—On Monday last the first patients were admitted to the Roecliffe Manor Convalescent Home, near Leicester, which has been bought and adapted by the Leicester and County Hospital Saturday Society. It contains 50 beds for boys and girls between 3 and 14 years. Since its foundation in 1903 the society has raised £633,000, of which Leicester Infirmary has received £402,000; the remainder has been spent on convalescent treatment.

MANCHESTER TUBERCULOSIS DISPENSARY.—Judgment was given on July 22nd by Mr. Justice Maughan in the Chancery Division in the action of the proprietor of the Rivoli Cinema against the Manchester Corporation that the corporation had no power to build a tuberculosis dispensary on a site opposite the infirmary and bounded by Oxford-road, Denmark-road, and Aberdeen-street. It had been an open space for many years. The corporation had previously obtained the approval of the Ministry of Health to the building of the dispensary. His lordship held that no public right of way had been acquired over the land, and held that the approval of the Ministry of Health had given the corporation authority to use the land for the purpose which had been approved.

MEDICAL NEWS

University of London.

At recent examinations the following candidates were successful:—

M.D.

Branch I, Medicine.—R. G. Anderson, St. Bart.'s Hosp; J. R. Blazé, Ceylon Med. Coll. and Univ. Coll. Hosp.; P. E. J. Cutting, St. Bart.'s Hosp.; Hari Das, Univ. Coll. Hosp.; T. A. Davies (University Medal), St. Thomas's Hosp.; R. E. Ford, London Hosp.; L. W. Hale, Univ. Coll. Hosp.; S. W. Hardwick, St. Bart.'s Hosp.; J. C. Hawksley, Univ. Coll. Hosp.; E. G. Housden, St. Thomas's Hosp.; C. A. Keele, Middlesex Hosp.; C. W. Marshall, Guy's Hosp.; S. P. Meadows, Univ. of Liverpool and St. Thomas's Hosp.; A. J. Morland, Univ. Coll. Hosp. and Univ. of Lausanne; R. H. Morley, Univ. of Leeds; Thomas Morton, St. Thomas's Hosp.; A. M. Richards, Univ. Coll. Hosp.; Gwladys V. Smallpeice, London (R.F.H.) Sch. of Med. for Women; Emrys Williams, St. Thomas's Hosp.; and William Yeoman, Univ. Coll. Hosp.

Branch II, Pathology.—K. T. Gajjar, Univ. Coll. Hosp.; and Dorothy S. Russell (University Medal), London Hosp.

Branch IV, Midwifery and Diseases of Women.—W. M. Brown, Guy's Hosp.; Elizabeth J. Carpenter, London (R.F.H.) Sch. of Med. for Women; G. M. FitzGibbon, St. Thomas's Hosp.; E. E. D. Gray and E. H. Roche, Guy's Hosp.; Iris V. I. Ward, London (R.F.H.) Sch. of Med. for Women; and Jane C. Williams, St. Mary's Hosp.

Branch VI, Tropical Medicine.—Frank Marsh, Guy's Hosp.

M.S.

Branch I, Surgery.—A. E. de Chazal, Univ. Coll. Hosp.; K. W. Heritage, London Hosp.; and Ivor Lewis, Univ. Coll. Hosp.

University of Edinburgh.

At a graduation ceremonial on July 23rd the following degrees were conferred:—

M.D.—J. R. Dogra,**† R. O. Eaton,* W. C. Fothergill,† J. S. Fulton,*** Anne Gibson, O. K. G. Guyer, C. I. Irvine-Jones, J. P. S. Jamieson, John Lowe, J. E. Maccabe, A. A. S. M'Donald, Bessie R. Mackenzie, F. G. Macnair, J. C. Moir,*** David Pottinger,† A. L. K. Rankin,* F. E. Reynolds,*** J. B. Rolt, D. R. Thapar, Mary Turton (*née* Martin), William Waddell, and H. E. Y. White.

Ch.M.—A. S. Fry.

The degrees of M.B. and Ch.B. were conferred on the candidates whose names were given on p. 221 of THE LANCET last week (with the exception of W. R. de Faria) and on Margaret L. Mackay. The following diplomas were also granted:—

Diploma in Psychiatry.—W. J. Raitt.†

Diploma in Radiology.—J. S. Fulton, Y. N. Krishnamoorty,† S. K. Montgomery,† K. R. Speeding,† J. C. Tainsh, and A. G. C. Taylor.†

*** Gold Medal for Thesis. ** Highly commended for Thesis. * Commended for Thesis. † In absentia.

The Cameron Prize in practical therapeutics has been awarded to Dr. George Richards Minot and Dr. William Parry Murphy "in recognition of their discovery of the treatment of pernicious anæmia by the administration of liver."

University of Manchester.

Mr. J. P. Buckley has been appointed lecturer in surgical pathology; Mr. Harry Platt and Mr. D. McKay Sutherland lecturers in applied anatomy; and Mr. A. Graham Bryce lecturer in regional surgery.

Dr. F. H. Lacey, Mr. D. P. Sutherland, and Dr. William Susman have been appointed members of the Board of the Faculty of Medicine.

University of Sydney.

The Senate has announced that the Rockefeller Foundation has decided to contribute £100,000 to provide laboratory facilities for the departments of medicine, surgery, pathology, and bacteriology. The recent establishment of full-time Bosch chairs in medicine, surgery, and bacteriology has brought the medical school of the University within the scope of the activities of the Foundation. It is the intention of the university to build a new block close to the Royal Prince Alfred Hospital. The present medical school will continue to house the departments of anatomy, physiology, pharmacy, and dentistry. The new block will take in the departments of medicine, surgery, pathology, and bacteriology as well as departments which have already been endowed. An account of the new school of Public Health and Tropical Medicine at Sydney lately appeared in THE LANCET (1930, i., 1195).

Society of Medical Officers of Health.

The annual Neech prize for the best paper read before branch or group of this society has been awarded for th session 1928–29 to Dr. J. Sim Wallace for his address o the Prevention of Dental Caries, published in *Public Healt* in February, 1929. The award has been delayed to allo publication of all the papers submitted for consideratio by the assessors.

Fellowship of Medicine and Post-Graduate Medica Association.

From August 5th to 30th an afternoon and evening course consisting of clinical and cystoscopic demonstrations, wi be given at the All Saints' Hospital, Vauxhall Bridge-roa Demonstrations will be given on both male and femal patients. Particulars of operations may be had from th hospital. An all-day course in Diseases of the Chest wi be held at the Brompton Hospital from August 11th to 16th In September there will be a course in Diseases of Childre at the Queen's Hospital from the 1st to the 13th, and on in Medicine, Surgery, and the Specialties at the Wes minster Hospital from the 15th to the 27th. Copies of a syllabuses and a programme for the winter months ma be had from the secretary of the Fellowship at 1, Wimpol street, London, W. 1. A provisional list of special cours for 1931 is now available.

Founder's Day at Epsom College.

On July 26th Lord Burnham presented prizes to 7 successful boys and happily refrained from offering to th rest the usual consolatory phrases. His eloquent speec was largely in praise of Lord Rosebery, his predecessor, president of the school, and in appreciation of the achiev ments and ideals of Epsom College. The headmaster, M A. Powell, reported a gratifying series of academic an athletic successes among past and present Epsomians, an announced the decision of the Council to proceed with th building of a new sanatorium which is to cost £25,000 an to be a model of its kind. The existing sanatorium will be co verted into a house for 40 boys, bringing the total accon modation up to 450. Dr. Raymond Crawfurd, as chairma of the Council, thanked Lord Burnham for coming, an gave an account of distinguished holders of the office president since the College was founded in 1853. Th entertainments offered to parents and guests included th annual cricket match against a team of Old Epsomians, a assault-at-arms, and in the evening a spirited performan of "The Gondoliers" by the school choral society.

A Military Medical Museum.

On July 26th, at the Duke of York's Headquarter Chelsea, Lieut.-General H. B. Fawcus, Director-Gener of Medical Services, opened a museum which has bee instituted by the officers of the 47th Division, R.A.M.C (T.A.), for the purpose of instructing the men in anatom physiology, hygiene, field sanitation, first-aid, and arm nursing. General Fawcus and Mrs. Fawcus were receive by the A.D.M.S., Lieut.-Colonel L. D. Bailey, and after a inspection of the guard of honour provided by the R.A.M.C units of the Division the General was presented with key with which he formally opened the museum. Gener Fawcus said that the officers of the Division had bee endeavouring to attract a better type of man into the rank and had realised that in so doing they must provide for hi an intellectual interest and a means of learning his wo thoroughly and intelligently. He expressed great appr ciation of the work already done in connexion with th establishment of the museum, the collection of specimen models, and diagrams, and observed that the officers of th Division were evidently not men who let grass grow und their feet. He congratulated them on their activitie and foresaw for the museum a wide and ever-increasin usefulness. Colonel Bailey thanked General Fawcus f coming to open the museum; it was one more proof of th interest he had always shown in the activities of the Ter torials. The museum was in its infancy, but already ver precious to the R.A.M.C. units of the 47th. He thanke the Territorial Association for bearing the expense decorating the room, and numerous donors for the gifts furniture, specimens, models, and the like. He announce that regular weekly lectures would be given in the museu by experts in the various subjects relevant to the R.A.M.C training. Captain H. A. C. Gregory seconded the vote thanks.

London School of Hygiene and Tropical Medicine.

Every second year, in memory of the late Dr. Cowas Lalcaca, a silver medal is awarded to a student of this school for the best essay on clinical medicine and surgery in the tropics. The competition is open to any student who has obtained the school certificate. The next award will be made in the autumn of 1931.

"Hospital Ballots."

Under this title the Hospitals Automatic Ballot Association, Ltd., is inaugurating a system of competitions in aid of hospital funds by means of automatic machines. By placing a shilling in the machine an entry form for a competition, "simple tests of skill and judgment," will be delivered. Prizes amounting to £2000 will be given in each competition, the first of which will be in aid of the reconstruction fund of St. Bartholomew's Hospital. It is calculated that the expenses, including the rent of sites for the machines, will be 20 per cent. of the receipts, and after deducting from the remaining 80 per cent. the cost of the prizes and small expenses connected with them, the balance will be distributed to the hospitals. It is stated that 1000 automatic machines are at once to be distributed in and around London and the south-east of England; some are already in position. The trustees of the scheme are Field-Marshal Sir Claude Jacob, Sir Gordon Campbell, and Sir D'Arcy Power, and the judges of the competitions are Sir Francis Goodenough, Mr. Edgar Wallace, and Mr. Gilbert Frankau.

Reunion of War-blinded Masseurs.

Under the auspices of St. Dunstan's the annual luncheon and reunion of blinded soldier masseurs was held at the Langham Hotel, London, on July 25th. Captain Ian Fraser presided over a gathering which included nearly 70 masseurs and numerous representatives of the medical profession and public bodies. The chairman said that the Prince of Wales had heard with very great pleasure of the success attained by more than 100 blinded soldiers who had been trained as masseurs and medical electricians. The primary object of the luncheon was to do honour to the masseurs, who were an outstanding example of the success which St. Dunstan's men had achieved. The secondary purpose was to give an opportunity of referring to the medical profession in general. The St. Dunstan's family consisted of some 2000 men and 5000 wives and children, and the health of this large group had become a big responsibility. He wished to place on record their appreciation of the services of the medical profession and hospitals throughout the country. Nearly 2000 men had been blinded in the late war. Sir Arnold Lawson and Major A. W. Ormond had compiled statistics showing that in 41 per cent. of the cases blindness was due to wounds from high explosives or bombs, in 29 per cent. to bullet wounds, and 27 per cent. to non-traumatic causes, such as detachment of the retina, cataract, and optic atrophy, and the aggravation of conditions which might have been latent but for war service. Up and down the country these men required the help of the medical profession, and it was given generously.—Sir Thomas Horder, proposing the toast of Our Patients, spoke of his interest in physical therapy—"a series of ancillary methods of treating patients which begins with the human hand." It was common knowledge that the blind had a peculiar facility for massage. Some people were visualists, others were auditives, and he had no doubt that some were primarily tactualists. The blind in his audience were obviously auditive, but they were making themselves effective and skilled tactualists. In physical therapy he preferred simple to complex methods, but patients were impressed by machinery and there was a danger that the human hand would be put in the background. An enormous field lay open for progress in massage and manipulation. At the present time he thought there was, perhaps, too great a tendency to substitute so-called passive movement for active movement. No amount of massage or electrical stimulation had the same physiological value as a natural movement carried out by the patient under supervision and careful guidance. The moral effect of the masseur's work was tremendous, and his health and personality had a definite value apart from the treatment he gave with his hands. Coöperation with the doctor was essential, and in case of doubt about the value of treatment it was the masseur's duty to give his views to the medical man in charge of the case.—Mr. Edmund Toft, in proposing Sir Thomas's health, said that the masseurs' ambition was to prove themselves as worthy in the war against disease as in the war in which they lost their sight. They were dependent on the profession for the success of their work.—Sir Neville Pearson gave the toast of The Guests, coupled with the name of Mr. R. C. Elmslie, F.R.C.S., chairman of the Chartered Society of Medical Massage and Gymnastics, who responded.

Municipal Grant to Voluntary Hospital.

East Ham town council has decided to make a grant of £3000 per annum to East Ham Memorial Hospital on condition that certain services are provided and that the council has five representatives on the management committee and a medical representative on the medical committee.

Enlargement of London Temperance Hospital.

This institution in Hampstead-road, N.W., is being enlarged. A new wing is to be built for the pathological, electrical, massage, and sunlight departments, with additional accommodation for the nursing staff and private patients. This work has been made possible by the children, grandchildren, and great-grandchildren of the late Mr. and Mrs. Samuel Insull, who took an active part in the work of the hospital in its early days. The new building is consequently to be called the "Insull Memorial Extension."

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, August 4th, to SATURDAY, August 9th.—ALL SAINTS' HOSPITAL, Vauxhall Bridge-road, S.W., Afternoon and Evening Course of Clinical and Cystoscopic Demonstrations (Male and Female). Four weeks. Further particulars from the Fellowship of Medicine.

Appointments

BROWN, C. M., M.B., Ch.B. Glasg., has been appointed Tuberculosis Medical Officer for Hull.

FRASER, A. MACK., M.D., Ch.B. Aberd., D.P.H., Medical Officer of Health, Inverness.

MURPHY, J. C., L.R.C.P.I., L.R.C.S.I., Medical Officer, Terryglass Dispensary District, Tipperary.

SKENE, G. W. R., M.D., Ch.B. Edin., Vice-Chairman of the Willesden Hospital Council.

King's College Hospital: J. G. Y. BELL, M.B., F.R.C.S., Junior Urological Surgeon; F. GOLDBY, M.B., M.R.C.P., Assistant Pathologist.

Certifying Surgeons under the Factory and Workshop Acts: ANDREWS, H. A., L.R.C.P. Lond., M.R.C.S. (Tonbridge); MCLEISH, H., M.B., Ch.B. St. And. (Cupar, Fife).

Births, Marriages, and Deaths

BIRTHS.

FILMER.—On July 18th, at Wilbraham-place, S.W., the wife of Harold E. Filmer, M.R.C.S., L.R.C.P., of a daughter.

PENRY.—On July 13th, at Priory Dene, 33, West Cliff-road, Bournemouth, to Frances Phelps Penry, wife of John Penry, M.R.C.S., L.R.C.P.—a daughter.

MARRIAGES.

MCCAHON—WHIGHT.—On July 24th, at St. Olave's Woodberry Down, Albert Edward McCahon, M.B., Ch.B., of Stoke Newington (late of Kilrea, Ulster), to Kathleen, only daughter of Mr. and Mrs. Arthur Whight, of Allerton-road, Lordship Park.

PUDDY—BARBER.—On July 22nd, at Easthampstead Parish Church, Eric Ivimy Puddy, M.B., B.S., to Patience Elizabeth Barber, daughter of the late Percy Barber, of Charlton Court, Tetbury, Glos., and of Mrs. Lawrence Mitchell, of Bracknell, Berks.

DEATHS.

MASON.—On July 25th, at Portland-court, W., J. Wallis B. Mason, M.D., late of Osnaburgh-terrace, N.W., in his 77th year.

MASSON.—On July 27th, as the result of a motor accident, John Masson, M.D., aged 71.

MILLER.—At Ravelston-place, Edinburgh, Hugh Miller, M.B., Ch.B., Regional Medical Officer, Dundee, of Daylesford, Newport, Fife, late of Hamilton and Stow-on-the-Wold.

NIALL.—On July 23rd, Eugene Michael Niall, M.D., of Arlington-street, Piccadilly, S.W.

O'SULLIVAN.—On July 17th, at Kinsale, Ireland, Danie O'Sullivan, M.R.C.S., L.R.C.P., aged 60.

SOLTAU.—On July 26th, in London, Alfred Bertram Soltau, C.M.G., C.B.E., F.R.C.S., F.R.C.P., M.B., M.D., of Plymouth, in his 55th year.

WELLS.—On July 25th, at Castle Hill Lodge, Maidenhead, Charles Wells, M.D., after long illness, aged 81 years.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages and Deaths.

NOTES, COMMENTS, AND ABSTRACTS

DISTRIBUTION OF BLOOD GROUPS IN SOUTH AMERICAN INDIANS.

By GERALD GOLDEN, M.B. LOND.

L. and H. Hirszfeld [1] were the first to draw attention to the possible ethnological significance of the distribution of blood groups. They made numerous observations during the war among the many different nationalities represented in the Macedonian campaign. They found that the populations of Western Europe are characterised by a high proportion of groups II. and IV. (Moss), and a low frequency of group III. Negroes and many of the Asiatic races, on the other hand, show an almost equal proportion of groups II. and III., while some of the Eastern Asiatics show a preponderance of group III. From west to east there is a fairly steady decrease in group II. individuals and an increase of group III. Group I. is always a rare group, as it contains both agglutinogens, while group IV. is generally represented by between 30 and 50 per cent. A few typical figures are given :—

	I.	II.	III.	IV.
	Per cent.			
500 Englishmen	3	43	7	47
500 Germans..	9	40	13	38
300 Russians (Moscow) ..	8	39	20	33
1000 Hindus	9	19	41	31
500 Negroes (Belgian Congo)	8	22	24	46

These observations led the Hirszfelds to suggest that there were in reality two main stocks of the human race, represented respectively by the agglutinogens A and B of groups II. and III. ; it was assumed that a great deal of intermarriage had taken place, accounting thus for the representation of all groups in every race. This hypothesis led to much research to find out whether the inheritance of group properties were indeed so exact as to be of racial significance. The results of these investigations have led to a general belief that the agglutinogens are racially characteristic. Historical evidence has in several instances born testimony to the soundness of the hypothesis.

Verzar and Weszeczky [2] have examined the group distribution in three quite distinct ethnical nuclei of population in Hungary. These include German colonies dating back to the beginning of the eighteenth century, the Magyars, whose origin was the Urals, and who seem to be related racially to the Turks, and finally the Tziganes coming from India. The comparison between each group of Hungarians and the races from which they sprang shows how the serum characteristics have been maintained.

	I.	II.	III.	IV.
	Per cent.			
German colonists	3	43	13	41
Magyars	12	38	19	31
Tziganes	6	21	39	34
Germans	9	40	13	38
Turks	7	38	19	36
Hindus..	9	19	41	31

Several other instances are recorded which show evidence of a similar nature. On the other hand, it is not easy to understand the marked difference between the groups among Hindus and the Western European races, between which, on other grounds, there seems to be an historical kinship.

Since the Hirszfelds announced their hypothesis, observations have been made among the red Indian survivors of North America. Whereas the white population of the United States shows figures almost identical with those of Western Europe, the Indians show a strikingly different distribution.

The results recorded are as follows:—

	I.	II.	III.	IV.
	Per cent.			
1000 U.S.A. whites (Snyder [3])	3	42	10	45
1134 Red Indians ,,	1	16	4	79

The Esquimaux and some of the Indians of the Argentine Chaco show a similarly great preponderance of group IV. These figures have led Bernstein [4] to make the suggestion that there are three rather than two distinct stocks, represented by groups II., III. and IV. Thus the characteristic of this further racial stock is the absence of agglutinogens.

Blood Groups of a Brazilian Indian Tribe.

My own observations have been made on Brazilian Indians belonging to the Caraja tribe. Although the total number of blood examinations made, including controls, does not much exceed 100, the results are of interest because they are, I believe, the first records of the kind among the million and a half odd Indians in Brazil, and because they differ markedly from any other figures so far published.

The method used was a modification of Beth-Vincent's, which affords the simplest means of identifying the agglutinogens, and is the most easy to carry out.

Two stock sera are required, belonging to groups II. and III. These should contain a reasonably high titre of the agglutinins B and A, which respectively characterise these groups. A drop of each serum is placed separately on a glass slide or porcelain dish, and a drop of the blood to be examined is added to each. If agglutination occurs it can be readily detected by the naked eye as a red precipitate like brick-dust, which takes the place of the homogeneous red mixture. With very rare exceptions this change occurs within less than a minute, and is quite obvious. Additional certainty may be obtained by using the microscope. Under the low power, the agglutinated mixture shows the red corpuscles heaped together in irregular dense masses which are quite different from the rouleaux formation occasionally assumed by the corpuscles in any blood which is allowed to stand.

In obtaining the figures given below, Beth-Vincent's method was modified as regards the proportion of blood to stock serum. Instead of adding a drop of serum to a drop of blood, the end of a thin glass rod was used to transfer a smear of blood from the pricked finger to the serum. In this way the mixture showed a proportion of blood to serum approximately between 1 : 10 and 1 : 5 instead of equal parts. This is a decided advantage, because there is very much less chance of mistaking rouleaux formation for agglutination when the blood is well diluted.

Stock sera were obtained by the kindness of Dr. Vital Brasil, whose name is associated with much important work in immunology.

Sixty-one observations were made among the Caraja Indians, and though the method is simple they were the product of more effort and patience than might be imagined. The Carajas can only be reached after a journey from the coast of a thousand miles overland by rail and automobile to the point of embarkation on the river Araguaya, followed by a 400 miles trip down stream by canoe. Though their tribe probably does not number more than 800 in all it is composed of tiny villages scattered over the course of the Araguaya for a distance of 500 miles. Once arrived among them, the difficulties are but begun. It is only after a great deal of palaver, and a great many demonstrations on his comrades, that the inquisitive white man is allowed to draw the drop of Indian blood. The first to submit to this new form of torture were always a few old widows who looked hungrily at the big bricks of sugar offered as a reward to the brave. They thought any risk worth running for so substantial an addition to their miserable ration. When it was seen that they survived the ordeal so well, children came forward and finally a few of the timid young warriors submitted too.

The results showed that of the 61 Indians :—

3 (5%) belonged to group I.
3 (5%) ,, ,, II.
31 (51%) ,, ,, III.
24 (39%) ,, ,, IV.

As a control, 43 persons of Brazilian nationality were examined in a town some 500 miles distant from the country inhabited by the Carajas Indians. Like most Brazilian towns of the interior, its population is a more or less intimate mixture of black and white. The figures obtained are as follows :—

21 (49%) belonged to group II.
3 (7%) ,, ,, III.
19 (44%) ,, ,, IV.
No group I. individuals were found.

Considering the above observations, it is at once evident that the number of Indians examined is insufficient to serve as a basis for any exact statement of the distribution of the blood groups. On the other hand, the preponderance of the groups III. and IV. is sufficiently overwhelming to show that these two groups are characteristic of the tribe. Further, it should be noted that the 43 controls give figures very closely resembling those quoted by J. Montenegro [5] for 120 Brazilians living in the State of Sao Paulo. Montenegro's figures are : group I., 3 per cent. ; group II., 41 per cent. ; group III. 9 per cent. and group IV., 47 per cent. 1685 cases examined by Duarte [6] in the State of Bahia showed : group I., 2 per cent. ; group II., 30 per cent. ; group III., 8 per cent. ; and group IV., 39 per cent. The large negro element in Bahia makes the figures approximate more closely than those of other Brazilian States to the figures already quoted for the Belgian Congo.

Comment.

In the figures for the Caraja Indians there are two points worthy of special note. In the first place, there is no record of any other race showing so high a preponderance of group III. individuals. The Hindus, already mentioned, show 41 per cent. in group III. Even in their figures, however, there is not such a disparity between groups II. and III. as among the Carajas. Even allowing for errors due to the small numbers examined, this disparity is very striking. The second point is the wide difference between the figures of the Carajas and those of the Red Indians of North America. Unfortunately, the only other figure available for South American Indians is that of S. Mazza and J. Franke,[7] who found 83 per cent. of group IV. in the inhabitants of the Argentine Chaco (quoted by Lattes [8]).

The Carajas are a tribe of river Indians living in a part of Brazil which is practically destitute of settlers. They do not appear either to have made war with the latter or to have entered into any close relations with them. Their attitude is friendly, but reserved, and the instances of intermarriage between Carajas and settlers are extremely rare. On all sides they are surrounded by other more or less savage tribes. Their language and the customs of these Indians have led to the opinion that they do not belong to the same ethnological group as the Tupy-Guarani races of Argentina and Paraguay. Observations made among the Carajas from the serological standpoint lend further support to this view. Although it is still much too early to draw conclusions, it is reasonable to suggest that the Carajas are descended from a mixture of two stocks—the Eastern Asiatic characterised by group III., and the ancestors of the Red Indians of North America, who are very largely group IV. individuals. The well-known disinclination of Indian people to mix with other races perhaps accounts for the much more uneven distribution of groups among them than among European and Asiatic races. It will be noted that the Carajas exemplify these peculiarities.

It is to be expected that fresh light will be thrown on all these matters as figures are obtained for many more of the tribes of Brazil and South America in general. Perhaps then, and then only, the problems of racial origins among these primitive peoples will be fully understood.

THE ANTISCORBUTIC VITAMIN IN APPLES.

THE apple has not been considered in the past as a good source of the scurvy preventing vitamin. In a report [1] just issued by the Medical Research Council, however, M. F. Bracewell, E. Hoyle, and S. S. Zilva describe very considerable differences in the anti-scorbutic content of apples according to the variety. Of all the home grown and colonial varieties tested by them the English cooking apple known as Bramley's Seedling was found to be decidedly the most active. The relatively high activity of this apple is apparently one of its hereditary characteristics, and is not related in any way to the soil in which it is produced. The age of the tree or the conditions under which the apples are cultivated have no apparent influence on the amount of antiscorbutic vitamin in the fruit. The Dabinett, a cider variety, ranked next to Bramley's Seedling and Cox's Orange Pippin came third in the list in respect of antiscorbutic activity. Canadian dessert apples had almost the same activity as corresponding English varieties, whereas Australian and New Zealand apples were not as potent. The fall in the potency of the last-mentioned group is probably related to the increased time that elapsed between the picking and testing of the fruit. Little loss was found in the antiscorbutic activity of English grown apples during three months storage in air at 1° C. Storage in a mixture of carbon dioxide, nitrogen, and oxygen at 10° C. for the same period produced a definitely greater loss of activity. It was found that baking apples in their skins for 50 minutes till the flesh was quite soft scarcely affected their antiscorbutic potency. It is hoped that a continuation of experiments on these lines may throw further light on the physiological properties of the antiscorbutic vitamin, and even help to reveal its identity. Meanwhile, it is of some practical importance to have established the fact that relatively potent antiscorbutic apples can be produced.

THE PROFESSIONAL CLASSES AID COUNCIL.

THIS Council exists for the relief of distress among members of the professional classes, and its procedure is to avoid doles and give immediate pecuniary help when needed. The Council has just issued its ninth annual report which shows that its operations are continually increasing. During the year, May 1929 to April 1930, 1077 applications have been considered as against 920 last year, and financial assistance has been given to 239 families, 25 persons have received grants of clothing, and advice has been given to 277 applicants—this last being often an extremely valuable form of assistance. It is regrettable that the total income of the Council shows a drop of nearly 10 per cent., while the amount spent in relief has increased by nearly 7 per cent., and the Council plead for an increased donation list in view alike of past responsibilities and future activities. The fund justifies every request on its behalf, and the address of the Council is 251, Brompton-road, S.W.3.

IN THE MATTER OF AGE-LIMIT.

To the Editor of THE LANCET.

SIR,—The letter from "Ex-Temporary Civil Servant" in your current issue is timely. I, too, find all roads barred because I am aged 49 years; indeed, I see that a practitioner aged 27 to 30 years is, in your advertisements, considered to be experienced. My own experience is as follows: early successes and resident experience, honorary physician to two important hospitals, and post-graduate study under Sir James Mackenzie. On the outbreak of war, being in the colonies, I came to England at my own expense. I served in France in the front line in 1915–16. I was consulting physician on heart disease in Salonika, 1917–18; Chairman of the Special Medical Board for Civil Servants (Ministry of National Service) and Chairman of the Consulting Board at Chancery-lane; Staff Deputy Commissioner of Medical Services to the first decentralised Region of the Ministry of Pensions; Commissioner of Medical Services for Yorkshire (Ministry of Pensions), with final decision on medical matters, the control of 32 medical boards, many treatment clinics, and hospitals containing nearly 3000 beds, while my signature covered an expenditure of at least £3,000,000 per annum. I find myself now debarred from any work under the Government, under local authorities, and even privately, because I am too old.

I am, Sir, yours faithfully,

ANOTHER EX-TEMPORARY CIVIL SERVANT.

July 26th, 1930.

STERILISING WATER BY THE CATADYN METHOD OF KRAUSE.

About 50 years ago the Swiss biologist, Carl v. Nägeli, made the observation that micro-organisms died in water which was kept for several weeks on end in vessels of silver or copper. He could offer no explanation of this effect, as he was unable to detect the presence of any metal in solution and his experiments precluded the possibility of the germs having been killed by radiation. He called the phenomenon "oligodynamics," and after his death Dr. G. A. Krause, Munich, a physicist, and others, confirmed and extended his observations. The catalytic-dynamic properties of finely divided silver have been utilised in the "catadyn" method of sterilising water. The effect of minute quantities of the spongy metal distributed over porcelain rings, beads, or particles of sand on the living organisms in water has been accurately measured; in most instances the colon bacillus has been taken as the test organism. It is claimed that the filtrate also in some mysterious way acquires and retains the germicidal power originating in the materials of the catadyn process. Severe and prolonged critical tests have been applied and the evidence advanced is remarkably convincing. Before it can be applied on a commercial scale the question of expense of materials and containing vessels will require scrutiny, but a prima facie case has been made out for the consideration of the physicist, the biologist, and the public health expert. A demonstration of the method before an informed audience would seem to be the next step.

THE MEDICAL DIRECTORY.

To the Editor of THE LANCET.

SIR,—The annual circular has been posted to each member of the medical profession. If the form has not been received, a duplicate will be sent on request. We shall be grateful for the return of the forms by an early post.—We are, Sir, yours faithfully,

J. AND A. CHURCHILL.

Gloucester-place, W., July 29th, 1930.

WESTBURY COTTAGE HOSPITAL.—The hospital is about to be rebuilt at a cost of £9500. There will be 20 beds, two of them in a private ward.

Vacancies

For further information refer to the advertisement columns.

Altrincham General Hospital, Cheshire.—Sen. H.S., and Jun. H.S. At rate of £150 and £120 respectively.
Barnsley, Beckett Hospital and Dispensary.—H.P. £140.
Barnstaple, North Devon Infirmary.—Res. M.O. At rate of £150.
Bath, Royal United Hospital.—Asst. H.S. At rate of £120.
Birmingham, City Hospital, Little Bromwich.—3rd and Jun. Asst. M.O.'s. £350 and £300 respectively.
Birmingham General Hospital.—Res. H.P. £70.
Birmingham, Midland Hospital, Easy-row.—H.S. £200.
Bradford, Royal Eye and Ear Hospital.—Jun. H.S. £150.
Brentwood, Essex, High Wood Hospital for Children.—Asst. M.O. £550.
Brighton, Royal Sussex County Hospital.—Cas. H.S. £120.
Cardiff, Welsh National School of Medicine.—Demonstrator in Pathology and Bacteriology. £250.
Chester County Mental Hospital.—Jun. Asst. M.O. £350.
Chesterfield and North Derbyshire Royal Hospital.—H.S. At rate of £100–£175.
Colchester, Essex County Hospital.—Asst. H.S. and Registrar. £120.
Croydon County Borough, P.H. Dept.—Asst. M.O.H. for Obstetrics. £600.
Derbyshire Royal Infirmary, Derby.—Ophth. H.S. £150.
Doncaster Royal Infirmary.—Three H.S.'s and one H.P. All at rate of £200.
Dudley, Guest Hospital and Eye Infirmary.—Asst. H.S. £150.
Durham County Council.—District Tuber. M.O. £500.
Durham County Sanatorium, Holywood Hall, Wolsingham.—Locum. Seven to 9 guineas weekly.
East Ham Memorial Hospital, Shrewsbury-road, E.—H.S. to Special Depts. and Cas. O. At rate of £120.
Glasgow Univ.—Samson Gemmell Chair of Medical Pædiatrics.
Gloucester, Gloucestershire Royal Infirmary and Eye Institution.—Res. Surg. O. Also H.P. At rate of £200 and £135 respectively.
Golden-square Throat, Nose and Ear Hospital, W.—H.S. £100.
Halifax Royal Infirmary.—3rd H.S. £125.
Hertford County Hospital.—H.P. At rate of £150.
Huddersfield Royal Infirmary.—H.S. At rate of £150.
Ilford, King George Hospital.—Res. M.O. £200.
Kilmarnock Infirmary, Ayrshire.—Res. M.O. £140.
Lancaster, County Mental Hospital.—Temporary Asst. M.O. Seven guineas weekly.
Manchester, Royal Infirmary, Roby-street.—Jun. H.S. and Cas. O. £100–£200. Also Four Technical Assts. for Clin. Lab. work. Each £200.
Manchester University.—Amy Henrietta Worswick Fellowship. £150.
Manchester, Victoria Memorial Jewish Hospital.—Hon. Surgeon
Manitoba University.—Professor and Asst. Professor of Anatomy. $5000 and $3500 respectively.
Margate and District New General Hospital.—Res. M.O. £125.
Marseilles, Queen Alexandra Memorial Hospital.—Res. M.O. £250.
Merthyr General Hospital.—Res. H.S. At rate of £150.
Newark General Hospital.—Res. H.S. At rate of £175.
Nottingham, Hospital for Women.—H.S. At rate of £150.
Nottingham and Midland Eye Infirmary.—Res. H.S. £200.
Plymouth, South Devon and East Cornwall Hospital.—Hon. P. and Hon. Asst. P.
Queen's Hospital for Children, Hackney-road, E.—Cas. O. At rate of £100.
Richmond, Surrey, Royal Hospital.—Jun. H.S. At rate of £100.
Rochdale Infirmary and Dispensary.—Jun. H.S. £175.
Romford, Essex, Oldchurch Hospital.—Res. 2nd and 3rd Asst. M.O.'s. Each £250.
Saint Mark's Hospital for Cancer, Fistula, &c., City-road, E.C.—Res. Surg. O. At rate of £150.
Salford, Hope Hospital.—Res. Surg. O. £400.
Sheffield National Radium Centre.—Medico-Physicist. £600-£800
Sheffield Royal Hospital.—Res. Anæsthetist. At rate of £80.
Sheffield Royal Infirmary.—H.S. At rate of £80.
Shrewsbury, Royal Salop Infirmary.—Res. H.S. At rate of £160
Southampton Borough Hospital.—Res. M.O. £350.
Truro, Royal Cornwall Infirmary.—H.S. £170.
Walsall General Hospital.—Cas. H.S. At rate of £120.
Walsall Manor Hospital.—1st and 2nd Asst. M.O.'s. £200 and £150 respectively.
West Ham County Borough.—Deputy M.O.H. £850.
Willesden General Hospital, N.W.—Registrars.
Winchester, Royal Hampshire County Hospital.—Sen. Res. M.O. £200. Also H.S. £150.
Wolverhampton, Royal Hospital.—Cas. O. and Res. Anæsthetist. At rate of £125.

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Somercotes (Lincolnshire) Pontesbury (Shropshire); and at Neath (Glamorganshire).

The Secretary of State for the Home Department gives notice of a vacancy for an Ophthalmic Referee under the Workmen's Compensation Act, for the districts of the County Courts in Circuit No. 1 and the districts in part of Circuit No. 2 (Northumberland and Durham). Applications should reach the Private Secretary, Home Office, Whitehall, London, S.W., not later than August 16th.

CASUALTIES AT SHEFFIELD ROYAL HOSPITAL.—The casualties dealt with at this institution during the first half of the present year numbered 11,156, an increase of 659 over the corresponding period of 1929. Traffic accidents numbered 574, of which 231 were caused by motor cars and 190 by motor-cycles.

ADDRESSES AND ORIGINAL ARTICLES

SYPHILIS OF THE HEART AND GREAT VESSELS.

By Carey F. Coombs, M.D., F.R.C.P. Lond.,
PHYSICIAN, AND IN CHARGE OF THE UNIVERSITY CENTRE OF CARDIAC RESEARCH, GENERAL HOSPITAL, BRISTOL.

LECTURE II.*

In my first lecture the share of organic disease of the heart and great vessels to be ascribed to syphilis was assessed at 5 to 15 per cent., and reasons were given for believing that this is a direct relationship; the more syphilis, the more aortic disease. For this reason, males more often show signs of cardiac syphilis than do females. There is usually a latent period of 20 to 25 years between the primary infection and the onset of cardiac symptoms. In this, cardiac syphilis resembles neurosyphilis. Different aspects of cardiac disease were reviewed in their relation to syphilitic infection, with results that I have for convenience arranged in Table IV.:—

TABLE IV.

Forms of cardiovascular disease.	Percentage caused by syphilis.
Aortic aneurysm—	
Thoracic ,,	75
Abdominal ,,	35
Aortic regurgitation	30
Cardiac pain (transient)	15
Cardiac infarction	1–3
Ventricular failure	20
Heart-block	10
Auricular failure	2

To-day we have to construct from a series of case-notes a composite picture of cardio-aortic syphilis as the clinical observer sees it. In a majority of the 103 cases whose records are under review, the *symptoms* that brought the patients to seek advice were cardiac. In a minority other lesions—cerebral thrombosis, tabes, and so forth—stamped them as syphilitic, and this led to an investigation of the cardiovascular system, with the result that physical signs in these few cases preceded symptoms. For the most part, however, symptoms came first and signs lagged behind. I recollect one remarkable exception to this rule in the case of a man of 47, the master of a small vessel, who went to get his life insurance policy increased when he came ashore. To his surprise and indignation this application was rejected on the score of heart disease. Refusing to believe this, he consulted his doctor, who referred him to me for confirmation of a diagnosis of aortic regurgitation. Unmistakable signs were found and, as his Wassermann reaction was positive, we gave him a course of treatment with iodide of potassium, mercury, and novarsenobenzol. He went back to his vessel, still free from symptoms and openly sceptical about his cardiac lesion; but a few days later he failed to come on deck one morning, and was found dead in his bunk. This sequence is exceptional. The rule is that the patient feels something amiss, the principal symptoms of onset being dyspnœa on exertion and præcordial pain; he goes to his medical man and is found to present signs of heart disease. The three great cardiac symptoms—dyspnœa, pain, and œdema—appear in that order, both in sequence and frequency. Dyspnœa, noted in 85 instances, is an early symptom; so is pain, complained of by 58 patients; but œdema, together with other signs of ventricular failure, is only seen later. It was recorded in 43 of my 103 cases. The paroxysmal dyspnœa noted by Keefer and Resnik and other observers has been seen in several of my patients, and my experience tallies with theirs in that this symptom has been much more frequent in syphilitic than in rheumatic lesions of the aortic valves. I should have said, however—though I have not subjected this to the test of statistics—that these paroxysms of dyspnœa are seen even more often in persons with ventricular defeat ensuing on long-continued hyperpiesis. This clinical fact—the occurrence of periodic dyspnœa in these two conditions, hyperpiesis and cardio-aortic syphilis—seems to me a striking exemplification of Fraser's proposition that the chief factor in the production of cardiac dyspnœa is a failure in the delivery of blood to the periphery and therefore to the medulla; for it is in these two kinds of heart disease that the left ventricle is most signally defeated.

Pain in the præcordium was a prominent symptom in 58 cases—i.e., in more than half. There are two or three points worthy of note about it. First, it seems to me that the "angina of decubitus" as contrasted with "the angina of effort" is relatively common in cardiac syphilis; commoner, that is, than in hyperpietic and decrescent syndromes. A good example of this was seen lately in the case of a man of 40, recently under my care in the hospital.

He was admitted under a diagnosis of pneumonia, on the score of dullness with other appropriate signs in the left upper chest. This resolved very unwillingly, and as it did so he developed pain in the right shoulder and across the chest. It was of the characteristic pressing or squeezing type and made him pale and anxious, and although it was aggravated by movement it arose and continued during rest in bed. The triple rhythm so characteristic of serious injury to the ventricular wall was heard for several days, the pulse became alternating, and there was some œdema of the back. His reaction to the Wassermann test was strongly positive, and his progress under the appropriate treatment happily confirmed the diagnosis.

In this case also another feature of the cardiac pain of syphilis—its tendency to an atypical distribution—was exemplified. In one respect, however, the case was unusual, since there was a suspicion of the infarction syndrome about it. The points essential to a confident diagnosis of cardiac infarction appear to me to be, first, a period of severe and persistent præcordial pain; and, second, the addition of new physical signs indicative of change in the texture of the cardiac wall. This syndrome has only once in my experience been seen in an unmistakable guise in this group of 103 cases of cardiac syphilis. This contrasts strikingly with its relatively high incidence in cardiosclerosis of the senile or decrescent type—15·1 per cent. of a group of over 300 cases. Let me make it clear; in cardiac syphilis pain without immediate sequelæ is commoner, while symptoms of the kind that accompany cardiac infarction are much rarer, than in the degenerative types of myocardial disease.

Physical Signs.

The signs may conveniently be grouped under three headings: the aorta and other great vessels, the cardiac valves, and the muscular wall of the heart. I have been a little surprised to find that I only noted ten examples of *aortic aneurysm*—one of them

* The second Lumleian Lecture, 1930. Lect. I. appeared last week.

abdominal, the rest thoracic—among these 103 patients. My impression is that one sees fewer cases of thoracic aneurysm than formerly, but the Registrar-General's returns, though they show some remarkable fluctuations in the annual death-rate from aneurysm, furnish no clear evidence of a decline.

Since the subject of intrathoracic aneurysm was recently expounded here by the late Dr. de Havilland Hall,[23] I propose to say no more on its clinical features but to pass on to a word or two about non-aneurysmal dilatation of the aorta. This I noted in 32 other cases, but I feel sure that this figure is too low, and that if it had been possible to subject all my private patients, as all my hospital patients are subjected, to skiagraphy, it would have been a good deal higher. Increase in the width of the aortic dullness, or of its shadow, or both, is of particular value in the diagnosis of those difficult cases in which there are no signs of valvular or myocardial disease to explain symptoms of cardiac insufficiency. An interesting paper by Beretervide[5] furnishes examples of the application of skiagraphy to the diagnosis of aortitis in congenital syphilis. Detection of a widened aorta is, however, not essential to a diagnosis of cardiac syphilis. Recently we had in the wards a man who had complained of substernal pain ever since a car had knocked him down and broken some ribs. This pain was increased by exertion, he was easily made breathless, and his pulse pressure was low, but there were no physical signs beyond a moderate accentuation of the second sound to the right of the sternum, and his aortic shadow was not widened. Nevertheless, the Wassermann test was definitely positive. In this instance we noted that highly characteristic sign, accentuation of the aortic second sound. It is usually of a lower tone than that which is heard in hyperpiesis, and when it is noted in the appropriate context, and in a person whose blood pressure is not raised, it helps to confirm a diagnosis of cardiac syphilis. It is often found in patients with tabes dorsalis and other nervous lesions and may then persist without further development for years. Even so, however, one cannot look at a section of the aortic wall that has been attacked by syphilis without realising that here alone, in a loss of arterial elasticity, the cardiovascular system has suffered a serious impairment of efficiency.

The series includes one example of syphilis of the pulmonary artery, a woman of 39, who exhibited the Ayerza syndrome. That the lesion was syphilitic was proved by the discovery of posterior sclerosis in the cord. This case has been fully reported in a paper by Clarke,[8] Hadfield, Todd, and myself, and is included in an excellent summary of the whole subject recently published by Dorothy Hare[24] and Joan Ross, from whose conclusions I quote a passage which is in accord with my own views. They say:

> "A well-defined group of cases exists in which arterial disease is confined or largely confined to the pulmonary circuit. These cases differ from other cases with arterial lesions in the lesser circuit in that there is no antecedent pulmonary, cardiac, or bronchial lesion. Syphilis is by far the most important ætiological factor in older patients. Primary non-inflammatory sclerosis of unknown ætiology is found in younger patients. In the syphilitic cases the lesions in the intrapulmonary arteries take the form of an obliterative arteritis, usually most severe in the smaller branches and arterioles. This condition leads to a raised blood pressure in the lesser circuit. Dilatation and hypertrophy of the main pulmonary artery follows, with atheroma of the right and left pulmonary arteries and larger branches, whether the latter show inflammatory lesions or not. The right side of the heart becomes greatly dilated and hypertrophied. Clinically the cases are characterised by dyspnœa, cyanosis, and hæmoptysis, and in the later stages by progressive congestive heart failure with a regular pulse."

Three times, in patients with no evidence of aneurysm, I noted inequality of the brachial tensions, but in none was there the gross asymmetry recorded in syphilitic aortitis by Laignel-Lavastine[54] and Vinlich. It is, however, by no means limited to that disease. I have seen several examples i patients with arterial lesions that appear to b degenerative and not infective, and at the preser time there is a man, aged 62, attending my ou patient department, suffering from the angina effort and also from an intermittent limp; his systol brachial pressures are grossly unequal—240 in th one arm, 180 in the other. This man is proved fr from syphilis by every test that we can apply. Lian, Dreyfus, and Puech express the opinion that arterit interfering with the blood-supply to the upper limb is more likely to be syphilitic than a correspondin disorder of the lower limbs. Even so, however, it to be remarked that among the seven cases full reported by them in which a diagnosis of subclavia arteritis was made, only two were proved syphilit in origin. One physical sign which they descrit is a systolic murmur heard on auscultation in th depths of the supraclavicular fossa and separated, b a zone in which no bruit is heard, from the systol murmur usually heard at the base of the hear This subclavian murmur, they say, is not transmitte to the axillary or brachial arteries. In one case und his care in the Tenon Hospital Prof. Lia demonstrated to me this murmur, which was clear heard and separated easily from that at the base the heart.

Signs of some form of *aortic valvular disea* were noted in 63 cases. In 54 this is recorded regurgitation, in two as obstruction, in seven regurgitation with obstruction. The logical mea of discriminating between the two appears to me lie in correlation of sphygmomanometric readin with the auscultatory signs. Take, for example, th case of a man of 56 admitted to the wards on accou of præcordial pain and dyspnœa. The sounds hea at the aortic base were those of obstruction rather tha regurgitation, for the systolic murmur was loud an accompanied by a thrill, while the diastolic murm was at times scarcely audible; yet the minimu arterial pressure was only 50 mm. Hg, with maximum of 125—a disturbance of the norm proportions which would lead me to judge that th valves were guilty rather of incompetence tha of obstruction.

Some observers say that they find the aort diastolic murmur liable in a number of cases to appe and then to disappear, and this inconstancy ascribed to variations in the width of the aortic rin variations which are thought to arise from a weakeni of the aortic wall by disease. I note that Sir Thom Horder remarks that this is contrary to his experienc that the aortic diastolic murmur, when once it com comes to stay. So at all events it has been with m cases, though when the murmur was first heard one or two instances it was very faint and apt to inaudible except under favourable conditions. Hord also alluded to the sudden and gross increase in t loudness of the murmur that occurs when an aor cusp is ruptured, and illustrated this by reference a dramatic example. I had no instance of this my series, but examination of the aortic cusps in t syphilitic heart affords ample evidence of the likeliho of this disaster. The perforations that Corrig figured and described as "reticulations" are oft seen at the commissural ends of the cusps, and m perhaps be ascribed to the concurrence of two facto —tightening of the base of the cusp with starvati of its tissues.

A mitral systolic murmur was noted 24 times in n patients; in 14 it accompanied signs of a lesion of t aortic valves and in 10 it occurred alone. In the 10, as well as in the others, it seemed to me probab that the incompetence was muscular and not valvula a belief that was verified post mortem in the case a man who had a mitral systolic murmur througho the three years during which he was under observatio His mitral valves were normal, but the auricu ventricular channel was widely stretched. In o other case, that to which I have already alluded discussing lesions of the pulmonary artery, a diasto murmur was heard to the left of the sternum. T

patient was very blue and distressed and I thought the murmur indicated mitral stenosis, but was puzzled because the rhythm of the heart was normal. She died the next day and the pulmonary origin of the murmur was then disclosed.

The fact that this murmur was heard to the left of the sternum reminds me of a statement made some years ago by Hoppe-Seyler, to the effect that in aortic incompetence of syphilitic origin the diastolic bruit is heard loudest to the right of the sternum, whereas in leakage caused by rheumatic endocarditis the diastolic murmur is best heard to the left of the sternum. I believe that this rule is broadly true and agree with the explanation offered—namely, that whereas the syphilitic lesion of the valves is usually accompanied by a dilatation of the aorta which conducts the vibrations up to the chest wall at the second right interspace, that of rheumatism is not thus complicated, and the vibrations are, therefore, heard best in the neighbourhood of the valves themselves, to the left of the sternum.

Interference with the *muscular functions* of the heart is a prominent feature of cardiac syphilis. It is because the disease has this faculty that it is so dangerous. The means by which it effects these injuries must be debated when we come to survey the morbid anatomy; to this, however, an analysis of the modes of myocardial disturbance will serve as an introduction. The total arrhythmia of auricular fibrillation was observed in eight cases, and in addition to this there were two verified and one probable example of flutter. This is rather a high proportion of auricular disturbances. Juster[80] and Pardee noted three examples in 50 cases. In Vela's[54] series of 105 cases examined electrocardiographically there were six examples of fibrillation. In my series there was no obvious difference, otherwise, between the hearts that fibrillated and those that did not. In five of the eight the aortic valves were leaking—a proportion almost exactly the same as that observed in the series as a whole.

Interference with conduction of the stimulus from auricles to ventricles was observed in six instances, three of these being examples of block of the main bundle varying in degree from time to time. Of the others, one displayed the electrocardiogram of a lesion of the right main branch of the bundle, while in the other two the auriculo-ventricular interval was lengthened. This last group would perhaps have been much larger if electrocardiograms had been taken in all cases, yet Juster and Pardee's 50 cases only yielded two examples of lengthened conduction interval and none of actual block. Of Vela's 105 electrocardiograms from cardiosyphilitics three showed block of the main bundle and two of the right branch.

There were signs of increase in the size of the left ventricle in 80 of the cases. It seems to me useless to pretend to discriminate here between dilatation and hypertrophy, for there is no disease of the heart in which these two aspects of ventricular increase are more often or more inseparably combined. In 20 cases there were signs of the gross form of myocardial inadequacy that has been entitled by Parkinson[41] and Bedford "heart failure with normal rhythm," and by French writers "ventricular failure," a term also used by Herapath[11] and myself in a review of different modes of cardiac breakdown. The principal features of this state are œdema below the waist-line, alternating pulse with narrowing of the pulse pressure in some instances, weakening of the impulse and of the cardiac sounds, with a bruit de galop in some cases. This form of failure is notoriously insidious in its evolution, and the signs enumerated are not discovered until it is already far advanced. Does electrocardiography furnish any earlier hints of its approach? My own experience is too small to furnish a reply to this, but some interesting data have been collected. For example, Dr. J. H. Follows, of Liverpool, in some observations which he was good enough to discuss with me, noted alterations in the QRS and the T parts of the electrocardiogram 40 times in 147 cases of syphilis. It is true that in most cases these alterations were slight, but I believe they are worthy of attention. I have tabulated these (Table V.), together with other electrocardiographic data, including an unpublished series collected by Dr. M. A. Cassidy, of which he has kindly made me free.

TABLE V.—*Electrocardiographic Changes in Cardiac Syphilis.*

Author.	Total cases.	P abnormal.	P–R long.	QRS abnormal.	T abnormal.
Early syphilis:					
Cassidy ..	12	0	0	Low voltage, 3. R aberrant, 1.	0
Follows ..	68	0	0	Low voltage, 2. R aberrant, 5.	8
Turner[53] and White ..	50	No gross abnormality.			
Late syphilis:					
Cassidy ..	28	3 Fib., 1. Flut., 1.	0	Low voltage, 11. R aberrant with abnormal.	T = 8.
Follows ..	73	Flut., 1.	1	Low voltage, 1 R aberrant, 15.	9
Vela ..	105	Fib., 6.	S.bl.3 B.bl.2	7	9
Juster and Pardee ..	50	,, 3	2	20	37
Coombs ..	20	,, 1	2	4	5

Fib. = fibrillation; Flut. = flutter. S.bl. and B.bl. = Simple and branch block.

If any broad generalisation can be made from these widely divergent results it is that unmistakable departure from the normal is seen in an appreciable percentage of the electrocardiograms from cases of late cardiac syphilis. Among these observations we may particularly note that in Juster and Pardee's series the T wave was abnormal in 74 per cent. and of a "coronary" type of aberration in 18 per cent. This last they thought they could correlate, by post-mortem observation, with occlusion of the coronary orifices. I doubt, however, whether the evidence of coronary disease derived from electrocardiography is as valuable in syphilitic infection as in the degenerative lesions of the coronary vessels.

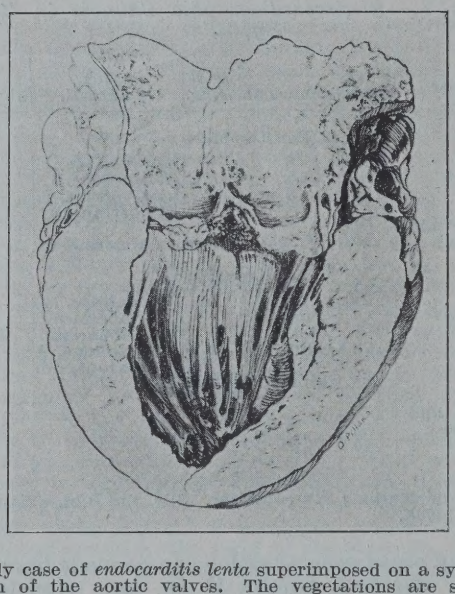
THE CLINICAL PICTURE.

At this point we may pause to summarise and, so to speak, get into focus the clinical picture that has been drawn. What we see is a man just under 50 complaining of shortness of breath and often, also, of pain in the chest, usually excited by exertion, but sometimes also occurring spontaneously. If his symptoms have lasted any length of time there may be œdema about his ankles. Examination of the chest discloses the signs of enlargement of the left ventricle, and the chances are two to one that there will also be those of aortic valvular disease. There is a one in ten chance that he has an aneurysm of his thoracic aorta, and where this is not found there is an even chance that there will be some evidence of aortic dilatation. The cardiac rhythm is likely to be normal, but there is approximately one chance in ten that either a total arrhythmia or an alternating pulse will be noted. His electrocardiogram may show some drag in auriculo-ventricular or in trans-ventricular conduction, or an aberration of ventricular response such as we associate with coronary lesions. On inquiry he may furnish a history of syphilitic infection sustained twenty odd years ago; or his Wassermann reaction may be positive; or he may display other evidence of old syphilitic infection.

In my series of 103 patients these evidences of *other syphilitic lesions* were noted 26 times. The manifestation seen most often was tabes dorsalis, of which there were ten examples; add to this two and possibly three cases of general paralysis and three of internal ophthalmoplegia, and the tale of late parenchymatous syphilis mounts up to 16

cases. Focal lesions of cord and brain were noted two and three times respectively; there was one example of nerve deafness, one of optic atrophy, one of iritis, and two of choroiditis. Chronic glossitis was

FIG. 1.



An early case of *endocarditis lenta* superimposed on a syphilitic lesion of the aortic valves. The vegetations are seen to occupy the commissural ends of the cusps.

noted five times. This seems to me to fall within the same class, clinically and perhaps pathologically, with aortitis and tabes. Gummatous lesions of bone, liver, larynx, and scalp were found in nine cases. Two of the patients had syphilitic children and in three instances repeated miscarriage appeared attributable to a similar cause. I have seen no example of conjugal aortitis such as is recorded by Marañon.

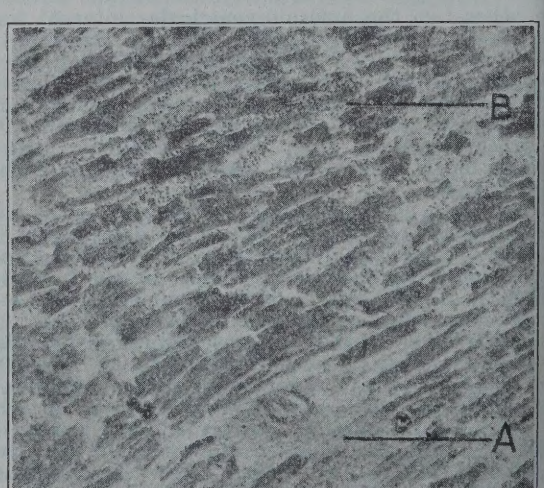
Certain other morbid associations are worthy of consideration here. These are more truly described as concomitants than as precursors. That the progress of cardio-aortic syphilis itself is not greatly furthered by them is, I think, proved by the fact that in *congenital syphilis* the aortic lesion appears at the end of a latent period no longer than that observed in the corresponding and exactly similar lesion of the acquired infection. In fact, the congenital infection often injures the aorta in an appreciably shorter time than that taken by the acquired variety, as I pointed out in the first lecture. It is true that this is not always so. The only two cases that I am able to quote from Bristol experience behaved in this respect as acquired syphilis does. The first case is one that was recorded in 1911 by Prof. J. A. Nixon, that of a young woman who died in the Bristol Royal Infirmary at the age of 20, after a few months of symptoms due to an abdominal aneurysm which ruptured behind the peritoneum. She had Hutchinsonian teeth and changes in the wall of the aorta of a syphilitic character. The second patient was also a young woman, aged 25, who was admitted to the Bristol General Hospital under my colleague Dr. Newman Neild, to whom, and to Prof. Geoffrey Hadfield, then pathologist to the hospital, I am indebted for notes. These show that when admitted she had Hutchinsonian teeth and was in fact treated as syphilitic from the second day after admission. Her symptoms were cerebral and became rapidly worse, killing her in a few days in spite of an operation for decompression. She had a gummatous infiltration at the base of the brain, and an aortitis of which Prof. Hadfield says that it is the cleanest and purest specimen of syphilitic aortitis that he has seen. The coincidence with an atheromatous change is not infrequent, and is very confusing to the morbid anatomist. In neither of these cases do I think there can be doubt either of the existence of an aortitis or of the syphilitic basis of that lesion. So far as the two examples quoted are concerned, the case for a belief in aortititis due to congenital syphilis seems to me complete. Sometimes this is slow in its evolution, as in another case related to me by Prof. Nixon. Here a maiden lady died at the age of 48 of thoracic aneurysm; there was as little doubt that her father had acquired a syphilitic infection as that she herself had not. On the whole, however, there is a larger proportion of early cases among the congenital than among the acquired syphilitics. For instance, there are the cases reported by Cummer[17] and Dexter, by Anderson,[4] and by Worster-Drought[60] and Danvers-Atkinson, wherein the ages at death were 5, 10, and 13 respectively.

Concomitants of Cardio-aortic Syphilis.

From such facts as these it seems probable that the virus can, unaided, bring about serious changes in the aorta within a period of less than 20 years, and that it is not necessary to invoke any *x* factor or factors as essential to the development of a syphilitic aortitis. On the other hand, it is, I think, quite clear that certain other agencies which are often convicted of an attack on the cardiovascular apparatus do from time to time conspire with the syphilitic virus in such a way as to hasten the downfall of those structures and functions which they attack simultaneously. It is not the syphilitic process itself so much as its consequences that they aid and accelerate. I am thinking particularly of four such agents—decrescent or atheromatous arterial disease, hyperpiesis, alcoholism, and diabetes. To this list may be added one other example, that of acute rheumatism.

The part played by atheromatous or senile *arteriosclerosis* I had always vaguely suspected; it is obvious that when these changes overtake a man they are going to make more difference to him, or at all events

FIG. 2.



Section of myocardium from a case of *endocarditis lenta* superimposed on a basis of cardiac syphilis. (A) replacement fibrosis due to syphilis; (B) polymorphonuclear leucocytosis caused by infected embolus from inflamed valve.

are going to be felt more quickly, if the elastic tissue of his aortic wall is already disintegrated by syphilis. But it was not until I had seen, in more than one of the hearts examined histologically, how syphilis and atheroma supplement each other that I understood how neatly and effectively these two destroyers

ork together. It is not merely that in the wall of he aorta itself they overlap; here we may truly ssign the leading part to syphilis, which attacks nd injures the media in a way that the purely degenerative process is incapable of doing. It is not here, however, so much as in the coronary arteries that the dovetailing of these two morbid agencies is seen, for in the coronary vessels themselves it is atheroma that does the damage, the syphilitic lesion limiting itself to their orifices. In sections of many coronary trunks I did not once discover an infective arteritis, and in the twigs only once I discovered it; even when the ortic lesion was severe it always stopped short at ie coronary openings.

FIG. 3.

ection of wall of left auricle, showing small granuloma beneath epicardium.

The relation with *high arterial tension* is perhaps : the same kind, though some observers think it oes deeper. In my own series I met with 15 patients ho exhibited a systolic blood pressure of 200 mm. Hg r more. One might well dismiss this as due to nothing iore significant than the fact that both aortic yphilis and raised arterial tension are diseases of iiddle-aged males, were it not for the arguments dduced by some writers, French physicians in articular, on behalf of a closer relation. Lian, for xample, gave me some figures which show that in 9 per cent. of 291 persons with high tension the Vassermann test yielded a positive result.

Diabetes was discovered by Mitchell Bruce [6] to be a requent accompaniment of syphilitic disease of the irculatory organs. I have not encountered a single xample. Marañon [39] noted it 23 times in 140 cases f aortic syphilis, and insists on the importance of emembering this association whenever a patient ith diabetes is being examined.

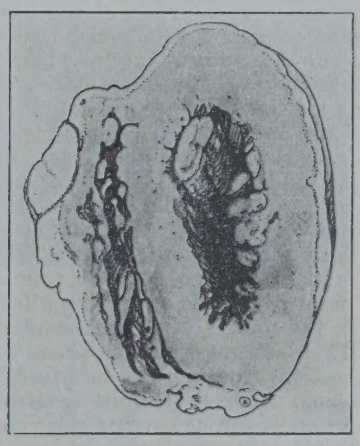
Alcoholic excess was recorded in 16 of my cases. he actual proportion is probably higher than this, ut there is no proof of any causal relation—no proof, hat is, of anything in the effects of alcoholic excess hat favours the course of the syphilitic process. Yet can scarcely be doubted of any of these three agents—yperpiesis, alcohol, diabetes—that it is a powerful ally f syphilis in the reduction of the cardiac efficiency; the rst, by increasing the load to be borne; the second, by s deleterious action on the myocardial cells; and the ast, by ruining the nutrition of the arterial walls.

The effect of *acute rheumatism* on the syphilitic eart may be glanced at in passing. Some years ago saw an interesting example of this. A man about 0, with old-standing aortic incompetence, syphilitic n origin, was attacked by acute rheumatism with ericarditis and quickly succumbed. There are everal examples of this deadly association in the terature (von Glahn [56] and Wilshusen, Cabot [7]). t seems also as if congenital syphilis predisposes o severity in an intercurrent rheumatic carditis; t all events the two are sometimes associated, as in the case related in the first lecture, that of the congenital syphilitic girl, who displayed signs of mitral stenosis before the age of ten (see also Stolkind [48] and Fordyce [21]). On the other hand, the supervention of a syphilitic lesion on a rheumatic basis does not seem to be so serious.

One other disease that is associated with cardio-aortic syphilis owes that association to a different kind of nexus. *Endocarditis* is superimposed on the syphilitic picture in the same way and for the same reason that it is even more often superimposed on that of rheumatic heart disease. It is because the new infection, usually streptococcal, finds it easier to attach itself to a valve that has been made ready for it by some prior injury to its endocardial surface. This relation has been satisfactorily examined by Grant, Wood, and Jones. They say that small platelet thrombi occur with greatest frequency on the valves that are liable to subacute bacterial endocarditis; that this is due to local secondary change in thickened valves; and that in this clot the passing micro-organisms find board and lodging. In my own experience both rheumatic and congenital defects of the valvular surface furnish these opportunities of endocardial infection more often than does syphilis, which has not been identified as a predisposing cause in more than 5 per cent. of my cases of endocarditis. This figure is far below that given by some writers, for instance, Sumbal, [49] who found a positive Wassermann reaction in 18 of 52 cases of endocarditis lenta. Among these 103 cardiosyphilitic patients of mine there were four who were found to have contracted an endocarditis superimposed on the syphilitic lesion (Figs. 1 and 2). The general behaviour of these cases is that of a slow endocarditis of the kind that is usually thought to be due to an alimentary streptococcus. In one of them it was clear that treatment with novarsenobenzol did good, but chiefly in the direction of suppressing the secondary infection, since fever and embolic symptoms disappeared while the liability to præcordial pain and the signs of aortic insufficiency persisted, and the patient died within a year after leaving the hospital.

These few remarks on the morbid influences that may supplement that of syphilis in its attack on the heart may be summarised by saying that atheroma, alcoholism, and diabetes act simultaneously with syphilis in lowering the vitality of the cardiac muscle; while streptococcal infection of the endocardium, itself in these cases a sequela of the syphilitic process, involves the patient in new perils, those of toxæmia and of embolism, while at the same time adding to the cardiac burden by accelerating the valvular failure.

FIG. 4.



(Not referred to in text.) Transverse section of heart showing calcified gumma beneath epicardium of right ventricle.

We are now brought to that point at which clinical investigation can carry us no further in elucidating the nature of the syphilitic attack on the heart. We have seen that in these 103 cases the damage was freely assigned to the aorta, the aortic valves,

and the cardiac muscle; facts that appear clearly in the following table, wherein are assembled some of the data that our clinical survey has yielded.

TABLE VI.

Total cases	103
Aneurysm, thoracic	9
,, abdominal	1
Aortic dilatation	32
Aortic valvular disease	63
Pulmonary dilatation	1
Cardiac pain (transient)	57
Cardiac infarction	1
Ventricular enlargement	80
Ventricular failure	20
Heart-block	3–6
Auricular failure	8–11

It now remains to see whether we can learn from the minute anatomy of these lesions how they are related to each other, and whence they come. The histological data that I propose to embody in the next lecture are derived from a study of 21 hearts, most of which have been subjected to a thorough examination—an examination, that is, of a dozen or more blocks, and of ten or more sections from each block. Three of these hearts were found in the course of that examination to furnish evidence of atheromatous, but not of syphilitic, change. This result deserves to be remembered when it is claimed that the naked-eye appearance of the lesion is a better criterion of its syphilitic origin than clinical evidence can furnish; for in all three hearts the changes resembled those of syphilis and were thought to be syphilitic by experienced observers. In another instance I was inclined to write the heart off as degenerative only and not infected, when I found, in the eighty-sixth section examined, a small granuloma beneath the epicardium covering the left auricle (Fig. 3). This prompted a fresh examination of the aorta, and the characteristic adventitial lesion was found. I ought perhaps to add that in none of the three pseudo-syphilitic cases was there any good clinical ground available for a diagnosis of syphilis; though the Wassermann reaction was strongly positive in a fourth case, that of a man of 67 who died suddenly in a surgical ward, and whose heart presented histological changes as like those of atheroma as of syphilis. Here I accept the verdict of the blood test and interpret the case as one in which the syphilitic attack had ended, leaving ravages which, with the help of the atheromatous process, sufficed to kill the man.

I was stimulated to examine these hearts because I did not find in the literature a completely satisfying answer to several questions. In the first place, why do syphilitic patients so often complain of cardiac pain yet so seldom die of cardiac infarction? Secondly, exactly how does syphilis prepare the endocardial surface for superimposed infections? Thirdly, how is the long gap between primary infection and the onset of cardiac symptoms filled in? Fourthly, what is the nature of the myocardial lesions of syphilis? This last question was prompted by examination of sections from a heart described by C. E. K. Herapath taken from a syphilitic patient with a progressive lesion of auriculo-ventricular conduction in which he found a destruction of the bundle of His so complete, and at the same time so selective, as to remind one irresistibly of system degenerations in the cord.

BIRKENHEAD AND WIRRAL CHILDREN'S HOSPITAL.—Mrs. Paget, wife of the Bishop of Chester, recently opened a new out-patients' department which has cost £15,000. The waiting-hall has been named after the late Mr. W. F. Rogers, of Wallasey, whose bequest provided a third of the cost; the laboratory has been given by Mr. and Mrs. Holttum in memory of their son.

DISTRIBUTION OF RADIATION FROM CLINICAL RADIUM TUBES.

ILLUSTRATED BY PHOTOGRAPHY.

BY S. RUSS, D.Sc.,

PROFESSOR OF PHYSICS IN THE UNIVERSITY OF LONDON, AT THE MIDDLESEX HOSPITAL;

AND

DOROTHY F. CLEPHAN.

(*From the Barnato-Joel Laboratories, the Middlesex Hospital.*)

THE series of photographic tests on radium tube which is the subject of this paper was begun with the idea of obtaining some kind of picture of the distribution of the radiation from tubes arranged in certain simple geometrical patterns.

In cases of malignant disease, the treatment is planned with a view to giving a dose of radiation which does not fall below the necessary minimum for all parts of the growth. The laying out and spacing of the tubes is a matter for careful consideration, and it is generally assumed that the distribution of the radium contained in the tubes is more or less uniform throughout their internal lumen. Auto-photographic pictures are useful in pointing out those parts of the field where inequalities occur in the intensity of radiation resulting from any particular plan. Those illustrated here refer to plans such as might be used for the introduction of radium tubes into breast tumour.

Two schemes were adopted for the photographs illustrated: (*a*) in which the tubes were arranged like spokes in a wheel, and (*b*) in which they were in parallel lines. In Fig. 1, A_1 and A_2 are auto-photographs with the photographic plate parallel to the plane of the tubes at a distance of 7 mm. Schemes A_1 and A_2 were combined, the planes of the tubes being 1·4 cm. apart, and the photograph A_3 was obtained by putting the plate halfway between the two. The effect of the irradiation shown on this plate is far from uniform. In a further set of exposures which are not illustrated here, the photographic plane in each case was 2 cm. from the plane of the radium tubes and the irregularities in density were naturally much less. It is interesting to compare the general result of the one scheme, A_3, with that of the other B_3.

The series B_1, B_2, and B_3 (Fig. 2) was carried out with the photographic plate 7 mm. from the radium tubes, arranged in parallel formation; B_3 is a combination of B_1 and B_2.

Inequalities in Radium Tubes.

Inspection of these photographs shows that the concentration of radium inside the individual tubes is not always uniform. Photographic tests on individual tubes have shown that in some cases it can safely be said that the inequalities in strength of radium along the lumen of the tubes are such as to militate against their proper therapeutic use. For purposes of comparison, an exposure was made of 12 6 cm. radon needles arranged as in scheme A and photograph A_4 (Fig. 3) shows the equality of distribution typical of radon containers.

A few samples of auto-photographs of individual tubes are reproduced in Fig. 4. The drawing on the top left hand side is a scale drawing of the tubes. A is a 6 cm. tube filled with radon; B, C, and D are

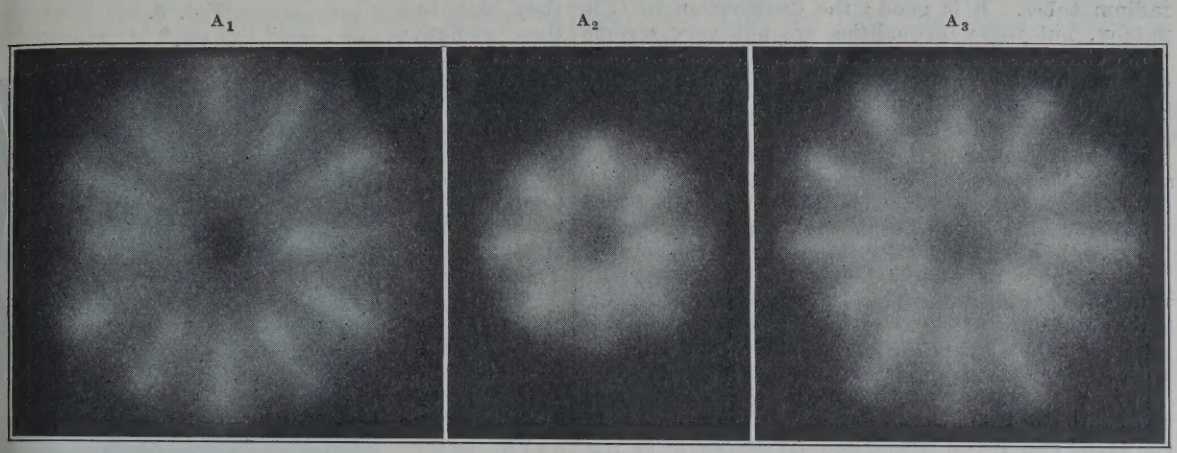


FIG. 1.

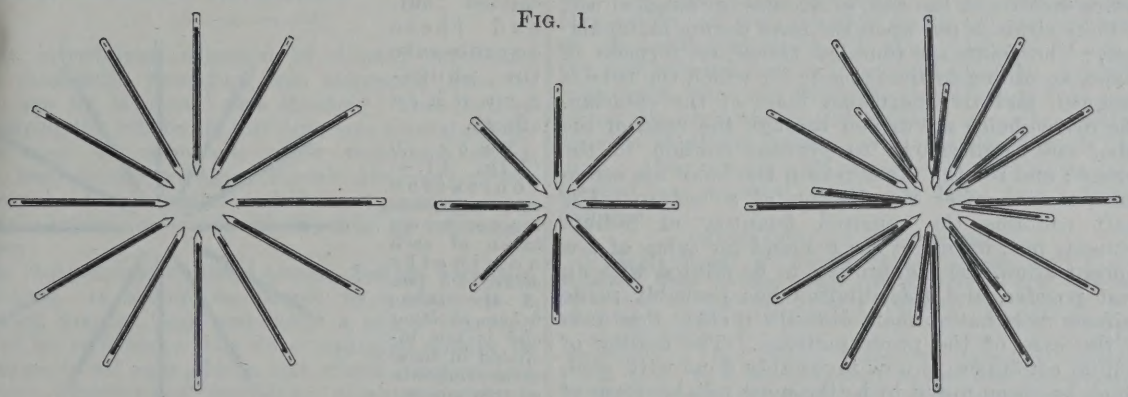

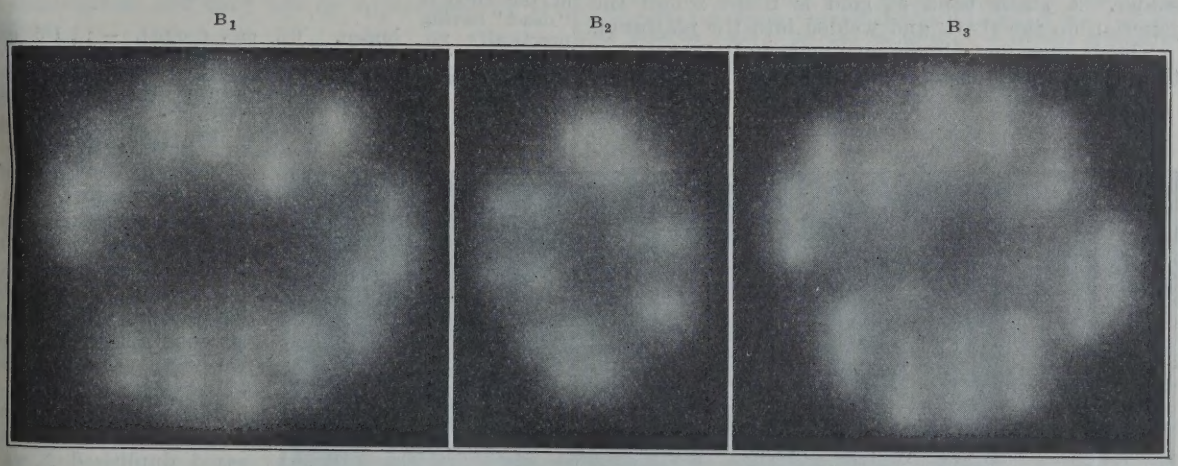

FIG. 2.

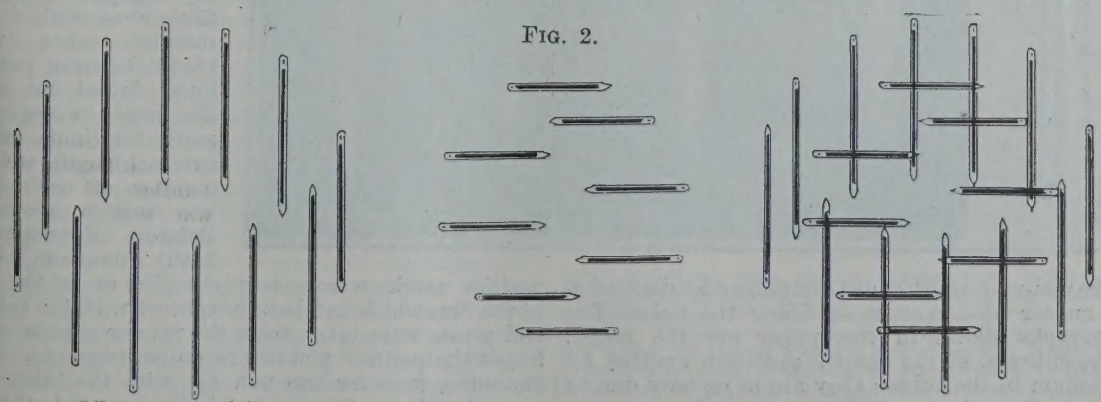

radium tubes. B is good; the distribution in C is patchy, but these inequalities are not very serious when the radiation effects at one or two centimetres distance are being considered. C is a badly filled tube, nearly two centimetres out of the six being practically devoid of radium.

The construction of the platinum radium tubes and so-called "needles" is well known, but will, perhaps, bear repetition here. The terms "tube" and "needle" are used somewhat indiscriminately, "needle" being generally applied to the sharp-pointed tubes of narrow lumen and small content which are designed particularly for surgical insertion. Tubes and needles are at present constructed in two parts—a hollow cylindrical shaft, and a separate part with a plug end made either to screw into the shaft or to fit it exactly. The separate part is sometimes the point and sometimes the head end. Filling from the point end of the tube might be judged to be the better method in the case of needles for surgical use, as more strain is put upon the head during manipulation. The points are rounded, trocar, or torpedo in shape, according to the purpose for which the tube is designed, and the individual taste of the clinician. The eyelet holes are drilled through the head of the tube, and countersunk to prevent friction to the thread; and for the same reason the holes are sometimes slotted after the fashion of a bodkin. The shaft contains the required quantity of radium element, but, owing to the demand for tubes of low concentration, the radium has to be diluted with an inert powder, and this dilution has probably made uniform distribution more difficult to effect than it is in the case of the purer material. The sealing of radium containers is now invariably done with gold, which has been found to be the most reliable form of solder. A small band of gold is fitted round the junction on the shaft, and welded into the platinum.

The stopper and plug at one end, and the point at the other, make some "dead space" inevitable; they due to the radium salt shifting about inside the tube. The exposures of the photographs have been such as to bring out clearly any irregularities in filling.

Ionisation measurements of different sections of certain tubes have been carried out, and these corroborate the photographic effects.

Tube D (Fig. 4).—Ionisation measurements have been taken of each nominally active 1·5 cm. of the tube; 0·7 cm. at either end is not included in these measurements as this amount of the tube is "dead" having practically no lumen. 0·7 cm. (point), —; 1·5 cm (next to point), 13 per cent.; 1·5 cm. (middle o tube), 47 per cent.; 1·5 cm. (next to eyelet end), 40 pe cent.; 0·7 cm. (eyele end), —.

FIG. 3.

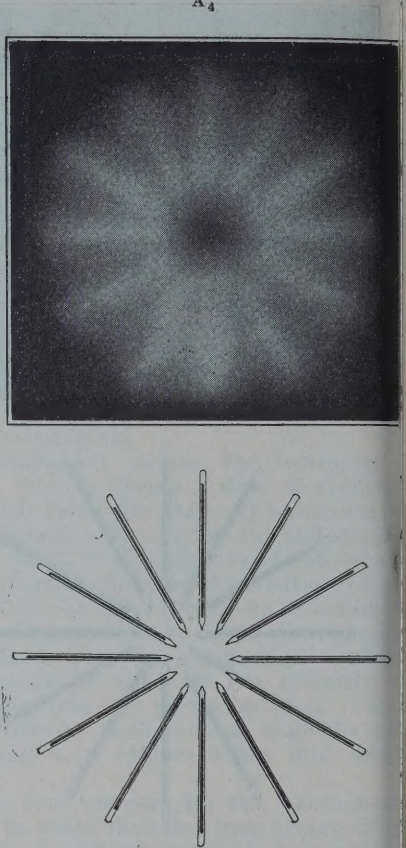

FIG. 4.

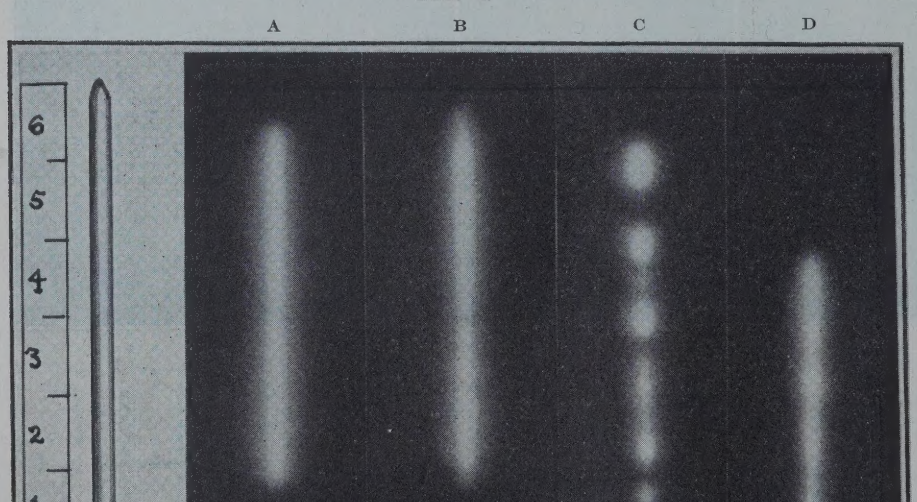

Method of Test.

Radium centres may wish to reassure themselves about their own radium tubes. Photographic tests are comparatively simple to carry out, but a brief account of the method we have used may be of service.

For the individual tubes ¼-plate special rapid duplitised X ray films were used. The radium tubes were placed between parallel lines plotted out upon the paper wrapper to mark the limits of the external length, and the number of each tube was written above it. Before development both numbers and position marks were carefully copied on to the side of the film which had been in contact with the tubes and prints were taken from the reverse side in order to get the positive pictures in proper sequence. The exposures were for two minutes, with the tubes laid upon the films. The geometrically arranged schemes

but the non-uniformity of distribution under discussion is a matter of technique in filling the tubes. The photographs shown in this paper are the result, almost entirely, of the gamma radiation emitted by the radium in the tubes; they are in no way due to contamination of the outside of the tubes, nor are

A and B were taken upon X ray plates at the distances specified in the text, the exposures being 15 minutes. Development of films and plates was carried out with Metol Hydroquinine developer at a temperature of about 18° C., for five minutes in all cases. A standard exposure and development was also given for the prints.

Purchasers of radium may find it necessary in the future to insist upon guarantees relating to the distribution of the radium in tubes, as well as certificates of purity and quantity.

THE INTRADERMAL TUBERCULIN TEST.

By James Maxwell, M.D., M.R.C.P. Lond.,

ASSISTANT PHYSICIAN, ROYAL CHEST HOSPITAL, LONDON; LATE JUNIOR ROSE RESEARCH FELLOW, ST. BARTHOLOMEW'S HOSPITAL.

The intradermal injection of diluted tuberculin as a diagnostic procedure was suggested over 20 years ago by Mantoux[1] and Mendel.[2] This method of applying the tuberculin test possesses several advantages over the numerous other variations which have been employed since Koch's discovery of the properties of tuberculin, and it is becoming more widely adopted, especially in the field of veterinary surgery.

The ideal skin test should possess certain essential attributes. It should be simple to perform in a standard manner, and preferably a single injection should be sufficient; the dose employed should be the same in all cases, for a test which involves two or more injections of increasing doses at intervals is cumbersome and may not be appreciated by the patient.

The result should be easy to interpret and must not be harmful to the patient, either on account of the size of the local response or owing to severe general reaction. In addition, the result should convey some clear indication of disease or of its absence; a test which yields positive reactions in a large proportion of healthy adults is of little assistance in clinical diagnosis. The intradermal tuberculin reaction is clearly capable of fulfilling some of these requirements when employed under favourable conditions; in each case an exact quantity of tuberculin can be injected with certainty into the deeper layers of the skin so that the resultant reactions in a series of cases are strictly comparable, and the extent and significance of the reaction can be assessed with a considerable degree of certainty. It remains to consider whether the results have a definite diagnostic value and whether the reactions are likely to prove in any way harmful.

During the past two years I have been engaged upon a clinical investigation of lymphadenoma at St. Bartholomew's Hospital under the direction of the Rose Lymphadenoma Research Committee.

Some observers have considered that lymphadenoma is really an atypical variety of tuberculosis affecting chiefly the lymphatic glands, and, although the evidence in support of this view is not convincing, it was thought desirable to test a series of patients suffering from this disease by means of the tuberculin reaction, in order to obtain further evidence for or against the theory. After some preliminary comparison of the merits of the various possible methods, the intradermal method was selected for its simplicity. In addition to cases of lymphadenoma, tests were performed on cases of proved tuberculosis and cases apparently quite free from tuberculous infection, in order to control the results obtained in the series under observation. The object of this paper is to place on record a satisfactory method of performing the test, together with a discussion of the results.

Technique.

In performing the test, the following essentials must be kept in mind. In the first place the quantity of material injected must be sufficient to give positive reactions where such reactions should occur, yet it should not be so great as ever to cause severe reactions. The diluted tuberculin is apt to deteriorate, and for this reason it is preferable that the dilutions should be freshly prepared before use. Lyle Cummins[3] gives three weeks as the maximum length of time after which the diluted fluid should not be used, but in the present series the diluted tuberculin was never kept for more than 48 hours, thus ensuring the elimination of any possible factor of deterioration in the standardisation of the reactions. Lastly, the site selected for the injection should be carefully considered, not only from the point of view of ease of injection but also in order that a strongly positive reaction shall not interfere with the functions of the limb. After considerable preliminary work a standard method was evolved which has since been rigidly followed.

PREPARATION OF THE MATERIAL.

A single batch of Koch's old tuberculin (O.T.) was obtained from Messrs. Allen and Hanburys, and this has been used throughout. When required, 0·1 c.cm. of this material is diluted with sterile normal saline solution to a concentration of 1 part in 1000 of fluid. Each cubic centimetre of the diluted tuberculin therefore contains 1 mg. O.T. It is not necessary to add any preservative if the dilution is always carried out shortly before the injection is made; indeed, in a test of this nature it is unwise to introduce any foreign material which might of itself cause the skin to react. At the same time a similar quantity of the control solution, supplied by the same firm, is diluted in exactly the same way, and two tuberculin syringes with ordinary intradermal needles are sterilised by boiling. This procedure naturally produces some degree of blunting of the points of the needles, but as far as intradermal work is concerned, this is rather an advantage, as the points are less likely to slip through the skin into the subcutaneous tissues, a mishap particularly to be avoided in performing the test.

INJECTION INTO THE PATIENT.

The dose eventually selected as the best and consequently standardised was 0·1 c.cm. of the 1 in 1000 dilution, equivalent to 0·1 mg. O.T. Greater doses were injected in some of the earlier cases, but the resultant reactions were apt to be unduly severe, while lesser doses were frequently found to produce equivocal responses. The most suitable site for the injection is the palmar surface of the forearm, midway between the elbow and the wrist. It is accessible and the skin is fairly thick and easily immobilised. Injection of tuberculin in the region of the elbow-joint should be avoided. Occasionally quite severe reactions were obtained even with 0·1 mg. O.T., but in no case was any inconvenience caused to a patient. The control solution should be injected at least 2 in. on the proximal side of the tuberculin injection. This procedure must always be carried out; in two cases out of the 374 recorded here, a false positive reaction occurred.

Both materials are injected into the deeper part of the skin, raising a small wheal which disappears within half an hour. Care must be taken to avoid leakage of tuberculin into the subcutaneous tissues, as unexpected temperature reactions may develop in tuberculous patients if this should occur. The actual technique of the injection differs in no respect from that of intracutaneous injections in general.

THE REACTION.

The reactions were always examined 48 hours after the injection had been given, as it was found that the maximum change had occurred at this period in the majority of cases. On three occasions, however, a positive reaction was found to appear between the third and sixth days. A positive reaction occurred in two controls, consisting in each of an area of erythema about 1 cm. in diameter.

The tuberculin reaction in one of these cases was precisely similar, and there was no reason to suspect tuberculosis from the clinical examination. In the other case the tuberculin reaction yielded the typical positive result in a case of proven tuberculosis. In the remaining 372 cases the control was entirely negative.

The typical tuberculin reaction possesses two distinct features: in the centre of the lesion there is a pale, round or oval area of swelling, palpable to the finger and frequently tender, and surrounding this there is usually an area of erythema. The relative sizes of these two features vary considerably in different cases. In strongly positive reactions there may also be some local irritation of the skin, but general reactions with rise of temperature were only observed in three cases, in which there was consequently a suspicion that there had been a subcutaneous leakage of tuberculin. Separate notes were taken of the extent of the areas of swelling and erythema. It was found that in some cases they were dissociated, either occuring without the other, and the cases in which this phenomenon was noted were studied further. It was then discovered that whereas a simple erythema without swelling was associated with cases which were either doubtful or apparently non-tuberculous, swelling without erythema, on the few occasions on which it occurred, was almost invariably associated with proven tuberculosis. The importance of this point in reading a reaction is obvious. Attention must be paid only to the area of swelling and erythema alone should be disregarded. As has already been mentioned, the two positive control reactions consisted of an area of erythema only, and thus the essential element of a positive tuberculin reaction was absent. The estimation of the degree of the reaction is rather arbitrary, but an area of swelling less than 1 cm. in diameter is reported as "weak positive"; between 1 and 2 cm. is the usual result and may be classed as "positive." Any reaction in excess of this is rare, but may be classed as "strongly positive."

Results.

The results have been classified in accordance with the clinical conditions. A large number of cases was also tested in which the presence or absence of tuberculosis could not be satisfactorily determined, and these cases have accordingly been excluded from consideration.

Group 1 consists of cases of proven tuberculosis. In all the cases of this group either tubercle bacilli were demonstrated or at least typical giant-cell systems were present in sections. The cases may be further subdivided as follows:—

(1) Chronic pulmonary tuberculosis: of 54 cases tested, 49 yielded positive and 5 negative reactions.

(2) Acute tuberculosis: in this condition the intradermal test is usually negative. There were five cases in this group and one reaction was weak positive, the remaining four being negative. One of these cases was quite instructive. The test was performed on a girl aged 6, who was suspected to be suffering from tuberculous mediastinal glands and the result was positive. Two months later the patient was readmitted with tuberculous meningitis and, on repetition of the test, a negative result was obtained.

(3) Tuberculous infection of lymphatic glands: 15 cases were tested and all gave positive reactions. It was in this group that the most marked reactions were obtained.

(4) Tuberculosis elsewhere in the body: of seven cases tested, six gave positive reactions and one a negative.

The total number of proven cases of chronic tuberculosis tested was therefore 76, and a positive reaction was obtained in 70 cases, equivalent to 92·1 per cent. of the total.

Group 2 consists of cases which were almost certainly tuberculous yet in which the final proof was lacking. In this group are classed cases of pleurisy with effusion, cases diagnosed clinically as tuberculous peritonitis, and a few cases of bone and joint disease. Of the 58 cases tested, 51 gave a positive and 7 a negative reaction.

Group 3 consists of cases in which no evidence of tuberculosis could be found. This group is the most difficult to select, for it is almost impossible to be sure that there is no tuberculous lesion in the body even on careful post-mortem examination. The cases consisted of apparently healthy individuals and cases of malignant disease, bronchiectasis, disease of the blood-forming organs, and other cases in which the presence of tuberculosis could be reasonably excluded. In this control series of 189 cases, 59 yielded positive and 130 negative reactions; it should be noted that the cases in this group were mostly adults. In this series of apparently non-tuberculous cases, therefore, only 31·2 per cent. yielded a positive result.

Group 4 consists of the cases of lymphadenoma which were the main object of the investigation. Forty-two patients were tested, and of these 7 gave positive and 35 negative reactions. In three of the positive cases and one negative case there was evidence of the coexistence of a tuberculous lesion. Apparently, therefore, if any significance is to be attached to the test at all, the tubercle bacillus plays no part in the causation of lymphadenoma.

Four additional cases, not included in the groups considered above, were tested. Each showed X ray evidence of calcification in lymphatic glands which appeared to be presumptive evidence of a healed tuberculosis, and none showed any evidence of activity. In three the reaction was quite negative whereas in one, clinically identical with the others, the reaction was strongly positive.

Discussion and Conclusions.

The object of this paper is to describe a standard technique for the intradermal tuberculin reaction and to consider the diagnostic value of the test. The prognostic significance depends upon a number of complicated factors which cannot be considered here except in so far as they have a bearing on the actual result of the test. In proved chronic tuberculosis the test is usually positive, whereas in apparently non-tuberculous cases the percentage of positive results is considerably smaller. The results of Cummins[3] suggest, however, that where the body is reacting well to the toxin and overcoming the infection, the skin reaction may be weak or even negative, and this is supported by the negative reaction found in cases of apparently healed tuberculosis. It must be understood, however, that the size of the reaction is no sure guide to the activity or otherwise of the lesion and that, on the whole, the more severe cases, whose resistance is broken down, also tend to show little or no reaction. The significance of the delayed reaction is also not clear; it occurred twice in cases of lymphadenoma with no evidence of tuberculosis and once in a case of chronic pulmonary tubercuolsis with apparently good resistance. A positive result does not, of course, prove that the particular disease under investigation is necessarily tuberculous, for there is nothing to prevent a small hidden tuberculous focus coexisting with some more obvious lesion which is non-tuberculous.

The significance of the two elements commonly found in the positive reaction is obscure. It seems probable that the area of swelling is an anaphylactic phenomenon and therefore the result of a previous sensitisation to the toxins of the tubercle bacillus.

The area of erythema is not apparently a specific effect and may possibly be a reaction to the protein derived from the bodies of the tubercle bacilli, as distinct from their toxin; it certainly does not appear to have the same significance as the swelling, and it does not seem impossible that sensitisation should occur to the material of which the tubercle bacillus is composed in the absence of an actual infection by the organism with resultant sensitisation to its toxin. The result of the test, therefore, must be interpreted in conjunction with all the other evidence available. In cases of doubt a positive reaction will be one link in the chain of evidence; a negative reaction is of more value in the exclusion of tuberculosis.

The test by itself, however, does not prove a diagnosis, and failure to realise this fact is responsible for many clinical errors. The test, when employed with proper safeguards, may yield information of value if performed in suitable cases; its indiscriminate use as a mainstay in diagnosis is to be condemned.

In conclusion, I wish to express my thanks to the medical staff of St. Bartholomew's Hospital for their permission to perform the test upon the cases under their care, as well as for the great interest which they have evinced in the results obtained.

CONTROLLED RECESSION OPERATION

FOR THE TREATMENT OF CONVERGENT STRABISMUS.

By P. Eldon Gorst, M.D. Liverp.,

ON. SURGEON TO ST. PAUL'S EYE HOSPITAL, LIVERPOOL, AND HON. OPHTHALMIC SURGEON TO BIRKENHEAD GENERAL HOSPITAL.

Since Dieffenbach in 1829 divided the internal rectus muscle for the correction of internal strabismus, numerous new methods or modifications have been advocated and indicate the dissatisfaction of ophthalmologists with the available operative techniques. These surgical procedures consist briefly of either tenotomy, a tendon lengthening, or a recession of the internal rectus muscle and a shortening, advancement, or tendon folding of the external rectus muscle, while any of the procedures on the internal muscle may be combined with any on the external muscle.

With any of these operations it is usually easy to put the eyes straight on the operating table, but there is a very definite element of uncertainty as to the ultimate result. It is, however, possible to form a very accurate estimate of the final result of the operation at the end of the first week, when the tendons have adhered to their new sites and the muscles have commenced to adapt themselves to the new conditions of balance. At this time:—

(1) If the eyes are still convergent they will probably: (*a*) remain so if there is full adduction; (*b*) go straight if there is moderate adduction; or (*c*) diverge if adduction is almost absent.

(2) If the eyes are straight they will probably: (*a*) remain so if there is full adduction; or (*b*) diverge if there is poor adduction.

(3) If the eyes are divergent this condition will probably increase, especially if the adduction is defective.

The fear of producing a paralytic divergence, owing to failure of the divided rectus to reattach itself to the globe, has made common the practice of under-correction on the operating table. In the operation I am about to describe, paralytic divergence is, for practical purposes, an impossibility, and it is easy to make secondary adjustments at the end of the first week—i.e., at the time when one is best able to judge what the final result will be.

The Operation.

After anæsthesia has been induced by drops of cocaine and adrenalin and a small injection of novocain and adrenalin at the site of the operation, a speculum is inserted and the patient is requested to abduct the eye. The conjunctiva over the insertion of the internal rectus muscle is picked up with fixation forceps, a vertical incision about 1 cm. long is made, and the conjunctiva is undermined as far as the inner canthus. Tenon's capsule is next opened at the upper and lower borders of the tendon and a strabismus hook passed beneath the tendon. The tendon and the anterior part of the muscle are defined by blunt dissection. A double-armed suture of No. 2 black braided silk is now taken and the needles are passed through the tendon from within outwards, as shown in Fig. 1. The needles are introduced about 3 mm. from the insertion of the muscle, and each takes a bite of about one-third of the breadth of the tendon. (It is usually quicker to use one needle only for this portion of the operation, going first from without in, then across the front of the tendon, and then from within out.)

Fig 1.

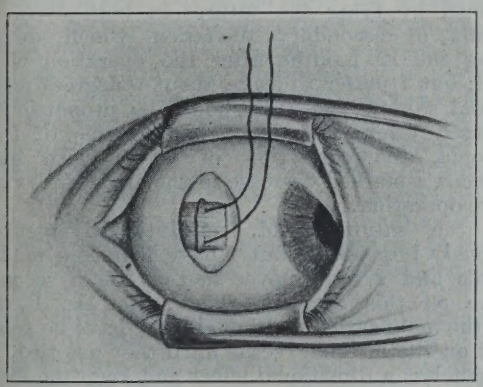

Fig. 2.

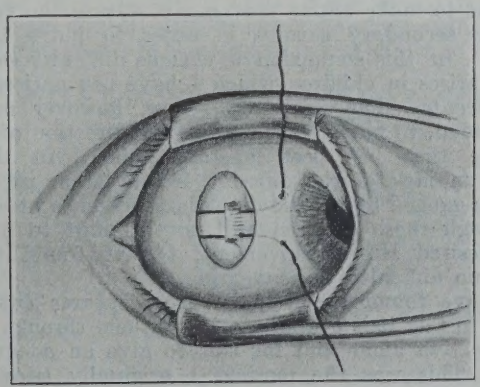

The hook is now withdrawn; the tendon is held forward by drawing on the sutures, and with a few snips of the scissors is divided about 1 mm. from the globe. The sutures are held by an assistant and a search is made for the lateral insertions, which are divided. The two ends of the suture are now passed through the episcleral tissue beneath the

insertion of the divided tendon and, slightly diverging, are brought out through the conjunctiva close to the limbus (Fig. 2). The conjunctival wound is carefully closed with two or three sutures of No. 0 silk. The long ends of the sutures are tied together, wrapped round a piece of lint, and fixed to the forehead with strapping.

The eye is lightly closed with a pad and strapping during the first 24 hours, but after that the dressings are removed during the day, though a pad is strapped on during sleep to prevent accidental pulling on the sutures. The eye should be irrigated every two or three hours during the day, and mild antiseptic drops, such as colloidal silver, should be instilled, while neoprotosil ointment is freely inserted before sleep. If rigid care is taken to ensure cleanliness by repeated dressings there is very little conjunctival reaction.

Between the fifth and seventh days the case is carefully considered. If the eyes are straight or have about 5 degrees of residual internal squint and there is good adduction, the sutures are removed; but if the eyes are divergent or if there is poor adduction the sutures are tied, the procedure being as follows.

The eye is anæsthetised with cocaine and adrenalin drops and a pledget of cotton-wool soaked in the solution is placed on the globe over the site of the operation and left, or renewed, until the hyperæmic conjunctiva is blanched. While the anæsthetic is acting the sutures are unravelled and cleaned by painting them with weak iodine. When anæsthesia is complete, the small sutures uniting the conjunctival wound are removed and the first double turn of a surgical knot is tied on the main sutures. This knot is gradually tightened, the effect being noticed between each tightening until the desired effect is produced, when the knot is completed. This suture should be removed at the end of a further five days. When both eyes have been operated upon, the secondary suture is, of course, first tied on the eye which possesses the poorest adduction.

The operation presents no difficulties, and can be performed on comparatively young children (from 10 years upwards) with only those difficulties inseparably connected with their varying temperaments. It is not a suitable operation to perform under general anæsthesia, as it is necessary for the patient to make active movements during the tying of the secondary sutures in order to judge their effect. In this connexion a curious difficulty sometimes arises in children which I have not noticed in adolescents. Some children refuse, however much persuaded, to move their eyes in the direction of the muscle that has been operated upon. In these cases an idea of the amount of adduction present can be gauged by the amount of convergence present. Although these children will not attempt to make the desired lateral movement, I have found they have no difficulty in converging.

I have found no difficulty from sutures cutting out; in fact it is possible to insert them through the conjunctiva alone and for this to give an adequate hold. This was the method I originally adopted, inserting the sutures after the method of the Richard Williams advancement operation. I found that at the end of a week the conjunctiva was so firmly adherent that it completely failed to come down and left the suture in direct contact with the cornea; this method had therefore to be abandoned.

The operation can be combined with any operation on the external rectus of the same eye if the tenotomy alone is insufficient to correct the squint, but I much prefer to repeat the operation on the second eye. If the entire correction of a high degree of internal squint is to be borne by one eye only, the new insertion of the internal rectus must be so far back that poor adduction and divergence are likely to ensue. With this operation it is the diliberate policy moderately to over-correct the squint upon the operating table. If the squint is 15 degrees to 18 degrees or under, an operation on one eye will usually suffice, but if the squint is over 18 degrees it will be necessary to operate on both eyes. The complete division of both internal recti will over-correct most internal squints.

A difficulty arises in moderate squints which are under-corrected by a single tenotomy and heavily over-corrected by a double tenotomy. I find the best method with these cases is to do the full operation on one eye and to allow a moderate recession of the other internal rectus. This can easily be brought about by immediately tying the suture of one eye. The suture is tied in the way already described, the first turn of the surgical knot being tightened until only the desired amount of over-correction is present, when the knot is completed.

The Secondary Sutures.

When the sutures are tied on the seventh day the maximum amount of secondary correction obtainable cannot be definitely stated, but I think it is from 7 degrees to 10 degrees in each eye. I find it is usual for a slightly greater correction to be manifest on the day after tying the secondary suture than when the patient is on the table. While it is possible to obtain a correction of this amount on the seventh day, a much greater amount can be obtained by tying the secondary suture on the fifth day. In young patients—that is to say, from 10 to 16 years old—it is safer to tie the secondary suture on the fifth day if there is much over-correction present. In these cases union between the divided tendon and the globe often takes place more rapidly than in older patients, and I have once or twice been disappointed in the amount of secondary correction that I have been able to obtain. This, however, was before I adopted the practice of immediately tying the main suture if marked over-correction followed the tenotomy. In one case, which was inadvertently left for two weeks, no result was obtained by tying the sutures in both eyes. The amount of secondary deviation which develops during the 12 months after the operation is very slight, but I prefer to leave about 5 degrees residual internal squint, and this should be proportionately increased where there is a high degree of hypermetropia, the correction of which with glasses produced a marked decrease in the angle of deviation before operation.

If the sutures hold, paralytic divergence is obviously impossible, but I have found no tendency to this and I have never had to tie a secondary suture on this account. The reason is, I think, that the main sutures, although they have no traction effect on the internal rectus until they are tied, have nevertheless a directional effect and keep the divided tendon applied to the globe. None of the cases I have yet operated upon have shown any tendency to divergence, but that a small percentage will do so seems inevitable when we remember that it is not uncommon for internal squints to straighten themselves even after 20 years of age, and sometimes even to go on to divergence without operative interference.

It is obvious that those cases which become straight naturally would have become divergent whatever operation had been undertaken. It seems

absurd deliberately to under-correct at the first operation with the intention of probably doing a second operation of a similar nature at a later date, when it is no more difficult to readvance a well-united internal rectus, if subsequent divergence should make this necessary. If the internal rectus is well united and there is good adduction, this should only be necessary in that very small percentage of cases that would have become straight without operation.

Paralytic divergence, through failure of the divided rectus to reunite with the globe, is of course a very different matter, owing to the great difficulty of correcting it by operation; it must be regarded as a surgical disaster.

The most, I think, that we can expect of any squint operation is that in every case it will enable us fully to correct the strabismus and yet leave the eyes with a practically full range of mobility. I have performed this operation on 126 cases and, with the exceptions mentioned, have always been able to obtain this result.

THE CAUSES OF DEATH AMONGST DIABETICS.

By D. M. Lyon, M.D., F.R.C.P. Edin.,

PROFESSOR OF THERAPEUTICS AND CLINICAL MEDICINE IN THE UNIVERSITY OF EDINBURGH;

AND

R. M. Murray Lyon, M.D., M.R.C.P. Edin.,

CLINICAL TUTOR, ROYAL INFIRMARY; PHYSICIAN, NEW TOWN DISPENSARY, EDINBURGH.

With the introduction of modern methods of dietary control and the use of insulin for suitable cases, the outlook of the diabetic has been totally changed. It is sometimes said that under efficient treatment the prognosis is so improved that the patient's expectation of life is as good as that of a normal individual. For the majority of diabetics this may be so, but the occasional occurrence of unexpected deaths raises the question of how far the general statement is true. It is too early yet to answer the question from national statistics [4] for, as has been pointed out, improved treatment will enable many sufferers to live longer. The incidence of diabetes is stated to be increasing, but this increase may be more apparent than real, and may in part be due to the increased interest which has been directed to the subject in the last few years. It has been suggested that a proportion of diabetic deaths are avoidable and should not occur under modern conditions.[1] The present investigation has been undertaken to examine the question and to find out the dangers which face the diabetic.[5]

The deaths reported in this paper are taken from a clinic of about 2000 cases of diabetes mellitus. For several reasons it is not possible to work out a death-rate for these cases. An attempt is made to keep in touch with all diabetics who have been seen in the clinic in order to ensure that they remain sugar-free at all times, and so to prevent recurrence of symptoms or the development of complications. It is hoped also that information of prognostic value may be collected in this way. In spite of this follow-up service, and even with the help of an efficient social service department, it is difficult to keep track of all the patients. Some go off diet, feel comparatively well for a time, and return later with their original symptoms fully developed. Others cannot be traced; undoubtedly a number of these have died. Such elements of uncertainty make statistical investigation difficult. Sufficient information on the causes of death has been collected for 150 cases, and an analysis of this material is presented below. A few of the patients died in hospital within a short time of admission. About half were in-patients for a time, and the others were only seen at the clinic as out-patients. The majority of deaths occurred at the patients' homes or in some other institution.

Effect of Age, Sex, and Habit.

A superficial survey of the causes of death shows that they may be grouped as follows: (*a*) cardio-vascular conditions, 43 (28·7 per cent.); (*b*) infections, 37 (24·7 per cent.); (*c*) improper treatment, 21 (14·0 per cent.); (*d*) cancer, 13 (8·7 per cent.); (*e*) tuberculosis, 11 (7·3 per cent.); (*f*) acute non-surgical abdominal conditions, 9 (6 per cent.); (*g*) miscellaneous, 16 (10·6 per cent). Coma in itself is not to be regarded as a primary cause of death but rather as a contributory complication. Fifty-nine cases (39·3 per cent.) developed acidosis and died in coma; the majority did not show this symptom.

The *age* at death ranged from 8 to 74, 68 per cent. of the cases being over 45 years of age. The return of the Registrar-General for 1927 shows that in Scotland 81·2 per cent. of diabetics who died were over 45, as compared with 63·3 per cent. of deaths from other causes. Joslin [2] has found the same thing in his cases, and points out that diabetes is very largely a disease of advanced life; indeed, the average age at death of his latest group of diabetics is actually three years later than that of the average citizen in the same district.[3] A striking feature in our series is the remarkably small number of young cases, only 14 being under the age of 25. This is probably accounted for by the readiness with which young patients respond to treatment by insulin. The age at death appears to have a considerable influence on the question of whether coma will occur or not. For our whole series the average age at death was 50·5 years, while for the coma cases it was 37·4 years, as compared with 59 years for those who did not develop coma. As will be seen in Table II., the average age of death in some of the non-coma groups is considerably higher. Of the 48 cases under 45 years of age, 38 developed coma (64·4 per cent.), while of the 81 patients over this age only 21 died in coma (35·6 per cent.). The influence of age in this respect is well shown in Table I.

Table I.—*Percentage of Deaths due to Coma at Different Age-periods.*

Age-period.	Total deaths.	Coma: deaths and percentage.	Age-period.	Total deaths.	Coma: deaths and percentage.
0–14	2	2 (100·0)	55–64	35	7 (19·4)
15–24	12	11 (91·6)	65–74	35	2 (5·7)
25–34	18	13 (72·2)	75+	5	0
35–44	16	12 (75·0)			
45–54	26	12 (46·2)		150	59 (39·3)

It will be seen that in earlier years practically all cases developed coma before death, while in later life this tendency diminishes and finally disappears. The danger of developing coma is inversely proportional to the age of the patient. A similar observation has been made by Joslin.[1]

Sex.—The series shows a preponderance of females, 86 (57·3 per cent.), to 64 males (42·7 per cent.), a ratio similar to that found in the national statistics (66·9 per cent. to 33·1 per cent.). The excess of females is greater amongst the patients over middle life, and especially amongst those dying of cardio-vascular conditions. The same phenomenon is shown

by the statistics for Greater London quoted by Joslin.[2] The coma cases are practically equally divided—29 males to 30 females.

Habit.—The habit of body during the period of treatment is also of importance in relation to the development of coma. Nineteen cases (12·7 per cent.), 17 of whom were women, were recorded as obese; none of these developed coma. This fact is in keeping with the clinical observations that the fat diabetic only rarely shows acetone in the urine, even when on a low calorie diet. From the nature of the disease it is probable that many of the 54 patients of normal weight had previously been obese. The 77 thin individuals included 39 males and 38 females. Coma developed more frequently (64·4 per cent.) amongst those who were under weight.

Duration and Treatment.

Duration of Disease.—Joslin [1] has suggested that nearly all diabetics who die in the first year of their disease die of coma, and has put this forward as good proof that coma is avoidable. Elsewhere [3] he suggests that diabetes is milder the longer it lasts, though in this statement there is an obvious fallacy. Our figures show that of 54 cases of under two years' duration 51·8 per cent., of 68 between two and five years 35·3 per cent., and of 26 who had had diabetes for more than five years 19·2 per cent. developed coma. the duration of adequate treatment appears to be of little importance.

Type of Treatment.—It is to be expected that the more severe cases requiring insulin would show a higher percentage of deaths and of coma before death, but the matter is complicated by the number of deaths amongst mild diabetics of advanced years. Insulin as well as dietary restriction was required by 72·7 per cent. of all subjects, and the proportions are practically identical in both coma and non-coma cases. On the other hand, the faithfulness of the patient in carrying out instructions is of the greatest importance. In 57 of the patients dietary control was unsatisfactory for some time before death; 20 of these cases were under 45 years, and all except one, who was aged 40, developed coma (95 per cent.), while of those over middle age 12 out of 37 suffered from coma (32·4 per cent.). Improper dieting appears to be very serious for the young but of less consequence among the aged.

Causes of Death.

The cardiovascular group is the largest; no patient in this section was under 45 years and the average age of death was high. Fifteen of these patients died from cerebral hæmorrhage, 11 from heart failure following arterio-sclerosis, and 8 after gangrene. The heart failure cases include only two in which the cardiac disease was of long standing. The common factor in this group is vascular degeneration, which was also prominent amongst the other non-coma cases. In a series of post-mortems on 51 diabetic subjects, Wilder [7] reports a high incidence of arterio-sclerosis (71·4 per cent.) and of renal damage. Joslin [3] points out that, as the occurrence of fatal coma is reduced by improved treatment, there is a steady increase of cardiovascular and renal deaths.

Malignant disease accounted for 13 deaths and none of these patients showed coma. Cancer of the head of the pancreas was confirmed by post-mortem examination in two cases, and in two others who died jaundiced a similar diagnosis was made. One patient after a long history of atrophic cirrhosis developed a nodular enlargement of the liver, which was diagnosed as a primary cancer. Another patient on whom a post-mortem was performed was found to have a cancer of the pylorus affecting neither the liver nor the pancreas. A diagnosis of cancer of the stomach was made in two cases, and of the colon (one case), and of the uterus (one case), but there was no opportunity for confirming these diagnoses. In addition, there was one example of carcinoma of the tongue, one sarcoma of the jaw, and one cancer of the cervix. Thus in most cases the malignant disease was probably unrelated to the diabetes. It is to be expected, of course, that a group of people of this age-distribution would show a number of deaths from cancer. One individual who died from gangrene also suffered from scirrhus of the breast.

Sepsis of various kinds, other than gangrene, is given as the immediate cause of death in 37 cases (18 males, 19 females), of whom 20 developed coma before death (54 per cent.). The importance of age in relation to this question is shown by the following figures. Under 35 years of age, 90 per cent. of the septic cases developed coma; between 35 and 65 the proportions are about equal (coma in 55·6 per cent.); while in 9 cases over that age coma was absent.

Phthisis (ten cases) and Pott's disease (one case) caused 7·3 per cent. of the deaths. It is interesting to note that the average age of death in this group was 55·4 years, and that only one of these cases was below 40, although tuberculosis used to be considered the scourge of the young diabetic. Coma was absent in this group. Miscellaneous causes of non-coma deaths include pernicious anæmia (two cases); peptic ulcer with fatal hæmatemesis (two cases); hæmochromatosis (one case); and accident (one case).

Breaking diet, inability to take food, or failure of the insulin supply, led directly to 21 deaths from diabetic coma (13 males, 8 females). Nine of these patients were over 45.

TABLE II.—*150 Diabetic Deaths.*

A. Non-coma Deaths (91).

Cause of death.	Cases.	Percentage of all deaths	Average age.
Senility	8	5·3	73·4
Gangrene	8	5·3	66·0
Arterio-sclerosis and heart failure	11	7·3	63·7*
Cerebral hæmorrhage	15	10·0	61·8
Chronic nephritis	1	0·7	57·0
All cardiovascular	43	28·6	65·1
Respiratory infections	9	6·0	59·5†
Acute abdominal sepsis	4	2·7	59·5‡
Septicæmia	2	1·3	70·0
Erysipelas	1	0·7	38·0
Cellulitis	1	0·7	26·0
All sepsis (non-coma)	17	11·4	57·5
Tuberculosis	11	7·3	55·4
Malignant disease	13	8·7	59·5
Pernicious anæmia	2	1·3	43·0
Peptic ulcer—hæmatemesis	2	1·3	36·5§
Acromegaly	1	0·7	62·0¶
Hæmochromatosis	1	0·7	27·0
Accident	1	0·7	30·0
Total non-coma	91	60·7	59·0

B. Coma Deaths (59).

Breaking diet	21	14·0	38·4
Gastro-intestinal upset	9	6·0	36·9
Focal sepsis	7	13·3	36·0
Respiratory infections	13		40·7
Hæmatemesis	1	0·7	25
Unspecified coma	8	5·3	32·7
Total coma	59	39·3	37·4
All deaths	150	100	50·5

* 1 myxœdema. † 1 with parotitis; 1 acromegaly.
‡ 2 appendicitis; 2 peritonitis. § 1 with carbuncle.
¶ 1 also died of influenza.

Deaths from coma followed non-surgical *gastro-intestinal upset* in nine cases. In all but one of these the preceding treatment had been entirely satisfactory. The fatal illness in these cases came on suddenly and was of short duration. It was characterised by nausea and persistent vomiting, usually accompanied b

ntense abdominal pain and sometimes by diarrhœa. Symptoms of this sort may occur as the result of ketosis in diabetes, but in these cases we believe that the gastro-enteritis preceded the onset of the coma. In a further group of eight cases coma is given as the cause of death without mention of any precipitating factor.

Amongst the 150 fatal cases there were a number in which other ductless glands were involved besides the pancreas. There were two cases of acromegaly (aged 53 and 62) and one of myxœdema (aged 59), none of whom developed coma. Four patients who also suffered from hyperthyroidism appear amongst the deaths from coma, two as the result of respiratory infections, one from breaking diet, and one not specified. They were aged 30, 35, 37, and 40.

Discussion.

Diabetes mellitus should be regarded as a symptom-complex rather than as a single disease, since it is probable that it may be produced by several different pathological processes. The figures just examined suggest that a diagnosis of "diabetes" covers at least two distinct conditions, an impression which has also been formed in the clinic. The two types may almost be distinguished by the age of onset of the symptoms. The young cases often give a history of some immediately preceding infective process, with a rapid development of symptoms. The initial disturbance may be considerable and the disease appear severe, yet under satisfactory conditions a good deal of recovery is often possible. Although favourable when properly managed, these cases require careful supervision in order to avoid trouble. It is essential for them to follow a strict régime, for the dangers of relaxation of effort are greater in them than in diabetics over middle life. Sepsis, gastro-intestinal upset, and major errors of dieting, all tending to development of acidosis, are the dangers especially to be feared. Acetonuria and coma are readily produced in this type of case, but should be absent under adequate treatment or, where developed, should be controlled by insulin, death being thereby avoided. In this "toxic" type the patients may be somewhat under weight, but are usually otherwise healthy. Degenerative processes are absent and there is no history of obesity. The sex-incidence is about equal in patients under the age of 45 (26 males, 22 females), as we have already shown in the thin subjects and those dying of coma.

The second group of diabetics is distinguished from the first in several ways. As a whole, the patients are older; indeed, many might be regarded as long-lived. The diabetes of later life has long been recognised as mild in type and little liable to the complications found in younger cases. Usually it appears insidiously, the first sign being gangrene, eye trouble, or pruritus. The progress of the disease is slow and there is little tendency to acidosis. Amongst the outstanding features of this group are the prevalence of arterio-sclerosis, the occurrence of obesity, and the preponderance of females. The grossly overweight individual is commonly regarded as a potential diabetic,[3] [6] and it may be that the metabolic disturbance which leads to obesity is closely related to that in diabetes. This form of obesity is more common in women and leads to high blood pressure and often to arterial damage. The high incidence of arterio-sclerosis in diabetes is usually regarded as evidence that it depends on the metabolic disturbance, but it is equally possible that the relationship is just the reverse. From a study of this type of diabetes it is our impression that the insidiously progressive vascular disease occurs first and leads to pancreatic degeneration in much the same way as it affects the kidneys. The mildness of this type may in some degree be due to the slower development of the lesion and to a gradual adjustment of the body to the altered conditions. Patients who suffer from this "degenerative" type of diabetes do not die from coma but from some other cause, often vascular. Like the other group, however, these patients also show a lowered resistance to infections, and under the influence of these the diabetes may become more prominent.

It will be observed that amongst the non-coma deaths there are a few who do not conform to the "degenerative" type. These include the patients who died of erysipelas (aged 38), cellulitis (26), hæmatemesis (29 and 44), one pernicious anæmia (29), the accident case (30), and possibly also the hæmochromatosis (27). In some of these cases death probably occurred too rapidly to allow the development of coma. When allowance is made for these cases, the average age of death of the non-coma patients is raised from 59·0 to 62·1 years.

Summary.

An analysis has been made of the cause of death in 150 cases of diabetes mellitus. Coma preceded death in 59 of the cases, being precipitated by sepsis, abdominal upset, or by faulty treatment. Deaths without coma were mainly due to cardiovascular lesions, to sepsis, to tuberculosis, and to malignant disease not necessarily involving the pancreas. The investigation suggests that the cases of diabetes may be grouped into two classes: (*a*) the "toxic" type in younger individuals with a tendency to develop coma; (*b*) a "degenerative" type, characterised by greater age, arterio-sclerosis, and a tendency to obesity. Treatment should be rigidly followed by all subjects under middle age in order to avoid the danger of acidosis. This danger is of lesser importance for the older diabetic, but in his case attention should be specially directed to the vascular system.

GLASGOW WESTERN INFIRMARY.—It is reported that upon a total expenditure last year of £90,783 there was a surplus of £3634. The average stay of each patient (12,521) was 18·18 days; in 1928 it was 20·05. In the David Elder Infirmary it was 19·96. The average cost per patient was £6 14*s.* 8*d.*, as compared with £7 18*s.* 3*d.* in the previous year. It is still impossible to proceed with the ophthalmic department, for which the money is in hand, in consequence of the continuance of the Rent Restrictions Act, the site being occupied by tenement houses belonging to the infirmary. The new X ray and electrical department, a section of which will be set apart for radium treatment, is nearing completion.

PROPOSED EXTENSION OF MOORFIELDS EYE HOSPITAL.—It has long been desired to enlarge the out-patient department of the London Ophthalmic Hospital, City-road, E.C., but space has been lacking. An opportunity now occurs of purchasing the adjoining cocoa factory, which would not only provide the means of extending this department, which deals with an average of 480 patients daily, but would afford additional scope for the post-graduate school, larger laboratories, the extension of research facilities, and a larger physico-therapeutic department. The purchase price of the factory is £4000, towards which £1200 is available, and the Lord Mayor, the vice-president, and Mr. T. W. Luling, the chairman, are appealing for the balance.

CLINICAL AND LABORATORY NOTES

INTERSTITIAL PREGNANCY IN A TUBAL STUMP

AFTER SALPINGO-OÖPHORECTOMY.

BY L. AYLWIN RICHARDSON, F.R.C.S. ENG.,
LATE RESIDENT SURGICAL OFFICER TO THE SOUTH DEVON AND EAST CORNWALL HOSPITAL, PLYMOUTH.

Interstitial pregnancy is very rare. Werth, operating on 120 cases of ectopic gestation, saw no example of it, and Munro-Kerr saw one in 80 cases. The Johns Hopkins Clinic puts the incidence at 0·65 per cent. Still more uncommon are cases in which pregnancy occurs in the interstitial part of the tube after salpingo-oöphorectomy. After a survey of the literature at my disposal I can find only seven cases in any way comparable to that described here.

DESCRIPTION OF THE CASE.

The patient started to menstruate at the age of 16. Her periods were regular and painless, occurring every four weeks and lasting five days. Her children were 15, 12, and 4 years old. There had been no miscarriages. Five years ago she was operated upon after the rupture of an ectopic gestation. The right Fallopian tube and ovary were removed and she made an uninterrupted recovery. A year later she was delivered of a full-time child.

The last normal menses occurred five weeks before admission to hospital. A week before the patient had noticed a blood-stained discharge per vaginam, lasting only a few hours. The onset of this corresponded with the expected time of her period. For the last 14 days the patient had been aware of an uneasy dragging pain in her right side but had had no acute pain. At 4 P.M. on the day before admission she felt definite epigastric discomfort and nausea. At 7 P.M. she was seized with sudden right-sided pain of sufficient violence to double her up. She went to bed but the pain was severe throughout the night, during which time she vomited twice. At no time was there any loss per vaginam. Next morning she was sent to hospital by ambulance and arrived at 2 P.M.

On admission her temperature was 99° F., her pulse-rate 88, and her respiration-rate 24. She looked well and appeared comfortable. The mucous membranes were not blanched. The tongue was moist but covered with a white fur. The abdomen moved poorly on respiration but showed no rigidity. Hyperæsthesia was marked in the right iliac fossa. On deep palpation tenderness was elicited just above the mid-point of Poupart's ligament on the right side. On examination per rectum and per vaginam the patient complained of tenderness on the right side. Bimanually the uterus was felt to be slightly enlarged. The breasts showed no signs of activity.

On opening the abdomen at 3 P.M. the pelvis was seen to be full of blood, partly clotted and partly fresh and bright. Bearing in mind the previous operation, the left Fallopian tube was immediately palpated but found to be normal. The incision was extended downwards and the uterus brought into view, the whole organ being slightly enlarged. The fundus on the right side was definitely raised (Ruge Simone's sign).* On the upper aspect of the uterus, about a quarter of an inch internal to the point at which the right tube was originally attached, there was a ragged bleeding cavity about a quarter of an inch in diameter. This was at first thought to have been caused by some instrument used to procure abortion, but on carefully mopping the blood from its walls chorionic villi were plainly seen. An effort was made to pass a probe through the hole into the cavity of the uterus, but no communication could be discovered. A small wedge of adjacent uterine musculature was excised and the resulting wound closed with buried sutures of catgut. A search was made for a remnant of ovarian tissue on that side, but none was found. A small corpus luteum cyst was seen in the left ovary. The wound was closed without drainage and the patient made an uninterrupted recovery.

McIntyre,[3] Campbell,[4] and Douglass[5] report very similar cases, interstitial pregnancy occurring in each case in the tubal stump after removal of both tube and ovary. Lesse,[6] Di Palma,[7] and Hofmeier[8] report cases following removal of the tube alone. The *Journal of Obstetrics and Gynæcology*[9] quotes a case in which there is no statement as to whether or not the ovary had been removed along with the tube at the first operation. Nache[10] reports a very interesting case of interstitial pregnancy occurring three months after he had attempted sterilisation of the patient for pulmonary tuberculosis by removing the Fallopian tube on each side, together with a wedge of uterine tissue. Campbell states that in his case the uterine cavity communicated with the ovarian cavity by means of the orifice of the Fallopian tube. Douglass, on the other hand, tried unsuccessfully to pass a probe from the ruptured ovarian cavity into the uterus.

COMMENTARY.

There were several points in this case which made even the diagnosis of a ruptured ectopic gestation uncertain. The pain, although of sudden onset, was preceded for three hours by epigastric pain. The pain was definitely right-sided—that is, on the side on which tube and ovary had previously been removed. The history of a missed period was a doubtful one, and at no time during the attacks of recent pain had there been any vaginal loss. The absence of this last symptom is noted by McIntyre, Leyland Robinson,[11] Vineberg,[12] and others, but its absence is by no means constant. Moreover the patient showed none of the signs of internal hæmorrhage, her pulse rate, for instance, being only 88.

Rupture occurred in the fifth week, although Curtis[13] and others consider that an interstitial pregnancy tends to rupture about four weeks later than one in the Fallopian tube itself. But Waegeli in his masterly paper, La Grossesse Interstitielle, found that out of 38 collected cases,

4	ruptured	during	the	1st month.
11	,,	,,	,,	2nd ,,
9	,,	,,	,,	3rd ,,
7	,,	,,	,,	4th ,,
7	,,	after.		

The age at which rupture occurs seems to depend solely upon the site of implantation of the ovum. If this takes place at either end of the interstitial portion of the tube, rupture will be early; if in the central part, where it will be surrounded by thick muscle, rupture will be late. The assumption in this case is that implantation was at the extreme tubal end.

Waegeli argues at length the question as to whether an interstitial pregnancy develops within the lumen of the tube or in the uterine muscle deep to the mucous membrane. Were growth intracanalicular we should expect, in each case, to find that the ovarian cavity communicated by means of the uterine opening of the Fallopian tube. In those cases in which ovarian and uterine cavities have been found to communicate, Waegeli considers that there has been a rupture of the muscular septum between them rather than a dilatation of the uterine opening of the tube. His microscopical findings support this contention, for in one case he traced the lumen of the interstitial part of the tube and found it complete and separate from the ovarian cavity throughout its length. He concludes that when implantation occurs in the interstitial part of the tube, where the

* Ruge Simone's sign consists in its entirety in noting that with an interstitial pregnancy (1) the fundus on the affected side is raised, (2) asymmetry of the adnexa is present, (3) the round ligament has a lateral insertion into the fœtal sac.

mucous membrane is thin and uncomplicated by folds, the ovum finds itself in direct contact with the uterine musculature, thus differing from uterine implantation where the thick decidua prevents contact with the muscle. It differs, too, from tubal implantation where, owing to the complexity of the folds of the mucous membrane and to a partial decidual reaction, the ovum does not at first come into contact with the muscle itself. On these grounds Waegeli considers that every case of interstitial pregnancy is to be regarded as truly intramural and extracanalicular.

We know nothing of the mechanism of arrest and implantation. In our case there was certainly no ovarian tissue on the right side; therefore the ovum must have come from the opposite side. It may have passed normally down the left Fallopian tube, become fertilised, and entered the uterine orifice of the right tubal stump; this is extremely improbable. It is far more likely that the ovum, originating from the left ovary, crossed the peritoneal cavity and found its way into the right tubal stump, which for some reason had regained its patency. That such regeneration can occur after salpingectomy is proved by the remarkable case reported by Nache.

Again, one can but speculate on the point at which fertilisation occurred. It may have been that the uterine orifice of the right tube had been constricted by previous inflammation so that it would permit the entrance of spermatazoa but not the exit of the fertilised ovum. On the other hand, fertilisation may have taken place either in the interstitial part of the right tube or in the abdominal cavity by spermatazoa which have found their way up the left Fallopian tube. Blacker[15] points out that this is the normal procedure in pregnancy in the rudimentary horn of a bicornuate uterus, in which there is no communication with the cavity of the uterus. It is conceivable that if fertilisation had taken place by this method within the abdominal cavity, the ovum would have grown to such an extent as to inhibit its progress down the narrow interstitial part of the tube. In our case there was nothing in the previous history pointing to such pelvic inflammation as might have been responsible for the partial closure of the uterine orifice of the tube. In the reported cases of interstitial pregnancy the previous histories often tell of febrile abortions and other similar inflammatory troubles. In McIntyre's and Di Palma's cases the tube had previously been removed on account of salpingitis. Hennig[16] has suggested that the mouth of the tube is sealed over by an excessive decidual growth, thus preventing the entrance of the ovum into the uterine cavity. Another possible explanation of interstitial pregnancy is that the ovum becomes embedded in one of the tubular diverticuli of the uterine mucosa. Waegeli, although he noted the presence of such diverticuli in one of his sections, was unable to trace any connexion between them and the ovarian cavity.

My thanks are due to Mr. G. C. F. Robinson, senior surgeon to the South Devon and East Cornwall Hospital, Plymouth, for permission to publish this case and for the opportunity of operating upon it.

NON-SPINOUS PSOAS ABSCESS.

FOUR CASES AT A CHILDREN'S HOSPITAL.

BY S. BEHRMAN, B.SC. LOND., M.R.C.S. ENG.,
LATE HOUSE SURGEON TO THE QUEEN'S HOSPITAL FOR CHILDREN, HACKNEY ROAD.

THE type of psoas abscess here considered has no origin in the spine and is not tuberculous. This group of abscesses does not appear to be generally recognised and may therefore present difficulties in diagnosis. The cases reported were admitted to the Queen's Hospital for Children during 1929 and three of them were observed by myself. The cases showed a marked similarity and the first may be taken as typical.

CASE 1.—A boy, aged 4½, was sent to the hospital with the diagnosis of acute appendicitis. Five days previously he had been noticed to be feverish and had vomited once. Two days previously he had begun to limp and had complained of pain in the right groin and the right lower abdomen. When he was admitted the temperature was 101° F. The abdomen moved well; tenderness in the right iliac fossa was marked and some fullness could be detected just above the right Poupart's ligament. The right hip-joint was flexed to nearly 90° and extension was very limited and painful. In this position of flexion other movements of the hip-joint were almost normal. Nothing abnormal could be seen or felt in the spine or loins. Rectal examination showed marked tenderness on the right side. The X ray films of the spine and hips were negative. The urine was sterile.

On the operating-table the hip-joint remained flexed even after the patient was deeply anæsthetised, thereby showing that the flexion was not due to irritation of the psoas muscle. An incision was made above Poupart's ligament and, after the fascia iliaca had been incised extraperitoneally, about a pint of greenish pus escaped. On exploration of the abscess cavity its connexion with the psoas sheath was established (hence the persistent flexion due to the distension of the sheath). The wound was drained and uninterrupted recovery followed, with complete range of movement at the hip-joint.

CASE 2.—A girl, aged 6½, was admitted on July 24th, 1929, suffering from pain in the right hip, which had lasted for four days. She had been unable to walk for two days. On admission her temperature was 102° F. Tenderness was marked in the right iliac fossa and a mass could be felt there. The right hip-joint was flexed to a right angle and extension was painful. There was a nearly healed septic toe on the left foot. X ray films of the spine and hip were negative. A blood count showed 19,000 white cells. The urine was sterile and contained approximately 70 pus cells per c.mm. McBurney's incision was made; the appendix appeared healthy but the psoas was bulging and was incised and drained through the abdominal incision. Staphylococci were grown from the pus and the von Pirquet test was negative.

CASE 3.—A boy, aged 13, was admitted on April 7th, 1929, complaining of aching in the right hip, thigh, and knee for a week. He was unable to walk. On admission his temperature was 102° F. and his right hip was flexed to an angle of 45°. The spine appeared normal. At operation the iliopsoas sheath was exposed extraperitoneally, incised, and drained. Staphylococci were grown from the pus.

CASE 4.—A girl, aged 4½, was admitted on August 4th, 1929. She was limping and constipated and had had pain in the right thigh for six days. On admission her temperature was 101° F. and extension of the right hip was limited and painful. A swelling could be felt in the right iliac fossa and bimanual rectal examination showed that it extended into the pelvis. Leucocytes, 25,000. The urine was sterile, and contained approximately 70 cells per c.mm. The abscess was aspirated and *Staphylococcus aureus* was grown from the pus. No tubercle bacilli were

seen. X rays of the spine and hip were negative and the von Pirquet test was negative.

DIFFERENTIAL DIAGNOSIS.

In none of the cases was the correct diagnosis made before admission to hospital. The presence of a psoas abscess was not recognised in three cases. Case 1 was diagnosed as an acute appendicitis and Case 2 as an appendix abscess. The insidious onset and the absence of marked and progressive signs of peritonitis in spite of continued pyrexia should distinguish acute iliopsoas abscess from acute appendicitis and appendix abscess. The flexion of the hip-joint, which is maintained during anæsthesia, should help further to make this distinction. Case 3 was diagnosed as acute arthritis of the hip, a condition which is characterised by the immobility of the joint. In this case, however, on careful examination it was found that all the movements could be made painlessly if the hip was held in flexion. In Case 4, in which a psoas abscess was recognised, the diagnosis of Pott's disease was made. There was no loss of mobility of the spine when the patient was sitting, and this was an argument for excluding the spine as the seat of disease.

PATHOLOGY.

Staphylococci were grown from the pus of four cases. Only in one case was there an obvious focus of infection—a septic toe. The non-tuberculous nature of these cases is shown by the fact that the von Pirquet reaction was negative in the three cases in which it was performed. In three cases the urine was sterile but its cellular count was definitely raised. If we assume that this high cellular count suggests an infection in the neighbourhood of the kidney—there being nothing to indicate an infection of the urinary tracts—the course of the disease is quite compatible with a lower pole epinephric abscess (Israel[1]) discharging into the iliopsoas sheath. The possibility that the pus may pass downwards behind the fascia iliaca is supported by Wolkow and Delitzin,[2] who have demonstrated that the anterior and posterior sheaths of the renal fascia fail to unite inferiorly. Non-spinous psoas abscess may also originate from either tuberculous or pyogenic lymphadenitis of the retroperitoneal glands, as described by Baer, Bennett, and Nachlas.[3] Also, the rare cases of acute arthritis of the iliosacral joint may give rise to a psoas abscess.

My thanks are due to the surgeons of the Queen's Hospital for Children for permission to publish these cases.

A CASE OF SIMULTANEOUS DIPHTHERITIC AND SYPHILITIC INFECTION OF THE THROAT.

By Hester E. de C. Woodcock, M.B. Leeds,
SENIOR ASSISTANT MEDICAL OFFICER, LEEDS CITY HOSPITALS.

A man of 45 was admitted to the Leeds City Hospital on Nov. 8th, 1929, as a case of diphtheria. Before admission *B. diphtheriæ* had been isolated from the throat and 4000 units of antitoxin had been given. The history was that the patient had had a sore throat for two months. He had felt run down for some time, but had attributed this to a "septic finger," following an injury by a piece of wire in August.

On admission the man looked ill, with a greyish pallor. The temperature was 99° F. and the pulse-rate 102. There was some slight congestion of the fauces, most marked on the right. The tonsils were slightly enlarged, and on the right there was a thick mass of yellow slough filling the tonsillar fossa, with definite excavation of the lower end of the tonsil. There were one or two yellow patches on the posterior pharyngeal wall. The mouth was very offensive. The glands were enlarged and tender at the angles of the jaw, and also in the posterior triangles. The right index-finger had been on wet dressings for many weeks. The nail had been removed, the end of the finger was bulbous and sodden, and there was a little suppuration of the nail bed.

A Schick test could not be performed, owing to the administration of antitoxin before admission. Although the throat lesion was not typically diphtheritic, in view of the bacteriological findings, a further dose of 16,000 units of antitoxin was given on admission, and simple gargles prescribed before further investigations were made. The finger was fomented for a week, and then put on dry dressings. A direct smear from the throat showed only mixed cocci with no suggestion of Vincent's organisms, while *B. diphtheriæ* were again found in culture, and on inoculation into guinea-pigs proved to be virulent. The Wasserman reaction was positive.

On Nov. 13th the patient was put on hyd. c cret. gr. ii t.i.d., and six doses of 0·3 g. of novarsenobenzol were given intravenously at weekly intervals. On Nov. 16th he became very deaf, and on the 18th he began to ramble and became forgetful, but this condition only lasted a few days. On the 19th there were stabbing pains in the lumbar region shooting through the abdomen. On the 20th the throat, until now very resistant to treatment, became much cleaner but the excavation of the right tonsil was still very marked. The finger was by now almost healed. The throat was not absolutely clean until Dec. 10th. For the first three weeks after admission there was an irregular temperature, between 99° and 103° F., with an occasional drop to subnormal, the pulse-rate ranging from 84 to 128.

On Nov. 21st the patient developed a dark pink rash, punctate on the trunk and legs, somewhat papular on the arms and shoulder-blades. The next day it became more vivid, more profuse, and more measly in character, with small areas of white skin between the macules. The voice became hoarse, the throat congested and dry. The next day the rash looked more like a fading scarlatinal eruption, and by Nov. 24th it appeared as a diffuse dark erythem on the trunk, and gradually faded. On the 28th the temperature fell to normal and remained there, with the exception of an occasional rise after the intravenous injections. On Dec. 27th the tonsils were removed, as the throat culture persistently showed the presence of *B. diphtheriæ*. Ten days after the operation, when the fauces were completely healed, the cultures became negative, and the patient was discharged from hospital to the care of his own doctor.

The case is interesting because of the persistent presence of virulent diphtheria organisms in a throat which showed clinically a secondary syphilitic lesion, and because the condition failed to clear up on administration of diphtheria antitoxin. The true nature of the lesion was proved by the Wasserman reaction and by the response to antisyphilitic treatment.

The occurrence and peculiar nature of the rash raised several questions: (*a*) Was it caused by serum? Probably not, in view of its persistence and its changing type. (*b*) Was it an exanthem? Against this were the variability in type, the absence (apart from the congestion of the throat) of any other typical sign or symptom, and the fact that during the whole of his stay in hospital the patient was isolated. (*c*) Was it due to the novarsenobenzol? It occurred after the second dose, but on no other occasion. (*d*) Was it a syphilitic manifestation? This is probably the most likely explanation.

The "septic finger" began four months before admission, and healed shortly after antisyphilitic treatment was started. Could this have been the site of syphilitic infection, as there was no other evidence of primary sore?

I am indebted to Dr. J. S. Anderson, superintendent of the City Hospitals, for permission to publish this case.

REVIEWS AND NOTICES OF BOOKS

Malformations of the Jaws and Teeth.

By Dr. EMIL HERBST, Honorary Lecturer and Principal of the Orthodontic Division, Wilhelm's University, Westphalia; and Dr. MAX APFFELSTAEDT, Professor and Director of the Dental Institute of the University. London: Humphrey Milford, Oxford University Press. 1930. Pp. 320. 25*s*.

MALFORMATIONS of the teeth and jaws considered as a branch of antenatal pathology concern the anatomist, teratologist, and dental surgeon. They represent a fascinating chapter in the curious aberrations to which the human embryo is subject.

The first part dealing with malformations of the jaws is from the pen of Dr. Herbst. This section will interest particularly the student of teratology, for the malformations of the jaw are part of the larger subject of cranial defects. Dr. Herbst has collected examples of many rare conditions which are carefully described and fully illustrated. The chapter of most interest is that on cleft palate. It follows in the main the teaching of Karl Peter, whose explanation of the morphology of the elements involved in cleft palate differs from that usually followed in this country which is based largely on the work of Sir Arthur Keith. Peter believes that the cleft, where it is complete, instead of passing between the premaxilla and maxilla passes directly through the premaxilla itself. As is well known, in complete clefts the lateral incisor or a misshapen tooth which appears to correspond with it, lies most frequently on the distal side of the cleft and the separated premaxilla contains only the central incisor. It is true that the occurrence of supernumerary teeth in the region of the cleft is very common, and since they may not appear until many years after birth the exact identification of the morphology of the dental elements in the cleft region is difficult. Yet the appearance of the lateral (the pre-canine of Albrecht) on the distal side of the cleft is difficult to reconcile with the view that the cleft lies between the premaxilla and maxilla. Keith explains it by supposing that the lateral may be carried backwards by subsequent growth. He points out that exceptionally this tooth may be placed mesially to the cleft; it may lie at the apex of the cleft or more commonly it may be situated distally. These three positions are explicable by the later growth of the jaw. Peter, on the other hand, states that the cleft runs through the region of the lateral incisor, and in this way explains both its position on the distal side of the cleft and the frequent appearance of supernumerary incisors in cleft palate. The problem is primarily one for the embryologist. Perhaps the restatement of Peter's views in this book will stimulate some further investigation.

The second part of the book is by Dr. Apffelstaedt, and deals with malformations of the teeth. These, while of great interest to the dentist, are less intimately connected with the general problems of embryology and teratology than malformations of the jaws. Complete though this section is, we find a few omissions, notably the remarkable case recorded by J. H. Gibbs in the Transactions of the Thirteenth International Medical Congress under the title of Polyphyodontism in a Child, in which there were three rows of teeth superimposed on one another in the mandible. On the other hand, many of the malformations described are extremely rare, and the authors must have exercised a prodigious amount of industry to have compiled so full a catalogue of the monstrous and unusual. The anonymous translator has performed his task well and the book is free from that stilted phraseology common in translations.

Human Biology and Racial Welfare.

Edited by E. V. COWDRY. London: H. K. Lewis and Co., Ltd. 1930. Pp. 612. 28*s*.

AN omnibus volume of 25 essays by 27 authors which have this much in common, that they relate to the progress of natural knowledge on the one hand and to human welfare on the other. After an introductory chapter on life in space and time, the rest fall into four groups: the origin of man; man as a physiological unit; the effects of environment; the future. The essays are naturally of very unequal merit and interest. The chapter on the Reaction to Food is too much concerned with personal researches on vitamins. Similarly, the article on Adjustment to Infectious Disease misses a great opportunity, giving only rather a dull account of the antigen-antibody reaction. Sir Charles Sherrington and Dr. Fulton write on nervous integrations, Sir Humphry Rolleston on what medicine has done, Prof. W. B. Cannon on the integrative action of the circulating blood, Prof. Huntington (whose work is still less known than it should be) on the effect of climate—these and some of the others will be read with pleasure and profit. We only wish that there was a little more integration about the book as a whole.

Reflex Action: a Study in the History of Physiological Psychology.

By FRANKLIN FEARING, Ph.D., Northwestern University, Chicago. London: Baillière, Tindall and Cox. 1930. Pp. 350. 30*s*.

AT a time when "reflex action" occurs almost as readily to the psychologist as to the physiologist by way of at least verbal explanation of diverse and heterogeneous phenomena, a learned survey of the vicissitudes undergone by the conception since its earliest days is useful. The reader is taken lingeringly over centuries of thought and research, from the times of Descartes and Vesalius to those of the "Gestalt" school, and is amazed not only by the extent of the author's erudition but by his consummate skill in seizing what is essential and informative in a host of conflicting theories, thus enabling one to reach a position of orientation, a central place from which to look round. All this is admirably done, and human interest is added to the older material—necessarily somewhat dry—by reproduction of portraits of men well known in the history of the subject, and of title pages of old books.

We confess we find Prof. Fearing's comments at the close more valuable than much here set down to complete the historical picture. He distinguishes three variations of the concept as follows: (1) the "specific" concept regards reflex action as possessing certain physiological and psychological characteristics differentiating it from all other kinds of action; (2) the "genetic" concept, according to which there is no sharp break between reflex action at one end of

the scale and volitional response at the other; (3) the "mechanical" concept, which declares receptor-effector action to underlie and predetermine *all* behaviour. He puts his finger unerringly, it seems to us, on the cruxes of the situation; we must find out how volitional control is operative upon reflexes, must determine what we mean by automatism, must look past merely artificial terminology to what is actually happening when the organism adjusts itself. Prof. Fearing has not given us enough of his own decisions and conclusions; curiously, one of those he does offer—viz., "the sterility of the faith that mind and behaviour can be envisaged by number and measure has been exposed"—is precisely one which cannot be accepted without reserve.

General Practice (Some Further Experiences).

By ERNEST WARD, M.D.Cantab., F.R.C.S.Eng. London: John Bale Sons, and Danielsson, Ltd. 1930. Pp. 108. 3*s*. 6*d*.

Dr. Ward, whose volume "Medical Adventure" was favourably reviewed in these columns recently, presents in this little work some further experience of general practice with the same soundness and amusing shrewdness which characterised its predecessor. Fate, we learn from his words, has ordained for him a wide and varied experience of general practice. "I have," he writes, "had practices with clubs and without, practices on foot, push-bike, and car, medico-legal work, operations, and other side activities," and it is clear that the various episodes set down could only have come from the pen of one, who, in addition to possessing powers of observation and capacities for sympathy, had this wide range of experience. There is not a chapter in this book where the young practitioner will not find some guiding word—some apt piece of counsel for application in the conduct of practice.

Modern Infant Feeding.

By BERNARD MYERS, C.M.G., M.D., M.R.C.P. Modern Treatment Series. London: Jonathan Cape, Ltd. 1930. Pp. 160. 5*s*.

Dr. Bernard Myers has here supplied a summary of the physiology of the infant and the theory and practice of infant feeding, which, considering the small size of the volume, is remarkably complete. The method of artificial feeding, which is described in most detail, is a fairly simple dilution of cow's milk with added carbohydrate and low fat content; the uses of and indications for other preparations are also discussed. The last chapters contain accounts of the clinical features and the treatment of some alimentary disturbances, such as diarrhœa and marasmus. Like other volumes of the series to which it belongs, the book has the advantages of convenient size and low price.

Les maladies des vésicules séminales.

By E. CHAUVIN, Professor of Clinical Urology at the Medical School of Marseilles. Paris: N. Maloine. 1930. Pp. 216. Fr.40.

Prof. Chauvin has attempted to estimate the importance of the seminal vesicles as a source of trouble in urological conditions. As he points out in his preface, his countrymen are inclined to disregard the vesicles and concentrate their attention on the prostate, whilst American urologists consider the vesicles as of equal importance, at any rate in cases of chronic urethritis and cystitis. Luys alone, of all French urologists, has stressed the rôle of the vesicles in maintaining chronic infections and in acting as a primary focus in such troubles as gonorrhœal rheumatism. As a preliminary to his description of the pathology of the vesicles, the author devotes a chapter to their anatomy. Unfortunately, he illustrates his text by means of a plate which is somewhat misleading, since the vesicles are shown in an almost vertical position, whereas, in fact, they approach more nearly the horizontal and lie almost in contact with the upper margin of the prostate. No attempt is made to discuss their physiology, which is surely an omission in so comprehensive a work. The second part of the book deals entirely with pathology, and the third with surgery. Much extremely useful information has been here collected and presented in a readable form. It is curious that the author does not dwell on the utility of diathermy in cases of acute gonococcal infections; he leaves the impression that he is in favour of surgical intervention, and has little faith in less drastic methods. The work contains a very complete bibliography which should make it of use to all surgeons who have to deal with this region. The importance of vesicular infections is being more and more recognised, and the appearance of a complete treatise on the subject is to be welcomed.

Handbook of the Vaccine Treatment of Chronic Rheumatic Diseases.

By H. WARREN CROWE, D.M., B.Ch.Oxf., M.R.C.S., L.R.C.P., Director of the Charterhouse Rheumatism Clinic; late Consulting Physician (vaccine treatment) Yorkshire Home for Incurable and Chronic Diseases. London: Humphrey Milford, Oxford University Press. 1930. Pp. 52. 2*s*. 6*d*.

THE object of this small book is to set out in detail the author's method of treatment, by stock vaccine, of chronic rheumatic conditions. Dr. Crowe has used this form of treatment at his rheumatic clinic since 1928 with, he believes, considerable success; further, he holds it to be quite suitable for use in general practice. The vaccine is prepared from 155 different strains of streptococci, and one staphylococcus which he has named *S. deformans*. Very small doses are given, since in his opinion reactions are harmful and should at all costs be avoided. Although the author puts forward this treatment as one simple enough as to be eminently suitable for use by the busiest practitioner, this advice must be taken with caution, for pitfalls exist and error would be so disastrous to the patient: it is possible that the technique is more complicated than Dr. Crowe suggests. At one point in the book the author says: "Now, since all the rheumatic diseases respond in exactly the same way to vaccine treatment, whether they are thought to be microbic or not, surely the only possible inference is that they are all microbic." This is not sound reasoning, since it is impossible to tell how far the reaction is due to the injection of a foreign protein. Anyway, the theory and practice can be tested, for Dr. Crowe invites practitioners to visit his clinic and see the work in progress and the results obtained; he will, further, supply the vaccine free for trial.

THE LANCET.

LONDON: SATURDAY, AUGUST 9, 1930.

PLACENTAL HORMONES.

As long ago as 1905 HALBAN suggested that the placenta could act to some extent as an organ of internal secretion, and that it was capable of producing a supply of the hormone now called œstrin. The properties of this interesting substance have been mentioned in these columns on many occasions and it will be recalled that the physiological action which has so far received most study is the inducement of the cyclical changes of œstrus or "heat" in rodents and other laboratory animals. This result follows administration of the hormone either to the immature female before natural puberty, or to the mature animal in which the normal sexual cycle has been completely arrested following double oöphorectomy. Œstrin itself has no effect on the ovaries of the animals, and its action is principally upon the uterus and vagina, in which it brings about characteristic changes. A substance with very similar properties, and assumed by most workers to be identical with œstrin, is obtained from the ovaries themselves, principally from the liquor folliculi, and is also present in surprisingly large quantities in the urine during pregnancy. Consequently, the latter is a very convenient source for the preparation of the hormone and from this source it has now been obtained in a crystalline state by several workers.[1] This substance is of such remarkable purity that only about one ten-millionth of a gramme of the pure substance is sufficient to bring about œstral changes when injected into castrated mice. Its preparation from the placenta and from urine has been described by a number of workers, principally E. A. DOISY, A. BUTENANDT, G. F. MARRIAN, E. C. DODDS, and F. DICKENS. These investigations of its chemical properties show the substance to be weakly acidic, probably a lactone of a fairly complex hydroxy-acid having several hydroxyl groups. It is soluble in fat-solvents though it may also be obtained in aqueous solution, and it is rather surprisingly stable to strong acids and alkalis and to heat; boiling the solution has no effect and the purified substance may be redistilled at about 150° C. in a high vacuum.

It is uncertain whether the placenta actually secretes this hormone in the way suggested by HALBAN, or whether, according to another theory, the presence of œstrin is due to a protective action of the placenta in preventing the circulating maternal hormones from reaching the fœtus. It is clear, however, that this is not the only hormone having a special relationship to the placenta. In 1928 B. ZONDEK showed that implants of small pieces of human placenta into mice caused not only precocious sexual maturity, but also stimulated the immature ovaries so that ovulation sometimes occurred and corpora lutea were found in large numbers in the ovaries. A very similar result follows implants of pieces of anterior pituitary gland, as was shown in 1926 by P. E. SMITH and E. T. ENGLE and independently, in the same year, by B. ZONDEK and S. ASCHHEIM. Since injection of the untreated urine of pregnant women brings about closely similar results it follows that besides œstrin, this other luteinising hormone is excreted during pregnancy. In fact the luteinising property of the urine is the basis of ZONDEK and ASCHHEIM'S biological test for the diagnosis of pregnancy. There is thus a close resemblance between the properties of this other substance contained in the placenta, and those obtained respectively from the urine and the anterior pituitary, though it seems too early as yet to assume with ZONDEK that definitely the same substance is concerned. This second principle, which may be briefly referred to as the luteinising hormone, differs markedly from œstrin in its chemical as well as its biological effects. It is freely soluble in water, though not at all in fat-solvents, and is a very labile substance at once destroyed by boiling and damaged even by heating to 60–70° C. Probably other active substances are present in placenta and urine, though these are as yet less well defined. Thus claims for separate follicle-ripening principles (ZONDEK) and a substance bringing about mucification of the vagina (B. WIESNER) have been put forward. It is not yet generally agreed to what extent the difference in these principles is qualitative rather than quantitative. Perhaps the most convenient classification for the present is to distinguish (1) those hormones which act only via the ovary, such as the anterior lobe luteinising hormone; and (2) those primary sex hormones which are elaborated by the gonads themselves and are represented by the testicular hormone and œstrin. Whereas the second group are sex specific the first act equally well on the male or female sex organs and may be called the gonad-stimulating hormones, since they are without effect on the castrated animal.

From this point of view the recent work of COLLIP[2] [3] may be examined. In his first preliminary communication on the subject, which we noticed in THE LANCET of March 1st, 1930, no details were given of the method of preparation of the substance obtained from human placenta and used for clinical tests. He claimed only to have isolated from the placenta "certain micro-crystalline fractions" which showed great activity in promoting precocious sexual maturity. The criterion of activity was the occurrence of œstrus in immature female rats, accompanied in some cases by the presence of corpora lutea in the ovaries. Since the latter result was not constantly found and has now been abandoned by COLLIP as a criterion of activity of his extract, it is important to inquire what steps were taken to differentiate the material from œstrin, the presence of which in the placenta is well known. From the chemical point of view

[1] See THE LANCET, 1930, i., 94.

[2] Collip, J. B.: Canad. Med. Assoc. Jour., 1930, xxii., 215, 761.

[3] Collip, J. B., and Campbell, A. D.: Ibid., 1930, xxii., 219.

the evidence is not very definite. The method of preparation used by COLLIP is briefly as follows :—

The minced placenta is extracted with alcohol, the active principle being soluble in all strengths of this solvent. After removal of the alcohol by distillation and of the lipoids by extraction with ether, the solution is suitable for clinical use. Crystals can be obtained by addition of ammonia to the concentrated solution. The purified product is relatively insoluble in water and about 1 mg. is obtained from a kilo of placenta. The potency is unaffected by boiling for five minutes in dilute acetic acid, though the saline solution may deteriorate on keeping. No further chemical details are given of the properties of the hormone since the amount available as yet for experimental work has been insufficient. The unit of the purified substance is provisionally considered to be of the order of 0·0015 mg.

In this process the preliminary treatment with alcohol would facilitate the extraction of the œstrin from the placenta. After removal of the fats with ether, probably only a trace of œstrin would remain in the aqueous portion. The question arises as to whether this amount is responsible for any of the physiological actions observed by COLLIP—i.e., the production of precocious maturity in the experimental animals. COLLIP'S concluding words on this point are :—

"It has been suggested . . . . that œstrin or 'theelin,' as Doisy has now named the ovarian hormone, has not been entirely removed from our extract, and that the œstrus effects which have been obtained by its use may be attributable to traces of this hormone. Due to the consistent negative results which extracts of human placenta have given when tested on oöphorectomised animals, it was felt that this interfering factor had been adequately controlled. Larger doses will have to be given in the œstrin assay, over longer periods of time, to make this point clearer."

The wisdom of repeating and extending the experiments to cover these important points, and to indicate in a more definite way the true nature of the active substance or substances is obvious. The new name "emmenin" proposed for the active substance, in COLLIP'S most recent paper, seems appropriate, but its general adoption is likely to be delayed until final proof has been obtained of its identity. This important work has aroused so much interest in clinical as well as biochemical circles that the results of its further development will be eagerly looked for.

SEASONAL VARIATION OF INFECTIOUS DISEASES.

THE parasitic nature of epidemic disease having been established beyond all reasonable doubt, there has been a recrudescence of interest in the equally well established seasonal variation in endemic and epidemic infection, which occupied so much of the attention of the older school of epidemiologists. Dr. T. J. MADSEN, in an address[1] delivered at the London School of Hygiene, surveys the seasonal factor in Danish epidemics during the last 40 years. In Denmark notification of all infectious diseases has long been obligatory ; the land has long been sheltered from natural catastrophes and war ; there has been no great epidemic, and climatic differences in this small country are not marked. Seasonal variations are therefore of particular interest. Dr. MADSEN showed how the Danish morbidity statistics confirm in all details those noted by the older observers and conform closely with the seasonal periodicities of other European countries and North America. Scarlatina, diphtheria, angina tonsillaris, and acute rheumatism, for instance, increase during the autumn to a maximum in November, drop a little in December, rise to a second peak in January, and then fall to a minimum in July. Broncho-pneumonia, bronchitis, and influenza display a decided maximum in January and February, falling to a minimum in August. The incidence of croupous pneumonia follows the same curves, but does not reach its maximum until March–April. Another winter-spring group is formed by cerebro-spinal meningitis and encephalitis ; the former has its maximum in February and the latter in April–May. Among the summer-autumn infections are epidemic diarrhœa, typhoid fever, and poliomyelitis. The last of these runs a curiously opposite seasonal course to the other nervous epidemics, so that Dr. MADSEN wonders whether the intestinal canal may not play a part in its ætiology. Measles and whooping-cough show no regular seasonal fluctuations, but it is a peculiar feature of any measles epidemic that there is always a depression in the month of September. In the southern hemisphere the curves are reversed to correspond with reversed seasons.

Dr. MADSEN considers and rejects the theory that the variations may be on the bacterial side and allies himself with SYDENHAM in looking for some periodic change in man. N. FINSEN and L. ISACHSEN have found a periodic fluctuation in the quantity of hæmoglobin and the number of blood corpuscles, with a minimum in January and a maximum in July. J. LINDHARD has found a similar oscillation in the frequency and depth of respiration, the quotient of ventilation, and the alveolar carbonic acid tension ; this he ascribes not to temperature but to light. Dr. MADSEN therefore puts beside his other curves the sunshine returns for the year, and plots in one figure the general mortality-rate, the incidence of bronchitis and the respiratory frequency ; the curves follow one another with remarkable faithfulness. Annual fluctuations are also known to occur in bodily weight—a minimum in February and a maximum in September—and in the vitamin content of food. Dr. MADSEN treads cautiously among these fascinating possibilities, and points out the enormous field that yet remains unharvested. He ventures to suggest, however, as a prophylactic measure, an effort to secure more efficient light in the dark period, and urges the medical profession to encourage people to get out into the open air and sunlight as much as possible in winter.

The French Academy of Medicine lately listened to a discourse on a similar subject[2] by Dr. M. A. TRILLAT, who has been impressed by the importance of barometric pressure on the origin and duration of epidemics. In support of this thesis he quotes the mortality of the European influenza epidemic of 1889 to 1890, in which, he says, the

[1] Public Health, July, 1930, p. 309.

[2] Bull. de l'Acad. de Méd., 1930, ciii., 698.

mortality rose and fell with the humidity. He states that a similar correspondence has been noted in other epidemics, though not in the influenza epidemic of 1918. Here he supports Sir LEONARD ROGERS, whose numerous brilliant investigations have shown how closely the incidence of many infectious diseases in correlated with the "absolute humidity" of the atmosphere. Dr. TRILLAT himself attributes the action of humidity on disease incidence to its effect on the transmission of "droplet infection." Thus far most modern epidemiologists would be inclined to agree with him, but when he speculates that sudden barometric depressions cause an evolution of gases from soil and organic refuse, and that these gases form a suitable nutritive medium for organisms growing or multiplying in the air, he has probably lost the sympathy of the modern bacteriologist who no longer believes that specific pathogens can multiply to any extent in the atmosphere.

These two papers form an interesting contrast; the one attributes the action of season and climate to its effects on the host, producing alterations in resistance to infection. The other attributes the effects of season to alterations in the "transmission factor"; for example, a high humidity, as one sees in a common mist or fog, permits the maintenance and suspension of microbe-containing droplets for a longer period than in a dry atmosphere. Undoubtedly both factors are important determinants of seasonal morbidity, but which is the more important is unknown. Their weight probably varies greatly in different types of disease and environment. Finally it is interesting to note how all epidemiologists have given up "bacterial variation" as an important cause of the seasonal changes in morbidity, just put forward by PASTEUR. We wonder if they are always justified in doing so.

INTRABRONCHIAL DRAINAGE.

THE lung has been described as the most perfectly drained organ in the body. Free outlets, however, mean free inlets, and the bronchial system which gives such easy passage for the expectoration of secretions and debris facilitates the rapid spread of infection from the primary airways to the lung tubes, from one side of the chest to the other, and from terminal bronchi to air cells. In the chest, as elsewhere, we must learn to think of diseases as affecting not organs but systems. The pulmonary tract is one and indivisible. We might almost say that though there are five lobes there is only one lung. The ease with which fluids pass from the upper air passages to the main bronchi and their subdivisions is demonstrated by the injection of lipiodol. Under the fluoroscopic screen the oil can be seen to reach the terminal bronchioles within two or three minutes of its injection. A very slight tilting of the patient suffices to determine the flow to the right or left lung. Oil injected into a bronchial fistula of one lung can be made to flow into the opposite lung by a simple change of posture. It is not surprising that chronic pulmonary affections are usually bilateral, and we may well wonder how it can be that infection associated with bronchiectasis is, at times, limited to a single lobe, while except in the earliest stages of the disease unilateral tuberculosis is very infrequent. The manner in which the disease spreads to the contra-lateral organ makes it almost certain that this spread is due to inhalation from the affected side.

In a recent paper on intrabronchial drainage HAROLD BRUNN and WILLIAM B. FAULKENER [1] remark that proper evaluation has not been given to the mechanical factors which are present in nearly every case of pulmonary suppuration. They point out that drainage of a suppurating area in a lung may be external or internal. In the former, septic matter is removed by expectoration. In the latter, pus welling up from the diseased focus spills over into adjacent bronchi, or crosses the tracheal carina, to track into the opposite lung. Failure to appreciate the mobility of septic matter within the lung tubes may lead to error in diagnosis of the site of disease. Thus an upper lobe abscess may discharge its contents into the lower bronchi, and in such a case, after the patient has maintained the erect position for some hours, the physical signs may suggest a lower, rather than an upper, lobe lesion. On the other hand, if secretion is not excessive external drainage may suffice to maintain the dilated tubes of an upper lobe bronchiectasis in a fairly dry condition.[2] Mechanical factors, again, may determine the flow of pus from the left lower to the right upper lobe if the patient remains recumbent on his right side. The violent spasms of coughing to which the victims of pulmonary suppuration are liable is due to bronchial blockage. BRUNN and FAULKENER point out that the injection of lipiodol by the oral route causes no cough unless a bronchus becomes obstructed through the accumulation of oil, when violent coughing is at once aroused. Sudden occlusion of a bronchus will cause severe cough even though all possibility of bronchial irritation has been abolished by cocaine. This observation has an important bearing on the posture of a patient during certain operations on the chest. If, for example, during a pneumotomy for abscess the patient lies upon his sound side, pus from the diseased lung may spill into the opposite main bronchus, and the patient will be in danger of choking, unless the violent, and otherwise very undesirable, spasm of coughing set up leads to expectoration. Such a misadventure is obviated by bronchoscopy before operation, and the bronchoscopic cleansing of after operation is an additional safeguard.

Internal drainage is not limited to lipiodol injections or pulmonary suppurations. It is significant that in a "migrating" pneumonia the physical signs of consolidation over one upper lobe are often followed by the development of similar signs at the opposite lung base. Such an event is, perhaps, rightly interpreted as due to a spill over of infection and a flow determined by mechanical considerations.

ANNOTATIONS

QUARANTINE FOR AIRSHIPS.

FLIGHT across the world is rapidly becoming so common as to bring a new anxiety to public health officials. The possibility of the introduction of disease —especially yellow fever—by passengers from airships was considered seriously by the permanent committee of the International Office of Public Hygiene in May of this year. There are obvious difficulties to be overcome before satisfactory aerial regulation can be established; for example, little is yet known about the behaviour of mosquitoes towards aeroplanes and airships—whether they accompany them readily or not. Experience has shown that transportation of adult mosquitoes aboard sea-going ships is rare, but whether this distaste for foreign travel is extended to flying machines has yet to be investigated. Regulations would presumably be applied at aerodromes where incoming 'planes made their landing, but some special system of supervision would have to be devised for seaplanes.

It is not long since we referred [1] to the position of Australia, once happily isolated by a sea voyage, now at the mercy of every air pioneer. Plague and cholera which are prevalent in Bombay and Rangoon are not conveyed to Australia by sea, since the incubation period is shorter than the voyage, but the flight from Rangoon has been accomplished in 62 hours. Small-pox could actually be transported from England by flight during the incubation period. The disadvantages of quarantine in such cases are obvious; the time saved by the traveller, at considerable expense, would be wasted in idleness at the quarantine station. In India the fear of the introduction of yellow fever following the completion of the Panama Canal has now been replaced by the risk of an entry along the Imperial Airways route to Karachi. The report of the Yellow Fever Commission suggests a quarantine period of three days for persons sick with yellow fever, there being no known example of mosquitoes receiving infection from human feeding made after the third day of the sickness. The quarantine periods for airships coming from infected areas have not yet been decided.

MEDICINE IN INDUSTRY.

THE crisis in industrial production during the war and the revolution in commercial procedure which has taken place since 1918, with the resulting changes in our social system, have tended to bring the profession of medicine into far closer touch with industry and commerce. The importance of the human factor in industry is increasingly realised, and industrial medicine has begun to take its place as an integral factor in the communal life.

The essentials of a welfare scheme are lucidly sketched in a brochure [2] recently issued by the Industrial Welfare Society. It is shown that welfare work is neither a luxury for rich corporations nor a system of organised care likely to diminish the worker's sense of individual responsibility. Every industry has its own needs, and some of sufficient size find it desirable to hand over much of the welfare work to qualified medical men or women who, if they find such work congenial, can render to industry services of a high order which are, however, of so varied a nature that dogmatic pronouncements on their functions are likely to be of little or no value. Perusal of the Society's pamphlet may well raise a number of important questions in the medical reader's mind. It is noteworthy, for instance, that our greatest industry, agriculture, still remains outside any existing scheme such as operates in the urban areas. It has to be realised, again, that the unemployed members of the population tend to deteriorate in an alarming fashion during long periods of idleness, and that this deterioration should be largely a matter for medical advice and scientific study. A third and related problem is the increase noted annually in the amount of sickness benefit drawn by insured workers. Decrease in the infant mortality-rate has not so far shown any commensurate increase in the physical standard of the young entrants into industry or, to judge by the debate reported on p. 318, of recruits for the armed forces.

It is not only difficult but undesirable to lay down definite lines for medical work in industry, but it is obvious that, in a somewhat neurotic age, pension schemes, saving funds, holiday funds, and the stimulation of healthy hobbies and pastimes are of definite therapeutic value. Production has in the past ten years advanced at a rate out of all proportion to our consumption, and at the same time there has been an increasing tendency to reduce working hours. The result of these two factors is that leisure and the spending of money need guidance into channels leading to mental and physical health, lest they tend to defeat the very ends which we have expected. Education becomes more important, and the results of it, be they good, bad, or indifferent, must in the end be reflected in the national health. Thus we find it impossible to divorce matters merely industrial and medical from matters national and non-medical, for we are all members of one body.

THE FEAR OF DRUG ADDICTION.

IT is probably true to say that on the whole more suffering is caused to mankind by the terror of drug addiction than by the addiction itself. Many practitioners could cap the story which Dr. R. D. Gillespie makes the text of a recent article.[1] A patient for whom he had prescribed a hypnotic rang up next day to report that his wife had shrieked, wept bitterly, and pleaded with him not to take the medicine ordered lest he become a drug addict. Dr. Gillespie ascribes the confusion of the public mind to two origins: to the universal association of the words "dangerous" and "drugs," because they stand in this relationship in the title of an Act of Parliament, and to the divided teaching of the medical profession. The layman tends to speak of addiction whenever any drug which cannot be described either as a tonic or an aperient is being taken continuously. This habit of mind will often yield to explanation, but it is harder to convince him that it is safe to take a remedy which has been branded as pernicious by some eminent doctor. Nor are the chemists entirely without blame; Dr. Gillespie cites the case of a pharmacist who took upon himself when dispensing a prescription to read the patient a homily upon his self-destroying folly in taking the medicine ordered. Another offender is the medical witness at inquests. Too often he

[1] THE LANCET, 1928, ii., 613.

[2] The Introduction of a Works Welfare Scheme. I.W.S., 51, Palace-street, London, S.W.

[1] Brit. Jour. of Ineb., July, 1930, p. 6.

fails to draw attention to the wide margin between hypnotic and lethal doses of a drug. Not very long ago the veronal group was condemned as a whole because a man had succeeded in committing suicide by swallowing the uncomfortably enormous dose of 300 grains of adalin.

Dr. Gillespie quotes official figures to show that the suicide-rate from hypnotic drugs is by no means alarming, but he has been unable to find statistical evidence to show whether true addiction is associated with these drugs at all, or whether addiction leads to suicide. Clinically, addiction of any kind is uncommon in this country, and the records of cases are hard to come by. Another example of the confusion surrounding this subject is the fact that an example of "addiction and suicide" is quite often made out of a case in which, for instance, the patient, having taken 10 grains of veronal regularly for a year without increasing the dose, swallowed some lysol and died. Morphia and cocaine, the real drugs of addiction, provide a feeling of well-being and a refuge from anxiety; these benefits are not conferred by the veronal group, and in fact some patients complain of discomfort in the head after a dose. Dr. Gillespie remarks that he has yet to find the patient who craves an increase of dose for the dose's sake. The reduction of anxious preoccupation sometimes obtained from these drugs is only temporary and cannot be maintained by repeated doses. He finds a remedy for the unsatisfactory state of affairs in studying the patient. To order a hypnotic and at the same time to alarm the patient by warnings and official regulations is to nullify its effects, but the doctor who knows his patient knows to what extent he can be trusted to carry out a treatment. "In such a way," Dr. Gillespie concludes, "and without the fuss of drastic regulations which could only doubtfully save the few, and which would undoubtedly handicap the many, hypnotics may be used safely and successfully."

BENIGN MENINGITIS.

THE label meningitis carries so bad a prognosis that where patients with many or all of the classical symptoms have suffered from a benign type of malady with complete recovery the diagnosis is often considered doubtful. Nevertheless, there are cases of this kind in which examination of the cerebro-spinal fluid has left no doubt of some meningeal reaction. This was the lesion described, many years ago, by Quincke as "serous meningitis," and recently a good account [1] of some cases under the title of "acute aseptic meningitis" has been given by A. Gunther, of Gothenburg. These cases, 13 in number, were mostly in children, and nine of them came under observation in early autumn months. The symptoms were those of acute meningitis, and included a brief prodromal period followed by an abrupt onset, with headache, fever, vomiting, and drowsiness. Five of the patients showed apathy, but none lost consciousness. Stiffness of the neck muscles was noted in four cases. Lumbar puncture in each case showed cerebro-spinal fluid under pressure, mostly clear, with excess of protein. Cells, numbering up to over 600 per c.mm. in one instance, were present in excess, and mostly consisted of mononuclears. The sugar content of the fluid appeared to be within normal limits in the cases where it was estimated. The chloride content does not seem to have been calculated, and bacteriological examinations were all negative. All 13 patients made a good recovery, and on re-examination after periods varying from eight months to over seven years none of them showed any sign of permanent damage to the central nervous system in any way. Gunther discusses the differential diagnosis and possible ætiology of these cases under various headings. The acute infective types of meningitis, such as tuberculous or cerebro-spinal, can be excluded on the evidence obtained. Syphilitic meningitis is likewise excluded on general grounds as well as by negative Wassermann reactions in the fluid in his cases. Epidemic (lethargic) encephalitis is more difficult to exclude, but various points are against it, including the absence of any sequelæ. The diagnosis narrows down to the question of whether this acute aseptic meningitis is a distinct type of meningitis or whether it represents a meningitic or abortive form of infection by the poliomyelitis virus. Gunther is inclined to favour the second alternative. Approaching the subject from another angle, H. Sievers [2] discusses the differential diagnosis of tuberculous meningitis in children, particularly as regards cases of so-called "meningism" associated with otitis media or some acute infection in some other part of the body. He describes several cases which clinically and from the examination of cerebro-spinal fluid are identical with Gunther's, and he concludes that an exact diagnosis between meningism and tuberculous meningitis may be impossible except as indicated by the progress of the patient. Tuberculin tests do not help greatly in these acute cases; the fact that bacilli are not found in the cerebro-spinal fluid does not exclude tuberculous meningitis, and more elaborate tests last longer than the illness. Sievers favours the view that otitis media leads to some sort of irritation of the meninges with a lymphocytic reaction. Neither of the views here expressed will satisfactorily explain all examples of "meningism," however, and further work is necessary. It would be a good thing if the chloride content of the cerebro-spinal fluid was always estimated in such cases.

FURUNCULOSIS OF THE SALMONIDÆ.

FURUNCULOSIS has received renewed attention during the last few years on account of its rapid spread in salmon rivers in Scotland where the financial loss has been considerable, and in England and Wales where the damage, especially in trout streams, has been serious. An interim report [3] of the Furunculosis Committee of the Ministry of Agriculture summarises what is known of the various aspects of the disease and contains the results of recent investigations. The chief features of the pathology are the furuncles which are usually multiple, and the almost invariable septicæmia. The latter may cause death without discoverable local lesions or may occur in apparently healthy fish which can act as carriers and spread the infection. Histologically the furuncles are centres of necrosis and vascular congestion in the muscles or subcutaneous tissues which become softened but show no cellular reaction. There is no doubt that fish-farms have often been infected and that the disease has been spread by stock fish introduced from such sources in this country or on the continent. The possibility of a river becoming infected by salmon entering it from the sea is discussed in the report and dismissed as extremely unlikely on the grounds that no salmon has been conclusively proved to be infected unless it has been at least a short time in fresh water, that of

[3] H.M. Stationery Office. 1930. Pp. 65. 3s. 6d.

the many salmon caught and examined on their way down none has been infected, and that the irregular distribution of the disease in rivers whose mouths are adjacent is much against this view. There is, in addition, ample evidence of possible introduction from fresh water sources. The infective agent, *Bacillus salmonicida*, is easily recognised by its cultural characters, especially by the soluble brown pigment which colours the culture medium and by its pathogenicity for gold-fish, gobies, and frogs. When the virulence of a culture is low its identity can still be confirmed by complement fixation. Miss Williamson, who has been studying the disease under the Committee for the last two years, has attacked various aspects of the bacteriological problem and has published some results in appendices to the report. Among other important observations she finds that salmon eggs are not infected internally and can be disinfected and used for breeding even when they come from an infected source. The Committee recommends that importation of live fish should be prohibited, fish-farms supervised, and research on the outstanding problems continued and extended.

THE SENSORY PATHWAY.

Prof. J. S. B. Stopford has already published a series of studies on the arrangement and functions of the sensory system, and has impressed neurologists with the exactness and clinical applicability of his work. He has now dealt in more comprehensive fashion with the sensory pathway from periphery to cortex, being mainly, if not solely, concerned with one aspect—viz., that of objective change.[1] The equally significant questions of sensory overaction, of hyperæsthesia, of escape and release are not at present dealt with, since the researches along these lines are not yet complete. However, the fundamental facts are here set forth, and the functions of the various sections of the system are "welded into a harmonious whole."

Speaking generally, Prof. Stopford is convinced of the dual nature of the system, in the sense that both cutaneous and deep sensibility are divisible into sub-systems concerned respectively with protection and with discrimination. Probably no one conversant with the facts will dispute the general contention, even if details of interpretation cannot be universally accepted just as they are here stated. An ingenious effort is made to explain the phenomena of recovery after nerve suture in accordance with this duality. Although the anatomist and histopathologist is unable to distinguish any morphological differences in respect of regenerating fibres—and this fact may be thought by some to militate against dualistic interpretation—Prof. Stopford relies on the clinically demonstrable situation to argue that the protective system recovers function first and the discriminating system later. He assumes that in the circumstances "the paths by which cortical activity are aroused are out of action," and asserts, further, that "in the absence of activity of the sensory cortex, the corticothalamic fibres will not function." Both of these statements are open to criticism, though they are essential for his theory; a prick is felt, during processes of recovery, because "a prick can only appeal to the thalamus," and, as noted, the sensory activity of the cortex is declared to be in abeyance. Thus the further assumption is, that pain is appreciated as such only by the thalamus, and that the latter is conscious of its own activity. Objections which have been raised to this way of looking at the facts of clinical observation are rather summarily dismissed, and insufficient attention is given to the equally important fact that the hypothesis of thalamic release is not as yet erected on any sufficiently precise pathological basis however plausible it be. Indeed, we find constant reference to the action of "cortico-thalamic" fibres without any exact description of their anatomical locus, and without any hint that thalamocortical fibres may be intermingled therewith. The thoroughly unsatisfactory nature of the war-wound cases on which Head relied for his estimation of the site and extent of the sensory cortical system, and for revelation of its functions, is not made clear; in this respect precise clinical and pathological investigation is still required. Prof. Stopford has given considerable attention to sensory disorders resulting from medullary lesions, but does not appear to have seen cases in which the loss of sensibility consecutive to involvement of the descending root of the fifth has been of segmental type, not corresponding to peripheral branches of the fifth; and this appears to weaken his conclusion that the most cephalic part of the spinal nucleus of the trigeminal receives fibres from the inferior maxillary division, and so on in reversed order for the other two. In certain cases of syringobulbia the loss over the face runs across peripheral arrangements; Prof. Stopford does not take this circumstance into account. There is thus much in his thesis to provoke discussion, but no one will peruse its pages without being convinced of the strong case made out for physiological duality, and without recognising the numerous points in which a further sound addition to knowledge has been made by his researches.

[1] Sensation and the Sensory Pathway. By John S. B. Stopford, M.D., F.R.S., Professor of Anatomy, University of Manchester. London: Longmans, Green and Co. 1930. Pp. 148. 7*s*. 6*d*.

RADIUM TREATMENT OF RECTAL CANCER.

In recording his experience of the radium treatment of rectal carcinoma during five years ending last December, Sir Charles Gordon-Watson reports[1] on a group of 93 cases. He describes, as follows, the various ways in which cancer of the rectum can be rendered accessible to radium barrage: (1) Posterior barrage by open operation from the perineum with needles; (2) intra-abdominal radiation with needles or seeds; (3) radiation through the vagina; (4) intra-rectal radiation with needles or seeds; (5) radiation through the perineal skin; and (6) surface radiation on Columbia paste. So far, he says, he has not been able to employ distant "bomb" therapy. Recently a number of operable growths have been irradiated without preliminary colostomy. For intra-abdominal radiation Sir Charles considers a filtration of 0·8 mm. of platinum essential; as regards the danger of implanting needles into supraperitoneal growths, he points out that while emanation seeds are undoubtedly safer it has as yet been difficult to get a sufficiently heavy radiation. Favourable types for radium treatment have been squamous growths at the anal margin and small ones low down in the anterior rectal wall in women; the latter can be effectively treated by vaginal barrage. Sometimes an inoperable case has been rendered operable by preliminary use of radium, and the difficulties of radical operation have not been noticeably increased, though healing after operation has been slower than usual. Sir Charles points out, however, that radical operation should not be attempted after abdominal radiation owing to the likelihood of adhesions from the resulting plastic inflammation. Summing up the

[1] Brit. Jour. Surg., 1930, xvii., 643.

present position he says that for an operable cancer of the rectum radical excision should still be advised unless the patient is unfit or refuses the treatment, in which case radium should be tried as holding out "great though uncertain prospects of cure." For inoperable growths he believes that a small but increasing proportion of cases may be cured by radium treatment, while many advanced ones may be much relieved.

As an introduction to this paper, Dr. Cuthbert Dukes, director of the research laboratory at St. Mark's Hospital, records his observations on the spread of cancer of the rectum. He classifies the tumours in three groups, A, B, and C, according to the depth which cancer cells are shown to have reached. Three-quarters of the cases examined fell into Group C, in which the tissues surrounding the rectum are invaded by direct spread through the rectal wall, and in the first 100 cases examined there were 40 Group C cases in which metastases were found in the regional lymphatic glands. On the other hand, no evidence of lymphatic involvement was obtained in the 25 cases of Groups A and B which were examined. The conclusion reached by Dukes is that metastasis in the lymphatic glands is usually late and that it occurs only when the cancer has spread by continuity into the perirectal tissues. His observations emphasise the importance of upward lymphatic spread but minimise the likelihood of lateral and downward spread. As a method of estimating prognosis the routine method of cutting large sections to prove the anatomical depth of spread is likely to be valuable. Dukes has also made another interesting observation—namely, that protuberant growths are more likely to be Group A or early Group B cases without lymphatic metastasis, whereas excavated ulcers are more likely to be Group C cases, with at least a 50 per cent. probability of lymphatic spread. This observation suggests the advisability of removing ulcerated growths by an abdomino-perineal excision or by one of the several two-stage modifications which are now available; or if radium treatment is undertaken the path of upward lymphatic spread must be attacked as well as the growth itself.

WAS NAPOLEON AN EPILEPTIC?

NEARLY every writer on epilepsy enumerates the great men who have suffered from this disease, and Napoleon usually heads the list. F. M. Kircheisen [1] finds little to support this assumption. The evidence is, he says, contained in four sources—the memoirs of Lewis Goldsmith, Constant, Talleyrand, and Madame de Rémusat. Goldsmith, in a lampoon published in 1810 and widely circulated in several languages, states that a lady who was visiting Napoleon one night roused the palace with the news that he had fallen into an epileptic fit. Constant, a valet who published his memoirs in 1830, quotes the letter of a lady of the palace writing from Coblenz on Sept. 10th, 1804, in which she narrates that the Emperor had suffered on the previous night from "a severe shock to the nerves, or epileptic seizure." Nevertheless, in the same work, he states positively that Napoleon never had epileptic attacks and that the report of them was merely one of the many falsehoods concerning him which circulated among the multitude. Moreover, since on Sept. 9th and 10th Napoleon was at Aix and not in Coblenz, this particular story stands discredited. Talleyrand is a more formidable witness; he gives a circumstantial account of a seizure which occurred one evening in September, 1805, after he had dined with the Emperor. Kircheisen points out, however, that it is not likely that Talleyrand dined with Napoleon, because the Empress was at that time in Strassburg and the Emperor used then to dine only with her. Talleyrand, moreover, according to Kircheisen, was not noted for veracity; Napoleon hated him thoroughly, and the memoirs published in Talleyrand's name are a forgery by Bacourt. Madame de Rémusat burnt her first draft of memoirs and wrote the second from memory. She describes the scene related by Talleyrand as occurring in 1806, when Napoleon was leaving Mainz. Her account is rendered suspect by her statement that Napoleon was so overcome by the absence of his wife and Talleyrand that he shed copious tears and vomited. None of the four sources therefore are very convincing. Kircheisen justly points out that epileptic attacks recur and that, if Napoleon had really suffered from them, the fact would have been common knowledge to all his associates. Bourrienne, who was disgraced by Napoleon and certainly had no reason to be tender with him, states categorically that he never saw a sign of the disease in 11 years' close contact with the Emperor. It is almost conclusive that none of the medical men who attended him, and who left medical commentaries on his health, recorded that he had ever suffered from an epileptic attack. Sir Hudson Lowe, the Governor of St. Helena, would certainly have mentioned the fact had it existed. There is no doubt that Napoleon was highly neuropathic, but Kircheisen's essay leaves little ground for the belief that he was epileptic.

[1] Deut. Med. Woch., June 20th, p. 1057.

POST-VACCINAL ENCEPHALITIS.

THE treatment of post-vaccinal encephalitis with the serum or citrated blood of vaccinated persons has been followed by remarkable results. In the first case, recorded by Sir Thomas Horder,[1] a boy, 4½ years old, received intrathecally 5 c.cm. of the serum of his mother who had been vaccinated at the same time. He recovered rapidly and completely. J. Hekman,[2] of Rotterdam, has now reported nine typical cases treated in this way between August, 1929, and February, 1930, and quotes seven others. In all but two of these 16 there was quick recovery after the serum or citrated blood of a convalescent from vaccination was administered. The dose was usually 10 c.cm. and it was almost always given intravenously. The patients were children 3½ to 11 years old, and they received the blood of the mother or father, all but one of whom had been vaccinated at the same time. One child who recovered was apparently much benefited by the serum of the father, who had been vaccinated four years before. The effect of the treatment appears to have been very striking and certainly encourages the use of similar measures in cases of this serious complication, which is said to be fatal in about 30 per cent. of cases in Holland. Those who, like Hekman, favour the view that post-vaccinal encephalitis is due to the virus of vaccinia alone, are inclined to look on the dramatic issue of the treatment as proof that their view is correct. A notable feature was the rapidity with which the symptoms disappeared after injection of serum, although the patient had been vaccinated 10 or 13 days before the symptoms began and the serum was given two or three days later still when the vaccinia vesicles were completely developed. A second important fact

[1] THE LANCET, 1929, i., 1301.
[2] Bull. de l'Acad. de Méd., 1930, ciii., 539.

was that the donors of the serum were usually at the same stage of vaccinial infection as the recipients. Hekman thinks that the rapid action of the serum suggests an antitoxic rather than an anti-infective influence.

Grüneberg [3] reports two severe cases in children of 12 years and 1 year and 9 months who made good recoveries after receiving intravenously two doses each of the serum of recently vaccinated persons in quantities of 10 and 8 c.cm. respectively. The first dose was given about the fifteenth day after vaccination and on the third or fourth day after the onset of cerebral symptoms.

SCHOOLS FOR ABNORMAL CHILDREN.

A BOOKLET issued by the Board of Education and obtainable through any bookseller [4] shows the accommodation available for exceptional children, including the blind, the deaf, the mentally defective, the epileptic, those crippled in various ways, and those suffering from rheumatism, heart disease, pulmonary tuberculosis, and ophthalmia, as well as open-air schools for the delicate. The schools are not arranged according to the various disabilities, but a clear indication of the purpose of each is given in a separate column. Thus if a place is sought for a child with a particular disability, a glance down this column will show where it may be looked for; though it must, of course, be remembered that room can seldom be found for children not belonging to the authority that maintains the school.

The list indicates that accommodation in the country as a whole is more nearly adequate than it was, especially for children classified as physically defective, but for certain other types of defect there has been little improvement. Only one of the six schools for epileptics is entirely maintained by an education authority (Manchester), and the total accommodation for the whole country is only about a quarter of what is needed. The list does not make it clear what provision exists for cases of combined defect, but there is no doubt that it is quite insufficient. The deaf who are slightly mentally deficient or merely subnormal, as well as the deaf and partially blind, are well worth training; but though they cannot profit by the oral methods most valuable for the intelligent, very few special facilities are available. The position of the subnormal blind is somewhat similar; they cannot be taught to read Braille fluently, but they are not ineducable in other ways. The Ellen Terry Home for Blind Defective Children is noted in the list, but in the past this has been occupied by sightless imbeciles and not those for whom the need of special training is urgent. Subnormal and high grade defectives suffering from epilepsy are often accepted in the schools for epileptics, while those who can be deemed imbecile or ineducable are received in many institutions under the Mental Deficiency Act; it is for the intermediate class that little is at present possible. Combined physical and mental defect of the type of the cerebral paralytics also presents great difficulty, especially when the mental defect appears to be moderate. Schools for the unstable and delinquent children are not mentioned, doubtless because they are seldom definitely under the Board of Education, but there is a little accommodation for them in some of the schools described as being conducted by voluntary bodies mainly for the mentally defective, and there are the pioneer child guidance clinics. Use might well be made of the industrial schools, most of which have been so improved and humanised that the old prejudices against them vanish when they are visited. In many the care and influence are so good that the boy who is sent there may be far more fortunate than his comrade whose delinquencies are undetected or inadequately treated.

The second part of the list deals with institutions giving higher education of cripples and others with handicaps, and includes many famous foundations like Alton and Chailey, as well as the part-time classes for the deaf and blind. Part 3 enumerates the 31 nursery schools now established. The figures of accommodation show their inadequacy, and it is noteworthy that more than half of these schools are conducted by voluntary managers. But evidently a start has been made, and from other sources it is clear that local authorities are beginning to take an interest in the work.

THE "PRIMARY AVOIDABLE FACTOR" IN MATERNAL MORTALITY.

AN abstract of the first part of the interim report of the Departmental Committee on Maternal Mortality published this week, will be found on p. 321. The section of the report which in our view deserves most careful attention is the analysis of the cause of 200 maternal deaths by two expert obstetricians working on behalf of the Committee. The scheme set out in the report for an adequate national maternity service is on the general lines of that published by the British Medical Association,[1] while the plea for better education of medical students, as well as midwives, in obstetrics, only reiterates, however cogently, the arguments often set out in our columns and elsewhere. But the search for a "primary avoidable factor" in each fatal case is a new method of approach which has not been limited to the examination of records. Medical officers of health who have been entrusted with the duty of compiling these records, have been encouraged to enlist the help of a specialist in midwifery, with power to remunerate him for his services. The practitioners concerned have mostly welcomed and cordially coöperated in a calm survey of any case with a fatal issue, and its educational value to all concerned cannot be overestimated. The results of the investigation are extremely interesting. Excluding the 404 women who died from causes not due to pregnancy there remain 1596 deaths of which 626 show a primary avoidable factor; in other words 626 deaths might have been prevented. It is in some unexpected place that error is found, and this constitutes the chief value of the report. For example, it is estimated that many lives might have been saved merely by applying to cases of ante- and post-partum hæmorrhage the accepted medical methods of replacing lost fluid, while of 218 cases of eclampsia lamentably few were detected and treated at the stage of albuminuria when graver complications might have been avoided. Throughout the report there is evidence of a sympathetic rather than a hypercritical attitude towards the doctor and midwife, and it is because their difficulties are well appreciated that some of these difficulties, at any rate, are likely to be removed as the outcome of this inquiry.

THE Medical Research Council have appointed Maj. A. G. Church, M.P., Dr. F. E. Fremantle, M.P., and Sir John H. Parsons, F.R.C.S., F.R.S., to be members of their Industrial Health Research Board.

MODERN TECHNIQUE IN TREATMENT

A Series of Special Articles, contributed by invitation.

CCCV.

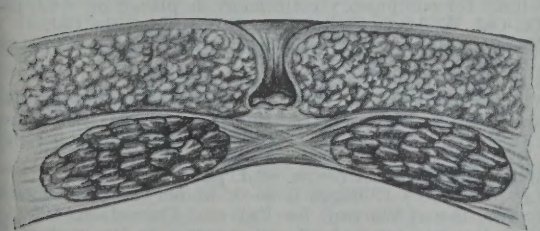
UMBILICAL HERNIA IN INFANTS AND ITS TREATMENT.

AN umbilical hernia in an infant is far more commonly met with at the present day than it was 20 to 30 years ago. Further, the mechanical treatment of such a hernia by a truss is apparently not nearly as efficacious as it was in years gone by.

The reasons for this definite increase in incidence are not far to seek. Many infants nowadays are not breast-fed, but are brought up from birth on patent foods. Such feeding predisposes to flatulence and abdominal distension, which prevent the abdominal wall musculature from acting to its greatest advantage, and which also to some extent prevent the normal development of the recti muscles. Hence at an early age the muscles of the abdomen are weak and flabby. Sooner or later the abdominal distension causes constipation, and this marks the commencement of a vicious circle. To overcome the constipation purgatives of a drastic nature are only too frequently given; the bowels very soon become exhausted, and a chronic distension ensues. Another factor contributing to the causation of an umbilical hernia is traction on the cord at the time of delivery or within a week after birth. The midwife is over-anxious for the "navel string" to separate. The mother frequently volunteers the statement that the nurse pulled off the "navel string" a few days after the child was born.

In these enlightened days the mother is usually instructed to discard the abdominal binder as soon as possible, being told that the child will grow more rapidly if it is not confined by tightly fitting garments. As an umbilical hernia does not often become manifest until some weeks after birth, it is, in my view, of the greatest importance that an infant should wear an abdominal binder until it is at least six months' old. If this advice were followed invariably there would be far fewer cases of infantile umbilical hernia attending our hospitals.

FIG. 1.



Section through the anterior abdominal wall showing the relation of the umbilicus to the recti muscles.

Mechanical Treatment.

Treatment should in the first place be prophylactic. If the causative factors enumerated above were instilled into the minds of midwives and mothers far fewer cases would require operative measures.

Undoubtedly a large percentage of umbilical herniæ in infants can be cured by mechanical means. It must be remembered that during the development of the embryo in utero an umbilical hernia is present from the fifth week to the third month, and that even under normal conditions it may be present at birth.

The normal umbilicus is a cicatricial depression in the mid-abdominal line situated about the junction of its upper three-fifths with its lower two-fifths. When observed from the front it is roughly circular and exhibits a certain amount of puckering. When viewed in cross-section the cicatrix is seen to lie immediately superficial to the crossed fibres of the rectus (Fig. 1). The upper part of the umbilicus is weaker than the lower. There is considerable separation of the recti in infants at birth, but after birth as the muscles grow they tend to approximate, and the linea alba becomes narrower. Generally speaking, the more cicatricial or fibrous tissue there is round the opening of the umbilicus, the slower its

FIG. 2. FIG. 3.

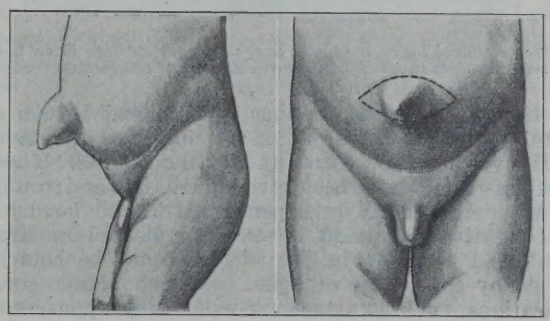


FIG. 2.—Umbilical hernia in an infant. This is the type which is difficult to cure by a truss.
FIG. 3.—Umbilical hernia showing incisions to enclose the umbilical cicatrix.

closure. Hence it is essential that no irritation be set up in its vicinity. It is important, therefore, that when treating an umbilical hernia the skin and subcutaneous tissues should not be folded in before any strapping or truss is applied.

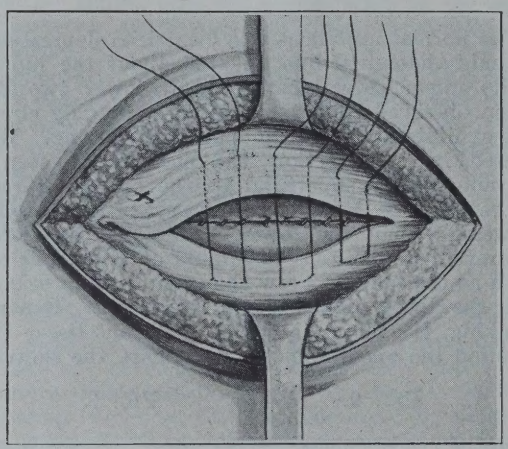
Probably the best method of mechanical treatment is to make a pad from a cork disc covered with muslin. It is essential that the disc be considerably larger than the hernial defect, otherwise it will defeat its own ends and cause the opening to become much larger. This warning may seem over-emphatic, but I have removed from infants under the age of one year ineffective trusses improvised from farthings, threepenny pieces, and sixpenny pieces. Possibly at infant welfare clinics the mother is told to make a truss from a penny or a halfpenny piece, and, left to her own resources, she considers a small silver coin would be better for her baby.

The truss should be retained in place by a piece of adhesive strapping. Should the application of the truss be difficult owing to the crying of the infant, a simple expedient which is always successful is to suspend the child by its feet and then to apply the truss.

Operation.

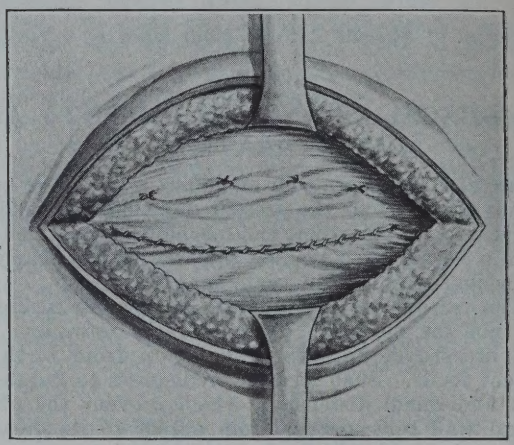
Mechanical measures should be tried for one year, and if at the end of this period the condition be stationary and the hernia a large one, operation should be advised. Some authorities state that mechanical means should be persevered with up to five years, but few mothers are patient enough to endure this, and, moreover, the skin of the abdominal wall becomes irritated after prolonged truss pressure, and the normal development of the recti muscles is interfered with. Another small but important point

FIG. 4.



The peritoneal layer is closed and mattress sutures have been inserted to produce horizontal overlapping of the rectus sheath.

FIG. 5.



The mattress sutures are tied, and the overlap is secured with interrupted sutures.

is that in a certain number of umbilical herniæ in adults there is a history of an umbilical hernia in infancy which was cured by wearing a truss. These patients would have been saved much time and trouble if an operation had been performed in childhood.

Operative treatment is always indicated in large umbilical herniæ (Fig. 2), which cannot be held in place by a bandage or truss. In such herniæ complications, such as attacks of colic, may appear and an operation should be advised before they occur.

The actual operation should be performed after the method advocated by Mayo. Transverse crescentic incisions are made above and below, whereby the hernia is encircled (Fig. 3). The sac is carefully defined and cleared of fat, and the neighbouring aponeurosis cleared for some little distance round the neck of the sac. The aponeurosis is then divided close to the neck by transverse incisions and the sac opened. The contents are now returned to the abdomen, but should any adherent omentum be present, it may be removed. Special care is directed to the margins of the opening, which must be carefully cleared. The sac, the adherent tags of omentum within it, and the overlying skin are then cut away completely, and great care must be taken to secure hæmostasis of the cut edges. The opening is now limited by two peritoneo-aponeurotic flaps, above and below respectively, and is closed by superimposing the upper flap over the lower and suturing them together by means of mattress sutures introduced through the margins of the lower flap and passed under and through the upper flap from within outwards (Fig. 4). The upper flap is then stitched over the lower, which it usually overlaps to the extent of an inch (Fig. 5). The wound is now closed with interrupted silkworm gut sutures without any drainage. The skin sutures are removed on the seventh day, and the little patient can, as a rule, be discharged on the tenth.

It is possible to preserve the umbilicus if necessary, but I do not admit the necessity. To state that for purely æsthetic reasons it is inexcusable to sacrifice the umbilicus seems to me to be overstating the case. By replacing a troublesome hernia which has been a source of annoyance for a long period by a neat horizontal scar the surgeon should give complete satisfaction to the infant's fond parents.

Years ago operating on infants for inguinal hernia was regarded with great aversion. To-day this is no longer the case; infants of all ages are constantly being operated upon for this form of rupture, and the time has surely arrived when more attention should be paid to the treatment of large umbilical herniæ occurring in infants.

CECIL P. G. WAKELEY, F.R.C.S. Eng., F.R.S. Edin.,
Surgeon to King's College Hospital and to the Belgrave Hospital for Children.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdr. G. D. Walsh is placed on retd. list with rank of Surg. Capt.

The following appointments are notified: Surg. Lt.-Comdr. G. S. Rutherford to *Pembroke*, for R.N. Hospital, Great Yarmouth. Surg. Lts. J. M. Sloane to *Adamant*; J. G. Ollerenshaw to *Emerald*; and F. L. A. Hughes to *Cyclamen*.

ROYAL NAVAL VOLUNTEER RESERVE.

The following appointments are notified: Surg.-Lts. D. C. Wilson to *Albury* and H. Winstanley to *Pembroke*, for R.N. Barracks. Proby. Surg. Sub-Lt. A. J. W. Beard to *Emperor of India*.

ROYAL ARMY MEDICAL CORPS.

Col. T. E Fielding, late R.A.M.C., having attained the age-limit for compulsory retirement, is placed on retd. pay.

Lt.-Col. W. D. C. Kelly, from R.A.M.C., to be Col.

Maj. (temp. Lt.-Col.) W. Mitchell to be Lt.-Col., vice Lt.-Col. W. D. C. Kelly.

Maj. E. B. Lathbury to be temp. Lt.-Col.

The undermentioned Lts. to be Capts.: E. H. Hall (prov.), G. A. Walmsley, A. Sachs, R. A. M. Humphrey, R. T. P. Tweedy, W. R. C. Spicer, G. T. L. Archer, and M. R. Burke.

Maj. A. S. Cane retires on retd. pay.

Lt. (on prob.) J. Beggs is secd. under the provisions of Art. 205, Royal Warrant for Pay and Promotion, 1926.

C. S. Gross is granted a temp. commn. in the rank of Lt.

ROYAL AIR FORCE.

Dental Branch.—Wing Commander C. L. Colbran (Lt.-Col. Army Dental Corps) is granted a permanent commission in this rank.

Capt. G. A. Ballantyne (Army Dental Corps) is granted a permanent commission as a Flight Lt.

The undermentioned are granted non-permanent commissions as Flight Lieutenants: Flight Lts. R. G. J. Charlesworth and H. I. Clapperton (temp. Capts., General List, Army, Dental Surgeons); Flying Officer P. M. Margand (temp. Lt., General List, Army, Dental Surgeon).

F. B. Sumerling is granted a non-permanent commission as a Flying Officer.

INDIAN MEDICAL SERVICE.

Capt. D. H. Mirchandani, late I.M.S. (T.C.), relinquishes the rank of Capt.

SPECIAL ARTICLES

MEDICINE AND THE LAW.

Successful Objection to Coroner's Finding.

THE High Court quashed another coroner's inquisition on July 24th. The inquest related to the death of a woman at Nottingham, and the finding to which objection was taken was that she died by falling downstairs "when under the influence of drink." The only evidence to justify the words quoted was that of her husband. Asked by the coroner: "Had she had any drink?" he replied, "Yes." The deceased had in fact had less than one glass of beer at a friend's house. The husband, if questioned further, would have said that she was a woman of temperate habits and was perfectly sober immediately before the accident. Her son and other witnesses were prepared to say the same. The Lord Chief Justice, who sat with Mr. Justice Avory and Mr. Justice Wright, said that the coroner's finding, involving a reflection on the dead woman, was arrived at on insufficient inquiry. On that ground the inquisition would be quashed and there would be a fresh inquest before another coroner.

This is the third occasion in the past six months on which THE LANCET has recorded the quashing of an inquisition. It need not be assumed, however, that the percentage of irregularities in proceedings before coroners is high. Though it may be tempting to compare the figures of quashed inquisitions with the statistics of convictions and sentences quashed by the Court of Criminal Appeal, the totals are not comparable. Persons convicted at quarter sessions or assizes have every opportunity of appealing; irregularities seemingly trivial and technical are often relied upon. On the other hand, coroners' inquisitions are not quashed for trifling irregularities, nor are inquests brought before the High Court for review unless there has been some patent and conspicuous cause of complaint. In the latest year for which statistics are available (1928) there were 31,553 inquests. During the same period some 7000 persons were indicted at quarter sessions and assizes. On review by the Court of Criminal Appeal, 22 convictions were quashed during 1928, convictions for another offence being substituted in two of these cases; 22 sentences in addition were quashed and other sentences substituted. More convictions are quashed than inquests, although the total of inquests held in the year is more than four times that of the total relevant criminal trials. Nevertheless coroners have need to be careful; there are impatient critics of their ancient office. In the Nottingham incident it is a pity that the witness did not find tongue to correct any possible misunderstanding. In the official statistics of inquests there is a separate class for deaths found to be due to drink. The finding which has been quashed might have misled the statistician, a result less unfortunate than the unjustifiable reflection upon the deceased which so much judicial effort has been needed to correct.

Professional Secrecy.

The court, as usual, over-ruled a protest made a few days ago by a medical witness who was being asked to disclose information about a patient. He was present on subpœna at the instance of a wife who was petitioning for divorce from her husband in undefended proceedings. The medical practitioner had attended the husband and was required to answer a question regarding his patient. The President of the Divorce Court directed that the evidence be given. The witness, before giving it, explained that he had his patient's written permission; otherwise he would have refused even at the risk of the personal consequences of disobedience to the court's direction.

The moral duty of professional secrecy is universally accepted. In the present state of affairs it is deemed cancelled either by judicial compulsion or by the patient's permission, and both these elements were present in the instance under discussion. Nevertheless the witness's resistance was not an idle exhibition of heroics. Such public protests are necessary if the present position is to be changed. Is there any adequate reason why the relationship of doctor and patient should be less privileged than that of solicitor and client? No solicitor is compelled to disclose in court his client's confidences. The legal profession enjoys complete privilege in professional matters. The benefit, of course, is that of the client not of the solicitor. Similarly, the patient should have the benefit of complete privilege as regards the non-disclosure by the doctor of details of health and treatment. Are members of the public less anxious for secrecy when they consult their medical than when they consult their legal adviser? Is the encouragement of frankness less desirable in the one case than in the other? The public sets a high value upon professional secrecy. It should insist on the fullest possible protection against disclosure. The medical profession will be willing enough to comply; it has its own tradition in the matter.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

DIETETIC THERAPEUTICS OF TUBERCULOSIS OF THE SKIN.

AT one of the recent meetings of the Wiener Gesellschaft der Aerzte Prof. Volk discussed the dietetic treatment of tuberculous lesions of the skin, which has received much attention of late. Prof. Volk emphasised the error of applying the expression "Gerson's" diet to this method, since Gerson's diet causes an alkalæmia, whereas an acidæmia is aimed at by Hermannsdorfer and Sauerbruch. The essentials of the diet recommended by the last-named observers are: (1) the exclusion of sodium chloride or its reduction to a minimum. (2) an attempt to effect a "transmineralisation" by giving the patient copious quantities of fresh, if possible uncooked, vegetables containing different salts and vitamins. The best results attained by this method have been in cases of lupus, which have made astonishing progress. In the special Lupus Institute of Vienna, which Prof. Volk controls, a special dietetic kitchen has been opened, out of which over 80 patients are supplied. The involution of the lesion takes place either without any reaction, the œdema disappearing and the nodules being replaced by an atrophic scar, or, in other cases, a reaction of the tissues takes place, with hæmorrhage, or even slight necrosis. These changes are followed by rapid healing, and may be manifest in different parts of the affected areas at

different times. In Prof. Volk's clinic the dietetic treatment is sometimes augmented by a combination of helio- and hydro-therapy, applied with due care, since the skin of such patients is extremely susceptible to external irritations. Temporary reactions, even psychical depressions or maniacal conditions, have been observed, but may be avoided if care is taken. Tuberculous patients seem to be specially liable to reactions such as a rise in temperature and increased secretion of sputum. Other dermatoses besides lupus have been treated with a salt-free diet and have responded favourably, notably some cases of pemphigus, psoriasis, and conjunctivitis eczematosa. One case of a very old-standing X ray ulcer was noted as especially favourable. Other authors have reported good effects in eczema, but it is unanimously agreed that tuberculous affections of the lungs are not affected by this diet; even in affections of the bones no remarkable results have hitherto been obtained.

MITOGENETIC RAYS.

Dr. G. Politzer, at the same meeting, read a paper on the present knowledge relating to the mitogenetic rays discovered by Alex. Jurwitsch in 1923.[1] He showed that from the roots of onions rays are emitted, which cause increased proliferation of cells and karyokinesis. Since then different observers have shown that numerous other plants and animal cells emit such rays. In man the normal blood, the voluntary muscles, and the bone-marrow emit rays which affect bacteria and certain kinds of yeast. The importance of these observations lies in the fact that malignant growths have a much stronger tendency to emit these rays than benign growths, and that in persons suffering from carcinoma or sarcoma the blood soon loses its property of emitting this kind of ray. The possibility exists that this phenomenon might lead to a means of early diagnosis of cancer if a practical detector for these mitogenetic rays could be found. Hitherto all the methods of detection suggested have been complicated and tedious to apply. Prof. Sternberg, Dr. Stempel, and Dr. Paltauf have recently investigated a new optic method, but this does not seem to give reliable results. At the moment, therefore, these rays are still only of theoretical interest to medical men.

RESECTION OF THE STOMACH IN OLD PEOPLE.

Patients over 60 years are, even nowadays, only rarely subjected to an extensive operation on the stomach, since the risk is deemed too great. The diagnosis of a malignant stenosis of the pylorus calls for operation even in quite old people, and even in less urgent conditions it may be justified. Prof. Finsterer recently showed two cases with the following histories. The first patient was 81 years old. Nine years ago he had an operation for an ulcer which had invaded the pancreas. The operation was performed under splanchnic anæsthesia, two-thirds of the stomach being resected. The patient still enjoys full health. The second man is now 80 years old, and has been suffering for 30 years from recurrent pains in the stomach and attacks of vomiting. The pain has increased since 1924, but operation was not considered owing to the age of the patient. In 1927, however, he had an attack of such severe pain that he demanded operation, however great the risk. Under splanchnic anæsthesia a callous ulcer was found on the lesser curvature near the pylorus. Half the stomach had to be removed with typical end-to-side anastomosis. In neither case was the ulcer malignant. Prof. Finsterer said that he has operated on 1400 patients of advanced age for similar conditions, and as a result of his experience believes that they should be given a chance.

[1] See THE LANCET, 1930, i., 1416.

THE LATE PROF. EMIL REDLICH.

After a rapidly progressing illness, Prof. Dr. E. Redlich, the well-known neurologist, died in his sixty-fourth year. From the outset of his medical career Redlich specialised in neurology, and he served as assistant in the neurological and psychiatric clinics of Vienna until, in 1907, he was elected chief of the neurological institute endowed by the Vienna branch of the Rothschild family. His scientific work was extensive, and there is no chapter in neurology to which he did not add a useful contribution. Redlich's splendid diagnostic powers and profound knowledge brought him deserved success in private practice. During the war he organised a special department for the patients suffering from injuries to the head, and his monograph on gun-shot wounds of the skull is a standard work. He has also taken great interest in encephalitis lethargica.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

SUPPLY OF RADIUM.

THE American Society for the Control of Cancer shows that only about 64 grammes of radium are available in this country. This is probably about the same amount as in France and twice what there is in Great Britain. Nearly 200 g. have been extracted from carnotite ore in the United States (Colorado and Utah) but most of this was absorbed in the manufacture of radium paint for war purposes and the ore which used to give 2½ to 3 per cent. of U_3O_8 is now exhausted. The yield of the remaining ore is about 1½ per cent. and the cost of production is prohibitive. The total amount of radium produced in the world is estimated at between 500 and 550 g. How much of this has been dissipated in the manufacture of luminous paint, especially during the war, is not known. The remainder could no doubt be used more efficiently if it were concentrated in recognised centres for the treatment of cancer, but this does not seem to be a practicable solution.

FEDERAL AGENTS PROVOCATEURS.

The antinarcotic administration of the Federal Government has recently come in for criticism, especially because of the employment of the *agent provocateur*. The Ohio State Medical Association points out that physicians have been prosecuted and fined for slight technical errors and that recently an honoured member of the Association, 71 years of age, was imprisoned in the Canton, Ohio, workhouse for nine months for dispensing tablets to an addict employed as a detective. The resolution points out further that the Federal Government has provided no institutional treatment for drug addicts but has issued a technical ruling that no ambulatory patient may be given a prescription for reduction treatment. The narcotic administration seems also to enrich itself on occasion by compounding with pharmacists who have unwittingly committed some technical violation of the highly complicated law.

RESEARCH IN SYPHILIS.

At a meeting of the Committee on Research in Syphilis held recently it was reported that grants totalling $91,515 had been allocated to twenty

ifferent investigators. Five clinics have been stablished in which attempts are being made to stablish criteria of cure and to study reinfection, elapse, and the development of complications. 'he Committee is chiefly engaged at present in studying he results of treatment in early and latent syphilis. Some 3000 case-histories are already available and they are being analysed by statisticians of the U.S. Public Health Service. The first results of the study will be announced in a paper on infectious relapse to be presented to the International Congress at Copenhagen in August.

Surrey.

Dr. J. Ferguson records a reduction in maternal nortality from childbirth to 3·1 from 4·9 in the previous year. In April, 1929, a medical officer with special experience was appointed to conduct 15 special antenatal clinics distributed through the county. Up to the end of the year 581 women attended for antenatal advice, and 89 for post-natal advice. The County Sanatorium at Milford was opened in October, 1928; by May 7th, 1929, the 298 beds were occupied and since then there has always been a waiting-list. Of the 795 patients admitted during the 15 months 280, or 35 per cent., had no tubercle bacilli in their sputum, but 67 of them showed tubercle bacilli after admission. Of the 435 discharged 143, or 33 per cent., never showed tubercle bacilli in their sputum. The average duration of stay before discharge was 134 days, and before death was 76 days. The number of bed patients was much larger than anticipated, and there is some difficulty in housing a staff capable of dealing with them. An improvement is expected when far advanced cases can be diverted to other county institutions. Artificial pneumothorax is performed in all suitable cases, patients returning for refills after discharge. There are approximately 1200 registered cowkeepers and 18,000 dairy cows in Surrey. During the last quarter of 1929 all the herds were examined. Mr. F. W. Medlock, the chief veterinary officer, points out that the value of routine examination is not only in the detection of cows with tuberculous udders, open cases of tubercle, and other pathological conditions, but it also facilitates education with respect to the hygiene of cattle and the prevention of disease. On inspection 7 cows were found to be giving tuberculous milk, 11 had tuberculous emaciation, and 20 had tuberculosis of the udder. The outside complaints of tuberculous milk numbered 18. In eight herds one or more animals were found to be giving tuberculous milk. One cow slaughtered showed tubercle of the udder. In six instances cows had been slaughtered or got rid of after the sample was taken, and the remaining members of the herd gave non-infected milk. In one case, where the complaint mentioned acid-fast bacilli resembling *B. tuberculosis*, the biological test was negative. The autopsy on 18 out of 19 animals whose milk was proved microscopically to be tuberculous showed advanced tuberculous lesions. The remaining animal was slaughtered by the owner before the result of the examination was known. Mr. Medlock notes that there is considerable misunderstanding by the public of the nomenclature adopted for graded milks. An expenditure of £20,000 has been undertaken as an unemployment relief scheme for the clearing and improvement of the river Wandle.

Dumfries.

Dr. John Ritchie ascribes the increased death-rate chiefly to influenza in the early part of the year. There were 54 deaths from influenza and 63 from pneumonia, against 11 and 35 in the preceding year. In 1929 the prevalence of scarlet fever was mainly in isolated country districts. The notifications of puerperal fever showed an increase, probably because the provision of hospital accommodation secures more effective notifying. A case, which was admitted to hospital as erysipelas, was finally diagnosed as "sokodu" or rat-bite fever, and made a good recovery. Another local case of the same disease was treated in hospital in 1914. The county veterinary inspectors, Mr. F. A. Davidson and Mr. G. A. Sangster, report an increase in the dairy farms owing to the opening of a new creamery at Carlisle. The new firm collects the milk at the farms, and the premises of cowkeepers who were registered for the first time as dairy-farmers have needed reconstruction. Contagious abortion is still on the increase, and as there is no evidence of undulant fever it is suggested that there are probably several strains of the organism which causes the disease in cattle. Regular inspection is leading to the earlier discovery of tuberculosis in cows, and the "not advanced" cases now exceed the "advanced" among the animals slaughtered. Bacteriological examinations have increased in number owing to the difficulty of distinguishing certain types of contagious mastitis from tuberculous mastitis. The use of a mild antiseptic for washing the hands of milkers and the cows' udders has tended to decrease the number with sore teats. The veterinary inspectors give reasons for suggesting that the designation "Certified" and "Grade A" should be dropped, and that "Grade A (T.T.)" and "pasteurised" should be the only designations.

Plymouth.

Dr. A. T. Nankivell, as in past years, includes reports by medical members of his staff on various sections of the work. Referring to the continued high maternal mortality, he suggests as remedies: (1) better education of doctors and midwives;

(2) greater use of antenatal clinics; and (3) the provision of a city maternity hospital. Dr. Marion Smellie says that during 1929 1100 pregnant women attended the clinics, including 414 primiparæ, but only 161 came back for postnatal examination. A post-graduate course held in October was attended by 68 midwives. Immunisation against diphtheria is becoming more popular. Preliminary Schick testing is only used in children of 9 years and over. During the year 259 susceptible children were made Schick negative. It has been found more satisfactory to give the three injections at monthly intervals, and a Schick test five weeks after the third injection. Dr. E. J. Hynes complains of the number of cases of diphtheria still admitted to hospital in a hopelessly advanced stage of the disease. Apparently practitioners of the district do not even now realise that a negative swab does not exclude diphtheria, and that in suspicious cases antitoxin should not be withheld pending the pathological report. Scarlet fever serum has been found useful when given during the acute stage of the illness, as well as for the temporary immunisation of contacts. Its supply free of charge to hospitals and institutions is advocated. Dr. Mildred Thynne says that investigation showed 8 per cent. of children from 1 to 5 years on the register of the centres to have threadworms. The affected children sometimes come from good homes. It is hoped to overcome the apathy of parents with regard to this complaint. Dr. Nankivell is disappointed at the slow progress with regard to three insanitary areas scheduled four years ago. There is still a shortage of houses. Dr. Nankivell has strong views on the propagation by feeble-minded and mentally defective. He quotes the recent remarks of a high court judge in support of sterilisation, and insists that the problem created by the steady and uncontrolled growth of these degenerates, who increase at the rate of about 2500 every year, must be faced by hard thinking.

Paisley.

Dr. G. V. T. McMichael's report shows that housing is the dominating problem at Paisley and intensifies the need for hospital provision for cases of tuberculosis, pneumonia, infectious diseases, and maternity cases. 15·1 per cent. of the dwellings are one-roomed, and 47·8 two-roomed; 572 houses are unfit for human habitation and past repairing. About 30 per cent. of these small houses are overcrowded, and there may be as many as nine persons in a one-roomed house. The council have decided to proceed with the erection of 125 two-roomed and 375 three-roomed houses at rentals approximating those of the uninhabitable houses—£12 to £15 per annum respectively. The death-rate was the highest since 1924. Nearly one-fifth of all the deaths were ascribed to influenza and pneumonia, though 534 of the 738 notified cases of pneumonia were treated in hospital. The numbers admitted to Barshaw maternity hospital—326 for confinement and 166 to the antenatal wards—taxed the accommodation, and extra sessions and an increase of staff are required to enable a postnatal clinic to be established. The maternal mortality was the lowest on record, with no deaths from puerperal sepsis. The dental clinic was attended by 64 mothers and 369 pre-school children. According to Mr. A. M. Marshall, the senior dental surgeon, the condition of the teeth of the school entrants is still deplorable and his work would be much more effective if more time and money were spared for the pre-school child. He estimates that 5000 children enter the Renfrewshire schools annually with 20,000 teeth requiring treatment. Only 48 persons died of pulmonary tuberculosis, giving a rate lower than ever before, but 40 deaths occurred from non-pulmonary tuberculosis. Little progress was made with the proposed joint county sanatorium.

West Gloucestershire United Districts.

The rural districts of East Dean, Gloucester, and Lydney, and the urban districts of Awre, Newnham-on-Severn, Westbury-on-Severn, and Coleford (added in 1926) comprise the area under the control of Surgeon-Captain O. W. Andrews. It is hoped that by the end of 1930 water will be laid on to the houses in most parts of Coleford and West Dean. Newnham Urban District Council has taken over the proprietary water-supply, which is to be augmented by the driving of an adit into the hillside. A table shows that the death-rate from tuberculosis has been reduced from about 1·0 to about 0·5 since 1913, but that from cancer has risen during the same period from about 0·8 to 1·5. Surgeon-Captain Andrews is an advocate of sterilisation for the mentally deficient. Housing has made progress in the districts most in need, whilst in certain parts of the area the population has declined. The advantage of the keeping of goats by poorer families living near a common is emphasised, with especial reference to those districts where all the milk is bought up by factories.

The Isle of Sheppey Joint Districts.

This area includes: Sheerness (p. 16,890), Queenborough (p. 3189), and Sheppey (p. 5656). Dr. W. C. D Hills states that there are no hospitals in the island, with the exception of the poor-law institution at Minster, which it is hoped will soon be converted into a general hospital with maternity wards. The bridge connecting the island with the mainland has been made free from tolls. Eight cases of small-pox occurred in Sheerness and three in Sheppey. The three districts are, to some extent, combining their sewerage arrangements. The housing question is an important one in Sheerness, which also needs a public supply of hot baths. Anti-mosquito work is in constant operation in all three districts included in this area. The maternity and child welfare work in Queenborough has been transferred to the county and a local nursing association has been established with a district nurse-midwife resident in the borough. Antenatal consultations have made a beginning. The increasing urbanisation of part of the rural district makes greater attention to the water-supply necessary.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED JULY 26TH, 1930.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox 109 (last week 126); scarlet fever, 1750; diphtheria 1278; enteric fever, 113; pneumonia, 467; puerperal fever, 33; puerperal pyrexia, 99; cerebro-spinal fever, 16; acute poliomyelitis, 17; acute polio-encephalitis, 2; encephalitis lethargica, 14; continued fever, 1; dysentery, 14; ophthalmia neonatorum, 11. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on July 29th–30th was as follows: Small-pox, 221 under treatment, 4 under observation; scarlet fever, 1809; diphtheria, 2000; enteric fever, 35; measles, 259; whooping-cough, 84; puerperal fever, 28 (plus 15 babies); encephalitis lethargica, 120; "other diseases," 24. At St. Margaret's Hospital there were 16 babies (plus 9 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there were no deaths from small-pox, 3 (1) from enteric fever, 22 (7) from measles, 7 (1) from scarlet fever, 12 (2) from whooping-cough, 39 (9) from diphtheria, 42 (10) from diarrhœa and enteritis under two years, and 17 (3) from influenza. The figures in parentheses are those for London itself.

Four of the deaths from diphtheria were in Liverpool, 3 in Manchester, and 2 each at Bristol, Chester, Halifax, Leeds, and Sunderland. Four deaths from diarrhœa were reported from Birmingham, 3 from Coventry, and 2 each from Nottingham, Manchester, Salford, and South Shields.

The number of stillbirths notified during the week was 267 (corresponding to a rate of 40 per 1000 births), including 50 in London.

CORRESPONDENCE

THE TREATMENT OF PULMONARY TUBERCULOSIS IN SWITZERLAND.

To the Editor of THE LANCET.

SIR,—Dr. Harrison's article deserves a wide popularity for it illustrates a very human failing—that of following the herd. Because treatment in Switzerland is thought to be the best obtainable no trouble is taken to ascertain if this is actually the case, or whether equally good treatment can be obtained in England. Owing to the popularity of treatment in Switzerland people are eager to tell of their cures and reluctant to tell of their failures. The chief criticism I have to offer is that Dr. Harrison's views are expressed too mildly. As the tourist industry in Switzerland is the chief it is exploited to the utmost in the case of patients in a sanatorium. They are regarded as guests in a hotel rather than patients in a hospital, and little attempt is made to treat them with a view to giving the best chance of recovery. To my own knowledge patients are encouraged to go to dances against their inclination, and also to a weekly cinema which would not be a financial success if a sufficient number were not present.

My own personal observations lead me to believe that it is a great mistake that phthisical patients should be banished to a foreign country where home comforts and familiar ways are absent and where a necessarily prolonged treatment is begun under such discouraging conditions.—I am, Sir, yours faithfully,

London, July 28th, 1930. M. G. DAVIS.

To the Editor of THE LANCET.

SIR,—The fresh-air idea is not likely to be given up in the treatment of pulmonary tuberculosis. Fresh air can be found anywhere, but at high altitudes it is rarefied and is rich in actinic rays, independent of direct sunshine. In consequence of the low barometric pressure the blood condition of patients improves. The increase of the red blood-cells is not a temporary one, but remains on descending to the lowlands once again. (In this connexion experiments with anæmic patients are hardly to be mentioned.) Furthermore, the blood tests—sedimentation and differential cell count—show greater and quicker improvement under treatment than at lower altitudes. Physicians who have to deal with tuberculous patients know the importance of this fact and the improved bodily metabolism cannot be overlooked.

Besides the richness of sunshine, the high altitudes offer an unrivalled richness of ultra-violet rays. Even without sun and on snowy days our patients become sun-burnt, and the effect of this ultra-violet radiation on metabolism and the blood condition is very important. The dryness of the air makes it possible for our patients to spend most of the hours in full winter out of doors, even without sunshine, which by the way is present for weeks in full glory at the time when there is only mist and fog in England. It is not true "that 19 out of 24 hours" of each day must be strictly spent within doors. On the contrary, 8–10 hours can be easily spent out of doors in the cold and dry air, and even our bed-patients can be rolled out in their beds on to their balconies during the greater part of the day. During intense cold weather (a rarity) it is, of course, necessary to regulate the closing of doors and windows more than in the lowlands; but one is not obliged to close them entirely. The amount of fresh and good air available at night is more beneficial than a whole roomful of damp, moist, and smoky air in the lowlands. Certainly there are days with bad weather when the open-air cure is restricted, but these are exceptions, and there is hardly a day in winter or summer when a patient cannot be out of doors. And what is happening to the patient in damp England at that time in the winter? Remembering the climate at home English patients are often astonished to hear that out here they can "cure" out of doors in bed and on their chairs in bad weather.

It is only for a very short time during the shortest days of the year that "the sun is only visible over the mountain tops for about five hours a day." How long does the sun at this time appear in England and with what strength? Dry snow and cold are far better than rain and mist in the lowlands just at that time. The same is true of the so-called "snow melting time." The weather then is either beautiful, warm, and sunny, or snow falls, and this is preferable to the treacherous, windy, and damp weather with April showers then prevailing at the low altitudes. The patients in our Swiss sanatoriums can find as much occupation as in the English ones and can watch the winter sports quite well without risk of being debilitated (as Dr. Harrison suggests) by the intense cold on the ice-rinks, &c. They can drive about in the sunny country, play games, hear good music, and have cinema shows even in the sanatorium and—what is certainly very helpful and must not be overlooked—they can mix with people of other nationalities, learn other languages, and understand customs and doings other than those of their home islands. In long years I have never heard any complaint about the "monotony" of the winter landscape, which changes every day. What about the monotony of a sunless misty winter period in England? And the "same dreary tramp along a very ordinary road with the perpetual snow all round" has a lot of variety. All the woods are open for walks, squirrels are playing, birds are flying about, both so tame as to come to one's hand; and one can see people ski-ing and tobogganing. I am told that in some English sanatoriums there is a "variation" of walks, one for Monday, one for Tuesday, one for Wednesday, and so on. Well, is this less monotonous than to know the menu of the meals for each day of the week and with the perpetual damp and cloudy atmosphere around?

Hundreds of physicians knowing the high altitudes and many thousands of patients, are convinced that, though not a panacea, the high altitudes will always have great advantages in the fight against tuberculosis. Apart from the physiological elements there are results to be considered. A great failure—I speak from bitter experience—comes from the fact that often patients who are sent out to our altitudes are ordered back at a certain time regardless of their present condition. Thus English patients who have been doing well during the winter are obliged to break off their treatment too early and grow worse at home. If they were allowed to remain out during the spring and summer they would continue to improve. I cannot over-emphasise the importance of continuous treatment at high altitudes; it is far preferable to "wintering" only.

Large statistics of permanent results—seven, ten, or more years after the termination of the treatment at high altitudes—have been drawn up by Turban, at Davos, by Ruge and Bernstain-Kohan, and by myself, at Arosa, and by others. They speak for themselves. Of course, a larger experience by Dr. Harrison than mine will be welcome; I personally base mine only on 31,000 patients treated at Arosa—patients from countries all over the world. However this small material, together with observations made during travel over nearly the whole world and examination of patients everywhere, has convinced me more and more of the superiority of the treatment of pulmonary tuberculosis at high altitudes. Thousands of records of English patients of mine who had failed to improve in England and have found their healing up here, confirm this my conviction.

I am, Sir, yours faithfully,

O. AMREIN,
Medical Superintendent of the Altein-Sanatorium and the Sanatorium Furka, Arosa.

Arosa, Switzerland, July 26th, 1930.

AMERICAN STUDENTS AT BRITISH UNIVERSITIES.

To the Editor of THE LANCET.

SIR,—I read with a great deal of interest your editorial concerning medical students from the United States in English universities in the June 7th issue of THE LANCET. You will, perhaps, be interested to learn how this situation is viewed by some people in the United States. There are three groups of students who leave the United States to go to English universities to pursue medical studies. The first, group 1, and perhaps the only group actuated by praiseworthy motives, are the post-graduate students. These are men and women who have secured their medical education in the United States, have earned the degree of Doctor of Medicine, and have been licensed to practise. They usually cross the ocean to acquire more knowledge and greater proficiency in a particular preclinical science or specialty. Very often such post-graduate students are sent to London on a scholarship by the hospital in which they have completed their internship. In all instances they are men and women who reflect creditably upon themselves and the institutions in which they carry out their studies.

The remaining two groups (groups 2 and 3) are the undergraduate students. The first of these (group 2) comprises those who have completed their pre-medical requirements and have not as yet begun the study of medicine. The greater majority of these apply for admission to American medical schools. More than can possibly be accepted are eager to gain admittance, and of these those practising the highest grades and greatest promise for success in medicine are accepted. The remaining number must seek education elsewhere. The most natural place is England. They have found from previous experience that when chances of being accepted in an American medical school are gone it is quite easy to gain admission to an English school. Those who are of Italian descent just as readily gain admission to the Italian medical schools. This in no way reflects with any credit on either the English universities or Italian schools. Those of us who have secured our undergraduate medical training in American medical schools regard those Americans who have been educated in English schools as inferior. This is natural, because the English universities have recognised what the American schools have rejected.

There are, of course, those who have always evinced a desire to study only at an English medical school and have applied to no American medical school for admission. Such persons should be admitted, if they possess the right qualifications, to English universities, and if the English schools would limit their choice to such applicants they would gain much in prestige among Americans. It is quite easy to learn just who such persons are. Everyone applying to an American medical school is recorded by the American Medical Association. If he applies to a dozen medical schools this fact is noted as many times. The procedure for the English university authorities to follow would be to write to the American Medical Association regarding any application they received from the United States. If he had applied to American medical schools and had been rejected this fact would be known. They then could refuse admission to such a student. If he had only applied for admission to the British medical school this would also be known to the American Medical Association. The latter type of student is, on the whole, much more desirable. He has not been found unsuitable by the American schools.

The third group of students are those who have had some undergraduate medical training in the United States and who find it impossible to continue their training here. It is then natural for them to apply to English medical schools for the completion of their medical course. This group comprises those who have been expelled either because of poor scholarship or because of serious flaws in their moral make-up. Any medical student expelled from an American medical school has his name sent to the American Medical Association from where it is sent to the deans of the accredited medical schools in the United States. Such a student can never enter another American medical school. There is but one thing for him to do if he desires to continue his medical training, that is to apply to an English medical school

There is a solution to this problem. It should be made a matter of routine of the admitting board of every English medical school to write to the American Medical Association concerning each application they receive from the United States. They would then be in possession of the facts and would be able to decide intelligently just who is worthy of admission to the English medical schools.

Very cordially yours,

July 8th, 1930. EDWARD PODOLSKY.

*** With regard to Dr. Podolsky's group 2 the facts are not in accordance with our experience. It is the considered judgment of those most competent to form an opinion, voiced by Dr. Colwell, secretary of the Council on Medical Education, in a letter to the American Consul in Edinburgh, that "all those who are quantitatively and qualitatively qualified do secure admission to approved medical colleges." That agrees with the statement in THE LANCET published after an investigation made some 18 months ago with the assistance of the deans into the medical curriculum of 12 great American universities. (Special Supplement of THE LANCET on "Medical Education in the United States," Jan. 5th, 1929.) That the rejected naturally obtain education in England does not tally with the experience on this side. For example, of 800 American applicants at the University of Edinburgh in 1930, 11 were accepted, their testimonials being generally in the form of a letter direct from dean to dean. In group 3 there may be many students who apply in this country for admission, but, so far from it

being quite easy, it is quite difficult to learn their records in the absence of Statutory bodies in the United States with whom to communicate. The size and influence of the American Medical Association is not in question, but it has not the necessary constitution to enable it to act in the way suggested. There are, however, in the United States four bodies which might be recognised as having a Federal position, and unhampered by the Doctrine of States Rights. It is to be hoped that in one or other of these directions our General Medical Council may find a way to the institution of that reciprocity for which the members of the Council and leaders of educational thought in America have been working intensively for some time.—ED. L.

THE INTERPRETATION OF DENTAL RADIOGRAMS.

To the Editor of THE LANCET.

SIR,—It is unfortunate that Mr. Pitts, judging from his letter in your issue of July 26th, has not made himself familiar with the literature of his subject or with present-day circumstances. He states "If Dr. Brailsford would refer to Weston Price's book on dental infections, he will find there an instructive chapter on the capabilities and limitations of X rays." May I state that if Mr. Pitts would refer to an article on this subject in the *British Medical Journal* of June 16th, 1928, or the reprints of this article which appeared in the *Dental Surgeon* on July 14th, 1928, in the *Medical Annual* for 1929, and the *Mouth Mirror*, he will see from my criticism that I had read Weston Price's book, but that my experience was not in entire agreement with his conclusions. In this article I stated:—

"Weston A. Price, who with a team of dental surgeons, bacteriologists, and laboratory workers has carried out a very extensive investigation on dental sepsis, considers that 10 per cent. of the teeth with septic roots give no indication of this on the radiograph; but even so, most of the process illustrations which he used in describing the 'failure' of the radiographs showed definite though 'slight' changes, yet process illustrations cannot give the detail of the original radiographs. There is no doubt in my mind that the figure of 10 per cent. can be considerably reduced by skill in the radiographic technique and the care exercised in examining and interpretating the radiograph."

In a further article I stated "Teeth which do not show changes on a good radiograph and which are not painful are not the source of chronic toxic absorption. In other words, every tooth which is a source of chronic toxic absorption shows changes indicating this on the good radiograph."

Every radiologist is acquainted with the fact that dental surgeons do not all hold the same opinion with regard to dental sepsis. Some will act on the radiographic findings and extract teeth only shown to be septic, others will extract teeth with "clinical" signs and ignore obvious lesions shown on the radiograph, others will ignore clinical and radiographic evidence of sepsis and preserve teeth for "appearances" or for the attachment of a denture, yet others will extract teeth which show no definite clinical or radiographic evidence of sepsis. A note of caution regarding the treatment of obscure dental sepsis which I have given in a previous article reads as follows:—

"The reason for the doctor's recommendation for the wholesale extraction of a patient's teeth is based on his experience that such treatment results in the alleviation of certain symptoms. Equal success attends the extraction of only those teeth shown by the radiograph to be septic and probably leaves the patient with most of his or her own teeth and consequently not so liable to the digestive disturbances experienced by many edentulous patients."

Commenting on radiologists' reports Mr. Pitts says "While useful no doubt to the medical practitioner, tell the dentist singularly little." May I make the obvious suggestion that perhaps the latter does not always understand the reports? Their treatment of the lesion sometimes suggests this. For some reason Mr. Pitts thinks that radiologists do not hear the post-extractive findings in patients they have radiographed. He would be very surprised to know how much the radiologist is told, but may I here suggest that the information supplied is not always technically accurate. In my article in the *British Medical Journal* already quoted will be seen a radiogram (No. 9) which show a bulbous hypercementosis of the roots of a molar tooth with definite evidence of septic erosion of the mandible around. This tooth I reported to be septic. The dental surgeon who, in attempting to extract the tooth broke off the crown and left in the septic roots, told the patient that I had made a mistake and that "the tooth was sound otherwise it would have come out easily." My reputation was not re-established with the patient and no further treatment was given, in spite of a toxic arthritis, until the patient had been persuaded with much difficulty to see another dentist, when the septic roots were removed.

The leading article in THE LANCET of July 12th states:—

"It has become a common practice among doctors to send patients to have the teeth radiographed. If the radiograms and the reports which accompany them seem to suggest the existence of infection in the teeth, then the patient is referred to a dentist for the appropriate treatment. This order of procedure has brought with it some unhappy results."

In my experience the "unhappy results" are seen where the dental surgeon has previously taken his own radiographs and has excluded a second opinion which would have supported him in carrying out essential extractions. Radiologists frequently see patients upon whose teeth much time and money have been spent in gold-filling and crowning, and find that many of these teeth show definite evidence of apical sepsis. One can readily imagine that neither the patient nor the dentist is pleased with such a report and that the dentist, as your leader states, "generally prefers to make his own interpretation of them." It has been my experience that an attempt to parry the "unhappy result" is made by adversely criticising the report, telling the patient the radiographs are taken at the wrong angle, taking more radiographs and then ignoring the radiologist's report. Mr. Pitts says "the usual reports obtained from radiologists . . . follow a stereotyped line. They often contain inaccuracies and reveal clearly that the writers of them are ill-acquainted with the elements of the anatomy and pathology of the teeth and jaws." I see no reason why medical men should all be so ignorant of this branch of medicine.

Mr. Pitts's recital of recriminations is pathetic and most readers will agree with his statement that "recriminations of this sort are not very helpful," particularly when they learn that these are among the fallacies which will be found illustrated and described (perhaps in the first instance) in the article to which I have referred. When referring to these fallacies, I stated that—

"the errors in dental radiographic diagnosis may be due to (1) faulty photographic and radiographic technique, (2) misrepresentation of the radiograph due to (*a*) lack of experience in interpreting radiographic shadows, (*b*) lack of knowledge of general anatomy and pathology. As

regards (*b*) there is no question that for the best interpretation of radiographs the observer must have a good knowledge of the normal and pathological anatomy of the part. Most books dealing with the radiography of the teeth instance the interpretation of the mental and palatine foramina and loculi of the maxillary antrum as areas of peri-apical absorption, so that these mistakes are hardly likely to be repeated except by the beginner; even if they are the worst that can happen is the sacrifice of one or perhaps two sound teeth. The result of the wide knowledge of the faulty interpretation of these foramina has no doubt been responsible for the much more grave error which is brought to one's notice from time to time—that is, the interpretation of a definite peri-apical absorption as a normal foramen or sinus. It would seem that the larger the cyst the greater possibility is there of it being interpreted as a shadow of the antrum. This is of great importance because the systemic disease from which the patient is suffering continues or increases in severity as the suspected cause has been overlooked and allowed to remain—there being no local signs apparent to the patient or the clinical observer."

In Mr. Henry's article in THE LANCET of July 5th he states that the antrum "extends sometimes as far forward as the lateral incisor, and is often mistaken for an area of pathological destruction, especially when septa dividing it into loculi are present." Yet Mr. Pitts says, referring to a cyst involving the upper lateral incisor which had been mistaken for the antrum, "Though a very elementary knowledge of the anatomy of the jaws should have made it clear that the antrum does not extend to the incisor region." Here we have the opinion of two men "who have knowledge of the structure of the teeth and jaws" not quite agreeing with one another. Members of the medical profession recognise the usefulness o the independent opinion and the right of the patien to obtain it, and will not lightly accept any treatmen from members of their own or allied professions whic is opposed to it.

I am, Sir, yours faithfully,

JAMES F. BRAILSFORD, M.D.

Birmingham, August 2nd, 1930.

THE PROPER STRAPPING OF THE CHEST.

To the Editor of THE LANCET.

SIR,—Referring to Dr. Rudolf's remarks in you issue of July 26th (p. 214), I fully recognise th advisability of having the expiration as full as possibl while the strapping is being applied, but I generall find the shallowness of the breathing caused by th acute pain in inspiration, combined with the pressur of the straps when applied in the manner directed quite sufficient for the purpose. Certainly the strap should run horizontally though, in the female, whe the breast is large, this is difficult. Thankin Dr. Rudolf for his comments,

I am, Sir, yours faithfully,

CHARLES W. CHAPMAN.

London, W., August 2nd, 1930.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS.

PROROGATION OF PARLIAMENT.

PARLIAMENT was prorogued on Friday, August 1st, until Tuesday, Oct. 28th next. Among the Acts which received the Royal Assent were the Appropriation Act; the Finance Act; the Workmen's Compensation (Silicosis and Asbestosis) Act; the Illegitimate Children (Scotland) Act; the Education (Scotland) Act; the Adoption of Children (Scotland) Act; the Housing Act; the Housing (Scotland) Act, and the Road Traffic Act.

PHYSIQUE AND HEALTH OF THE ARMY.

On Wednesday, July 30th, the House of Commons considered the Civil Estimates and the Estimates for Revenue Departments on Report.

On a vote of £879,000 for the Expenses of the War Office,

Lieut.-Colonel WINDSOR-CLIVE moved to reduce the vote by £100. He said that when the Secretary of State for War introduced the Army estimates earlier in the year he revealed the disquieting information that the Army was 10,000 men under establishment owing to the serious falling off in recruits. Before the House separated for the summer recess it was right that they should know whether there had been any improvement in the situation, and what steps were being taken to remedy the situation.

Lieut.-Colonel HENEAGE seconded the motion for the reduction of the vote.

Mr. T. SHAW (Secretary of State for War) said that the War Office was not faced with any problem so far as the number of men offering themselves was concerned. Overwhelming numbers offered themselves for recruitment, but the problem was to get men who were physically fit. The appalling fact was that something like 61 per cent. of those who offered themselves had a reduced standard of height, chest measurement, and dental requirement. That fact ought to induce every Member of the House to do his best to tackle this problem of national physique, because if the race deteriorated no army in the world could sav us from going down.

Earl WINTERTON asked if our Army standard wa not one of the highest in the world.

Mr. SHAW said that might be so, but he was nc at the moment concerned with other countrie During the nine months of the present year 19,21 recruits were taken in. The last month showed a increase over the previous figures, but compare with the numbers who had offered themselves thi number was small. Probably the war and the limita tion in the number of births during that period migh be responsible to some extent for the present situa tion. He thought, however, that it was right t assume that there were millions of men in the countr who did not believe in the Army; they would neve join it voluntarily, and would only take up arms i a grave national emergency. He would speak wit the utmost plainness. The present Governmen would not be responsible for attempting either t reduce the unemployment benefit or to make it mor difficult to get it, because recruits were not comin into the Army. He thought that the question c unemployment pay had relatively little to do wit whether a man offered himself for the Army or not He did not doubt that the peace propaganda had tremendous effect in that direction. That was inevit able, and again the Government could not be asked for the sake of recruiting, to deviate one inch fron their peace policy, or from the principles which the had always declared in regard to peace. He saw n need for panic in regard to the recruiting questio but he agreed that the problem had to be tackle The medical side of the service was understaffe Judging from the information he had received fror reports and data kindly given to him by some of th distinguished men in the medical profession it wa quite evident that that was the case, and the reaso he was told was that the terms were not good enoug

Sir L. WORTHINGTON-EVANS said that he mus warn Mr. Shaw that he must not take consolatio from the idea that he was going to get quickly better type of recruit than was coming forward a the present moment. When he had dealt with th

public health side, and removed some of the underlying causes of ill-health among the population, there might be an improvement, but that would not affect recruiting next year or the year after. What they had to do was to maintain each year, not waiting for a longer period, the numbers of recruits going into the Army.

THE STANDARD OF PHYSICAL FITNESS.

Dr. VERNON DAVIES said that the fact that, although the height standard for the Army was now only 5 feet 2 inches, 61 per cent. of the candidates failed to reach the physical standard, showed that there were in the country to-day a very large number of young men who could not be described as physically fit. He (Dr. Davies) would not suggest that any one should be taken into the Army who was not organically sound, but he wondered whether the test could not be made a little lighter in respect to height, chest measurement, or dental requirements. Many of these men had perhaps been brought up in circumstances of great poverty, under slum conditions, and had not had any chance to live a healthy life in the open air with plenty of good food. If they had that chance they might develop physically and become really good strong healthy men, a credit to themselves and the country. The point about which he (Dr. Davies) was principally concerned was the shortage of medical officers. The Secretary of State for War had informed him that at present the shortage amounted to 140. It was no use having an Army, however small, unless it was healthy, and the only way to secure that was by having a sufficient and efficient medical staff. Mr. Shaw had indicated the vital point—namely, money. The medical man was worthy of his hire. More and more medical men every year were being attracted into the public medical services which offered very great inducements to the best type of man. A hospital medical officer got £600 and a senior medical officer from £750 to £1000. A medical officer to a port sanitary authority was offered £800, a district officer for tuberculosis £750 a year, and the medical superintendent of an institution got from £750 to £1000. The best men were taking up these appointments and the Army was suffering accordingly. If the Army offered sufficiently good terms it would get the medical officers it required. There was another method. The Government employed a large number of medical men in the various public departments. Would it not be possible to arrange that any medical man who had been in one of the services should have a preferential claim to any appointment in the Government Medical Service or under a municipality? The Secretary for War would not have to ask the Chancellor of the Exchequer for very much more money. The position was serious, and it was an urgent necessity that the Secretary of State should see that the medical services of the Army were recruited up to their proper strength.

The motion to reduce the vote was negatived without a division.

HOUSE OF COMMONS.

WEDNESDAY, JULY 30TH.

Tuberculosis in the Navy.

Dr. VERNON DAVIES asked the First Lord of the Admiralty if there had been any increase in recent months in the percentage of cases of tuberculosis which had been granted pensions on account of attributability to the conditions of service.—Mr. ALEXANDER replied: During the past six months 70 per cent. of those invalided for tuberculosis have been granted attributable pensions. This compares with 68 per cent. in the case of those invalided during the year 1929.

Sick Berth Arrangements at Plymouth Naval Hospital.

Mr. HORE-BELISHA asked the First Lord of the Admiralty whether his attention had been drawn to the system of summer leave during the summer leave period (August 1st to 22nd) for the sick-berth staff of the Royal Naval Hospital, Plymouth; and whether, seeing that, owing to shortage of labour, some of the staff would have to be continuously on duty for 13½ hours per day with a possibility of a further four hours' night watch in the event of an accident or serious case being received in the hospital, he would consider whether better arrangements could be made.—Mr. AMMON (Parliamentary Secretary to the Admiralty) replied: Owing to the exigencies of fleet requirements the sick-berth staff of the Royal Naval Hospital, Plymouth, is temporarily short of the authorised numbers. It is also inevitable that during long leave extra work falls on ratings who are not on leave, but no member of the staff is continuously on duty for as long as 13½ hours.

Medical Services in India.

Lieut.-Colonel FREMANTLE asked the Secretary of State for India when he expected to have the views of the Government of India as to the proposed formation of an Indian medical council, and as to the admission to the Indian Medical Service of candidates not holding qualifications recognised by the General Medical Council; and whether, in view of the hardship caused to students now becoming qualified in India, who were thereby losing the advantages of British registration, and the importance of these matters to the welfare of Indians and Europeans in India, and in order to secure its earliest consideration by parties and persons interested, he would publish the reply without delay.—Mr. WEDGWOOD BENN replied: I have not heard when the Government of India expect to be in a position to send me their views, but I have no doubt that they will deal with the matter as expeditiously as possible. I cannot undertake to publish the reply of the Government of India before I have seen it, but I will bear the hon. Member's suggestion in mind.

Laboratory Diagnostic Service for Insured Persons.

Dr. VERNON DAVIES asked the Minister of Health if he was aware that Section 4 of the National Health Insurance Act, 1928, which precluded insurance committees from making grants unless the Minister was satisfied that they were of an eleemosynary character, would abolish next December the laboratory diagnostic service of the Lancashire insurance committee which since 1926 had provided out of local funds a free laboratory diagnostic service for 800,000 insured persons in Lancashire at a cost of less than one farthing per head; and, in view of the importance of such a service to the public health, would he delete the word eleemosynary from Section 4 above mentioned.

Mr. RAMSBOTHAM asked the Minister of Health whether he was aware that, under Section 4 of the National Health Insurance Act, 1928, the Lancashire insurance committee was now precluded from making grants necessary for the continuance of the laboratory diagnostic services in Lancashire; and whether, seeing that the entire community was in favour of such grants being made in view of the valuable work carried out by these services, he proposed to introduce legislation at an early date to alter the law so as to leave the making of grants within the unfettered judgment of the Minister of Health.—Mr. GREENWOOD replied: I am aware that the National Health Insurance Act passed in the late Parliament will produce the effect to which the hon. Members refer. Alternative means of securing services of this character have been suggested to representatives of the committee, but I cannot undertake to propose an amendment of the law on the point.

Working Days Lost Through Sickness.

Mr. DAGGAR asked the Minister of Health the number of working days lost through sickness for each of the years 1921 to 1929 inclusive.—Mr. GREENWOOD replied: I can only give particulars with regard to persons insured under the National Health Insurance Acts. The following Table, which refers to England and Wales, shows the approximate number of weeks for which sickness and disablement benefits were paid under the National Health Insurance Acts during each of the years from 1921 to 1929:—

Year.	Million weeks.	Year.	Million weeks.
1921	19	1926	28¼
1922	19½	1927	30½
1923	20½	1928	26¾*
1924	23¼	1929	29½
1925	25		

* As from Jan. 2nd, 1928, the age at which sickness and disablement benefit ceased to be payable was reduced from 70 to 65.

THURSDAY, JULY 31ST.

Accidents in Demolition Work.

Mr. DAY asked the Home Secretary whether his attention had been called to several recent accidents to workmen caused by the demolition of old buildings; and whether he would consider strengthening the existing law or the

protection of workmen engaged on such work.—Mr. CLYNES replied: I do not know to what accidents the hon. Member specially refers, but a number of accidents to persons employed in the work of demolition have come to the notice of the Factory Department during recent months. The present Factory Act provides only for the protection of those employed in construction or structural repair of buildings, but it is proposed in the Factories Bill to include demolition.

Mental Treatment.

Mr. ROBERT RICHARDSON asked the Minister of Health whether, in accordance with the suggestion of his Parliamentary Secretary, made in response to the wishes of the Standing Committee on the Mental Treatment Bill, certain places would be set apart to give separate accommodation to voluntary boarders; how many of the hospitals which had hitherto been poor-law infirmaries will be utilised for that purpose, so that those who had voluntarily submitted themselves to treatment should not be housed in the same institutions as the certified; and how many hospitals (particularising general or mental) had started out-patient clinics for mental cases.—Mr. GREENWOOD replied: I would remind my hon. friend that the Mental Treatment Bill only received the Royal Assent on the 10th of this month, and does not come into operation until Jan. 1st, 1931. The Board of Control have already conferred with representatives of the local authorities in regard to some of the more important provisions of the Act; but until local authorities have had a reasonable opportunity of considering and determining the steps to be taken in their areas when the Act comes into operation, it is not possible to give the information asked for in this question.

Mr. RICHARDSON asked the Minister of Health what progress had been made in the drafting of the Bill to do away with the differentiation hitherto existing in the procedure of certification in the case of the so-called pauper as compared with the private patient.—Mr. GREENWOOD replied: In the course of the consideration of the recommendations of the Royal Commission notes were prepared on the clauses that would be required to effect an assimilation of the procedure for the certification of rate-aided and private mental patients. But no steps have been taken towards the drafting of a Bill because it is not practicable at present to undertake further lunacy legislation.

Mr. RICHARDSON: Was not a promise made to do this when the Bill was in Committee?

Mr. GREENWOOD: No; I said that we were obtaining all the evidence, but I held out no hope of further legislation.

Chemists and Health Insurance Prescriptions.

Mr. GOULD asked the Minister of Health whether, with regard to the report received from the Somerset health insurance committee, in which it was stated that certain chemists had been dispensing in a very lax way under the National Health Insurance Act, and that in one case a deficiency of 69 per cent. of the drugs as prescribed by the medical practitioner was dispensed to the patient, he would say what action he proposed to take in this matter.—Mr. GREENWOOD replied: The report which I understand that my hon. friend has in mind was received yesterday, and any case of failure to comply with the terms of service applicable to insurance chemists will be dealt with in due course in accordance with the Medical Benefit Regulations.

Mr. GOULD: As this report has been given considerable publicity in the Press, and has left a very bad impression in the minds of the patients in regard to the quality of the dispensing, will the right hon. gentleman consider the report and take action in regard to those who maladminister the Act?

Mr. GREENWOOD: There is no delay on my part. There is a definite procedure to be followed under the Regulations in regard to my intervention, but I am afraid that point has not been reached.

Home for Mental Defectives.

Mr. THOMAS WILLIAMS asked the Minister of Health whether he had yet sanctioned the purchase of Brandonburton Hall by the East Riding (Yorks) County Council as a home for mental defectives; and, if not, before so doing, if he would take into consideration the unsatisfactory situation of this hall and the fact that the site was only 11 feet above sea-level.—Mr. GREENWOOD replied: I have already given provisional approval to the proposal made jointly by the East Riding Council County and York City Council to purchase Brandonburton Hall and 98 acres of land for mental deficiency purposes. The estate was inspected on behalf of the Board of Control who are satisfied that it is suitable for the purpose in view. Such inquiry as I have been able to make in the time available does not support the statements in the latter part of the question.

Patent Medicine Duties.

Mr. LEIF JONES asked the Chancellor of the Exchequer the annual sum received from patent medicine duties; he was aware that the Board of Customs and Excise ha granted exemption from such duty to proprietors of pater medicines in cases where the formula was disclosed and n proprietary right to the preparation was claimed, notwit standing the fact that such proprietors had in the pa advertised and were still advertising that their preparatio prevented or cured illness; and what was the loss of reven due to this exemption.—Mr. SNOWDEN replied: The n amount of medicine stamp duty received in the year end March 31st, 1930, was approximately £1,834,200. Figur for the previous ten financial years may be found in Table III page 11, of the twentieth report of the Commissioners Customs and Excise. (Command paper 3435.) As regar the second part of the question, there is a statutory exem tion from the duty in favour of "known, admitted ar approved" remedies, when sold by duly qualified doctor chemists or druggists, in which no proprietary right claimed, and claims for such exemption are admitted pr vided that a definite and complete statement of the actu ingredients—i.e., the full formula with proportions—and statement that no proprietary rights are claimed in t preparation of the medicine are printed in a legible ar conspicuous manner on all labels, cartons, &c. Followi the decision of the courts in the case of Farmer *v.* Gl Jones in 1903 exemption has not been refused on the grou that known, admitted, and approved remedies have be recommended for the prevention or cure of illness. T cost of this exemption cannot be stated.

FRIDAY, AUGUST 1ST.

Medical Examination of Canadian Emigrants.

The Earl of DALKEITH asked the Secretary of State f Dominion Affairs if his attention had been called to cas in which would-be Scottish emigrants to Canada had so up all they possessed, been passed as fit by medical m in this country, had been rejected at the port of arrival, a returned to Scotland in a state of destitution; and wheth he would consider, in conjunction with the Canadian auth rities, some better system of supervision and control, which there should be a medical authority on this si who had the definite responsibility of saying whether person was or was not fit to emigrate.—Mr. THOMAS replie In order to prevent as far as possible the occurrence of cas of the description referred to by the noble lord all migra from the United Kingdom to Canada are medically examin in this country prior to their departure by a medical offic appointed by the Canadian Government. Under t Canadian immigration law a final medical inspection tak place on the arrival of a migrant in Canada, and in the ve great majority of cases the preliminary medical examinati is confirmed. In a few exceptional cases, however, genera through changes which have taken place since the preli nary medical examination, migrants are refused admissi to Canada as a result of this final medical examinatio but I am satisfied that the Canadian authorities take possible steps to prevent the occurrence of cases of t description.

EAST SUFFOLK AND IPSWICH HOSPITAL.—La year 4721 in-patients were treated to a conclusion; £3 4*s.* 10*d.* each per week their individual total cost w £8 17*s.* 4*d.* Their average stay was 19·22 days. There we 18,222 new out-patients, who made 81,462 attendanc The income—£54,277—was a record; the contributo scheme produced just over £31,000, an increase of ov £1500. The patients' breakfast hour has been altered fr 6 A.M. to 8 A.M.

NOTTINGHAMSHIRE ISOLATION HOSPITALS.—T public health committee of the Nottinghamshire cou council reports that the hospital accommodation the treatment of infectious diseases, other than small-p is sufficient for little more than one-third of the popu tion of the county, and that not less than 200 additio beds are required. They therefore recommend the erecti of one large central hospital of 200 beds. The proporti of the population for which there is no satisfactory sm pox accommodation approaches a quarter of a milli and it is recommended that not fewer than a further beds should be provided, with faculty for extension. I further suggested that all the arrangements for the treatme of infectious disease should be unified, and that the cou should be constituted as one isolation hospital area, wh involves the transfer to the county council of all existi local isolation hospitals. The recommendations were adopt and a scheme is to be prepared for carrying them out.

MATERNAL MORTALITY AND MORBIDITY.

INTERIM REPORT OF DEPARTMENTAL COMMITTEE OF THE MINISTRY OF HEALTH.[1]

THREE years ago Mr. Neville Chamberlain, then Minister of Health, appointed a Departmental Committee to advise upon the application to maternal mortality and morbidity of the medical and surgical knowledge at present available, and to inquire into the needs and direction of further research work. Sir George Newman was made chairman and Dr. Margaret Hogarth secretary, the other members being Prof. F. J. Browne, Dame Janet M. Campbell, Dr. Ethel Cassie, Dr. Leonard Colebrook, Prof. Archibald Donald, Dr. C. E. S. Flemming, Sir Walter Fletcher, Dr. Harold Kerr, Dr. W. H. F. Oxley, Prof. Miles H. Phillips, Dr. C. E. Tangye, and Dr. O. L. V. S. de Wesselow. Owing to illness Dr. Margaret Hogarth was unable to undertake the secretaryship, which devolved on Dr. Jane H. Turnbull. This committee has now submitted an interim report. After a brief introduction the chapters are concerned with a report of the maternal death investigation, abortion in relation to maternal mortality, puerperal sepsis, antenatal care, the use of anæsthetics and analgesics in obstetric practice, medical education in obstetrics, a report on a national maternity service, and conclusions and recommendations. Appendices include reports from the Royal College of Physicians, from the British College of Obstetricians and Gynæcologists, and from a subcommittee of the British Medical Association on anæsthetics in confinements; memoranda on the sterilisation of the hands and on the need for bacteriological services in the control of puerperal infections, by Dr. Leonard Colebrook and Dr. F. Griffith, and a memorandum on antenatal clinics; and a copy of the death inquiry form of the Maternal Mortality Committee.

One of the most important sections of the publication is the

Report on Maternal Death Investigation.

A form of inquiry was drawn up by the committee, and the medical officer of health of the appropriate local authority was invited to be responsible for the completion of the forms. It was suggested by the Ministry that a consultant or a specially qualified practitioner should be nominated to assist the medical officer of health in cases of unusual difficulty, and in some areas this suggestion has been adopted.

The preliminary scrutiny and classification of the forms on lines laid down by the committee were entrusted to two medical examiners appointed by the committee for this purpose—Mr. G. F. Gibberd, obstetrical and gynæcological registrar, Guy's Hospital, and Mr. Arnold Walker, assistant obstetric surgeon, the City of London Maternity Hospital. The committee express appreciation of the accuracy, industry, and good judgment with which they have carried out the onerous and difficult task of preparing the records, of which 3079 were received between November, 1928, and April 30th, 1930. It is estimated that about two-thirds of all the maternal deaths in England and Wales are now coming before the notice of the committee. In this interim report the first 2000 cases only are considered.

[1] H.M. Stationery Office. 1930. Pp. 151. 2s.

The analysis made of these cases has been purely clinical and administrative. They have been divided into two classes—a first group comprising deaths directly due to pregnancy and childbearing (including abortion and ectopic gestation) and numbering in all 1596, and a second group comprising deaths due to an independent disease, concurrent with pregnancy or childbirth, in which childbearing contributed to or accelerated death or was present merely as an incident. In this group there were 404.

DEATHS DIRECTLY DUE TO CHILDBEARING.

The 1596 deaths attributed directly to childbearing have been divided into the following subclasses, which have been based on clinical rather than pathological causes of death.

TABLE I.

		Per cent.
1. Sepsis	616	38·6
2. Eclampsia	218	13·6
3. Operative shock, &c.	145	9·0
4. Antepartum hæmorrhage	125	7·8
5. Postpartum hæmorrhage	92	5·7
6. Other toxæmias, including chorea and mania	99	6·2
7. Embolism	113	7·0
8. Abortion	168	10·5
9. Extra-uterine gestation	20	1·2
Total	1596	

These figures may be studied in connexion with the following table from the Registrar-General's Returns for 1928, though the groups do not and cannot exactly correspond. There is sufficiently close correspondence in the percentages to suggest that the deaths investigated by the committee are fairly representative of the whole number occurring in England and Wales.

TABLE II.—CAUSES OF DEATH AS RECORDED BY REGISTRAR-GENERAL IN 1928.

		Per cent.
Abortion	77	2·60*
Ectopic (extra-uterine) gestation	86	2·90
Other accidents of pregnancy	106	3·60
Puerperal hæmorrhage	331	11·30
Other accidents of childbirth	331	11·30
Puerperal sepsis	1184	40·50
Puerperal phlegmasia alba dolens not returned as septic	31	1·00
Puerperal embolism and sudden death	188	6·40
Puerperal albuminuria and convulsions	557	19·00
Childbirth not assignable to other headings	21	0·72
Puerperal diseases of the breast	8	0·27
Total	2920	

* Other than those due to sepsis and excluding criminal abortion.

In some instances, in view of all the information at its disposal, the committee has thought fit to assign the death to some cause other than the one entered on the death certificate.

Certain clinical points of interest have emerged from the reports.

Sepsis.—The 616 deaths from sepsis have been divided into three classes: (1) Sepsis following ordinary normal labour (294 cases); (2) sepsis following delivery by low forceps, labour being otherwise normal (47 cases); and (3) sepsis following complicated labour (275 cases). Classes (2) and (3) have been differentiated because the frequency with which delivery is effected in private practice by means of the forceps is such that the committee considered that it would be inaccurate to classify all such cases as complicated labour. In all the cases included in class (2) there seemed to be no particular reason for the operation beyond slight delay during the second stage of labour. In the majority of the deaths which followed normal labour there was no positive evidence of any mismanagement during delivery, but the records are not always explicit, and at some stage in many of these cases there is likely to have been some failure to exercise due care which was ultimately responsible for a fatal issue.

Amongst the 616 deaths from sepsis the nature of the antiseptic used was the subject of investigation. In 305

cases lysol alone was used, in 92 cases mercury preparations, and in 219 cases other antiseptics (or unstated). In few of the reports on fatal cases of sepsis have the scheduled questions under "disinfection" have been answered in detail. Serious lack of adequate antiseptic precautions—whether due to ineffective antiseptic solutions or to carelessness in utilising antiseptics—is held to account for the morbidity in many of the cases. The whole question of the adequate disinfection of the hands and instruments of the professional attendants as well as of the surroundings and person of the patient, is one which deserves, and indeed necessitates, far more attention than it apparently receives.

Certain other features of the deaths attributed to sepsis are of interest. For example, the day of onset of pyrexia was recorded in 544 cases, and in 66 per cent. of these it was observed within the first three days; this confirms the general impression that patients who escape a rise of temperature during the first three days are less likely to do badly. The duration of the illness was noted in 607 cases. It was under one week in 276, from one to two weeks in 182, and longer than two weeks in 149. Here again the findings confirm the impressions of most doctors. Another observation, however, will be a surprise to some practitioners. The duration of labour was over 24 hours in only 97 cases out of 307 in which a note was made on the point. It appears from these figures that prolonged labour is not in itself dangerous, and that patients and their friends should be educated to believe this.

Eclampsia.—Under this heading are included all cases of toxæmia in which convulsions or fits occurred. They numbered 218. In 105 cases the urine was tested with some degree of regularity. In 43 of these no albumin was found, but as the date of the last examination of urine was given in very few cases, the conclusion that albumin was in fact absent until the onset of symptoms cannot fairly be drawn. In 62 albumin was found. Of these, very few received treatment in accordance with the best modern practice and in 41 treatment was definitely deficient. In 113—i.e., over half the cases—the urine was either not tested at all or was tested only occasionally. In only 23 cases is there a record of blood pressure having been taken before the onset of fits.

The committee consider that eclampsia is almost entirely a preventable disease, provided (*a*) that urine and blood pressure tests are made regularly and with sufficient frequency throughout pregnancy, and (*b*) that adequate and prompt treatment is carried out should an abnormality arise. In this series 51·7 per cent. of the deaths from eclampsia are attributed primarily to non-detection of the albuminuria, and the committee hold that efficient antenatal examination would probably have enabled the fatal result to be avoided. Amongst the cases where albumin was detected, the committee were impressed by the comparatively frequent absence of competent treatment and particularly by the failure to secure admission to hospital. Only in 21 out of 218 cases was the treatment really satisfactory. The futility of attempting to treat a pregnant woman with albuminuria in her own home, where she has her household duties always before her, is emphasised. The committee consider that the provision of more hospital beds for antenatal observation and treatment of such patients would save much morbidity and many lives every year. Information as to methods of treatment adopted was not sufficient to enable any conclusions to be drawn. The committee express surprise, however, to find that accouchement forcé is still practised in the treatment of cases of eclampsia and of antepartum hæmorrhage.

Ante- and Post-partum Hæmorrhage.—125 cases died from antepartum and 92 from postpartum hæmorrhage. In the vast majority of cases there had been a warning hæmorrhage some days (often some weeks) before the fatal hæmorrhage, and had this been heeded, and the patient removed to suitable surroundings, the fatal result might well have been avoided in many cases. Usually the failure to take heed lay with the patient—in a few cases the doctor or midwife had considered the premonitory bleeding of no importance, and in some cases, although the potential seriousness had been recognised, institutional treatment was not available. In cases of antepartum hæmorrhage treated in the patient's own home, the comparative rarity with which injections of saline solution were given by intravenous or even subcutaneous methods or administered per rectum is held to be significant. In no case of postpartum hæmorrhage reviewed was a blood transfusion given, and in only a small proportion was subcutaneous, intravenous (10 cases), or rectal (20 cases) saline used. Thus in 62 cases no attempt whatever was made to replace body fluids except by the mouth.

Brief notes are given in respect of the deaths due to other toxæmias, embolism, abortion, extra-uterine gestation. The committee consider that many of the 112 deaths following Cæsarean section could have been avoided had proper antenatal care and foresight during labour been available, or had the operation been performed before the birth canal had become infected.

DEATHS NOT PRIMARILY DUE TO PREGNANCY.

Out of the total of 2000 deaths, 404 were returned as attributable to concurrent disease associated with childbirth as follows :—

TABLE III.—INCIDENTAL DEATHS.

Lung diseases (not tuberculosis)	153
Heart disease	98
Chronic renal disease	40
Pulmonary tuberculosis	26
Cerebral hæmorrhage	18
Scarlet fever	4
Unclassified	65
Total	404

The committee were impressed by the general lack of facilities for adequate treatment and management during pregnancy and labour of a woman who is seriously ill with intercurrent disease. In heart disease, in pulmonary tuberculosis, and in chronic renal disease there is an urgent need for accommodation in institutions which would require a medical staff competent in obstetrics as well as general medicine.

The "Primary Avoidable Factor."

The committee have carefully analysed all cases of deaths directly due to childbearing, with the exception of those due to abortion and ectopic gestation, with a view to ascertaining whether death was inevitable, or might have been avoided in more fortunate circumstances. In this connexion the difficulty of correct interpretation by the committee of the information given in the reports has had to be faced. They have, however, felt it to be their duty to note, in every case in which the available information, after being carefully considered, appeared to warrant it, a "primary avoidable factor" in the train of events which led up to the fatal result.

In considering these cases the committee have not had in mind an ideal procedure totally impracticable at the present time in domestic midwifery. They have adopted for convenience a common-sense standard which, though arbitrary, they consider should be attainable with the present personnel and under existing general social conditions, at any rate in areas within reach of consultant and hospital services. It is on this agreed standard (set out in the report) that the records have been analysed.

In summarising the conclusions with regard to the primary avoidable factor, the committee have been forced to use a numerical method because it seems to be the only one that lends itself to the task, and not because they think there is anything approaching mathematical accuracy in their conclusions. They are anxious to emphasise that wherever a figure is quoted in the following summary, it is meant to be a convenient index of a matter of opinion, rather than a precise observation on a mathematical certainty. The committee have made a broad general analysis of the deaths due to pregnancy or childbearing with a view to the discovery of a "primary avoidable factor," with the following result :—

Group 1. Cases showing a primary avoidable factor	6
,, 2. Cases in which no departure from established practice having a causal relationship to the death has been found	6
,, 3. Cases not strictly relevant to this part of the investigation—viz., abortion and extra-uterine gestation	1
,, 4. Cases in which the information was insufficient	1
Total	15

In other words, the committee find as a result of inquiry into these deaths that in 39 per cent. of the total number occurring as the direct result of child

irth the data obtainable indicate a primary avoidable ause. When the "irrelevant" cases and the cases ith insufficient information are excluded the net ercentage of preventable deaths is as high as 48, iat is, nearly half the cases showed a primary voidable factor. These avoidable factors have been ibdivided under four headings: (*a*) omission or iadequacy of antenatal examination, (*b*) error of idgment in the management of the case, (*c*) lack f reasonable facilities, and (*d*) negligence of the atient or her friends.

OMISSION OR INADEQUACY OF ANTENATAL EXAMINATION.

The committee have limited this group to cases iowing complete absence of proper antenatal care. i most of the instances the responsibility rested on ie patient, but it is also evident that the quality of ie supervision given leaves a good deal to be desired. aulty antenatal care was considered to be the rimary avoidable factor in 226 of the 626 cases in his group (36 per cent.). In 157 of these cases the octor or midwife responsible for the care of the atient had failed to make any antenatal examination t all or the patient had given them no opportunity o do so. And in 69 others antenatal examination iled to detect a gross abnormality which must ave been present. These cases are set out in the llowing tables (A and B):—

ERROR OF JUDGMENT.

Such errors of judgment as bear little or no refer-ce to the event of death have not been ascribed as primary avoidable factor.

Errors Attributed to Midwives.—The greatest number of ors which had a direct bearing on the fatal termination the case were naturally attributed to doctors, as on them sts the ultimate responsibility for all conditions showing departure from normal. For this reason it is recognised at deductions based upon a comparison of mortality-es in the practice of doctors and midwives respectively ay be entirely misleading. Not only is the midwife liged in all abnormal cases to send for medical aid, but e is also bound by her rules to refuse to undertake alone ase in which, from the history or from some other indica-n, abnormality appears probable. Thus the midwife s not the same opportunity of exercising an independent dgment, and can always call for assistance when in ubt. The 57 cases where the fatal termination is con-dered to be due primarily to error of judgment on the rt of the midwife were almost entirely cases of contra-ntion of her rules. The small remainder were nearly all amples of gross ignorance, and the midwife was usually und to be much too old for her work.

Errors Attributed to Doctors.—These occurred chiefly in miciliary practice, though there were a few clear instances mismanagement of cases admitted to hospital. In this nnexion regard should be paid to the handicaps under hich the general practitioner works in obstetric cases; he as for long acquiesced more or less unwillingly in this satisfactory position. Surprisingly good results are ten obtained in untoward circumstances, but not infre-ently the doctor attempts the impossible, and the case ds in a tragedy. Again, unless labour is relatively rapid, may find himself pressed by the patient and her relatives expedite delivery, other urgent work may be awaiting m, and there is often a strong temptation to hasten the se, even though he may be conscious that in so doing a eater or less degree of departure from the path of sound idwifery is entailed.

In nearly one-third of the cases classed as errors of dgment on the part of the doctor, the mistake was ematurе application of the forceps. In many of ese delivery was not effected, and the patient was ultimately sent to hospital where incomplete dilatation of the cervix or disproportion was usually found to be present. Other examples of common error are failure to treat a toxæmia of pregnancy, and the neglect of early warning hæmorrhage in placenta prævia.

Error of judgment on the part of the doctor or midwife or hospital was assigned as the primary avoidable factor leading up to the death of the patient in 224 cases (35·7 per cent. of the group of 626 cases), and these cases are analysed in the following table:—

TABLE C.

Errors of judgment.	Doctor	Hospital.	Midwife.	Total
Treatment of severe toxæmias of pregnancy faulty or absent ..	27	9	7	43
Neglect of warning hæmorrhages	17	2	5	24
Improper use of forceps.. ..	41	4	—	45
Faulty treatment of third stage of labour	16	2	9	27
Non-recognition of obstructed labour	8	2	10	20
Gross errors in the prevention or recognition of sepsis	7	2	14	23
Miscellaneous	30	—	12	42
Total	146	21	57	224

LACK OF REASONABLE FACILITIES.

In this class are included cases in which the absence of skilled assistance was the primary cause in the death, cases conducted in abnormal surroundings, such as delivery in a cowshed, instances of women living in remote and isolated situations, and one or two examples of extreme overcrowding. Poverty and uncleanliness, although unfortunate accessory factors, have not, so far as can be ascertained from the reports, borne any direct relation to these deaths.

Lack of reasonable facilities was considered to be the primary avoidable factor in 64 cases. Only a few of the deaths could be attributed to difficulty in obtaining medical assistance of some sort. In 26 cases it was thought that the most important factor leading to the fatal issue was absence of a second doctor to give an anæsthetic. In 13 cases it seemed probable that if the doctor had had a trained assistant, instead of having to rely in a difficulty upon the inadequate help of a totally incompetent relative or friend, the result would have been different. In 25 deaths it was considered that the most important cause leading up to the death lay in the bad surroundings under which the patient was confined.

Absence of hospital beds and of consultant services had undoubtedly been responsible for death in many cases.

NEGLIGENCE OF THE PATIENT AND HER FRIENDS.

In 112 deaths the Committee considered that the most important cause leading up to the death was absence of sensible coöperation on the part of the patient—in the majority of cases amounting to deliberate refusal to carry out advice or to take any reasonable steps to obtain help. In addition to these, there were 109 patients who failed, presumably through ignorance, to submit themselves to antenatal examination, and these have been included under the appropriate heading.

Cases where No Avoidable Cause has been Detected.

There remain 660 deaths, in some of which there was nothing definite in the report to show that the woman had not received attention in accord with the reasonable standard laid down, while in others the failure to attain the standard had no apparent causal relation to the fatal termination. It should be noted that in a large number of cases failure of the Committee to discover an avoidable cause is probably due to deficient information rather than to the absence of such a cause.

Conclusions.

The committee draw certain conclusions from this section of the report. While emphasising the extreme importance of antenatal examinations, they have found evidence of a certain amount of inefficient work which has passed under the guise of "antenatal care." They consider that adequate and satisfactory antenatal care requires as much experience, as much skill and as much diligence as operative midwifery itself, and that every effort should be made to secure effective medical supervision by competent medical practitioners in close touch with actual obstetric work.

Not only have the Committee found evidence of neglect in antenatal diagnosis, but also to a great extent in antenatal treatment. In many instances failure to treat a patient has largely been due to lack of facilities, and the Committee think that great benefit would follow an increase in the number of beds available for such cases in institutions. In relation to serious complications and accidents of labour, the Committee have ample proof of the need for a higher standard of knowledge and skill on the part of the general practitioner, as well as for the provision of consultant services and of an increase number of readily available hospital beds.

While better facilities for blood transfusion wou be highly advantageous, the majority of cases hæmorrhage and obstetric shock can be saved fro death by the immediate replacement of fluid by intr venous or subcutaneous saline solution or other sui able fluid. Saline solution per rectum may be effecti in mild cases, but the fluid is not absorbed by t bowel in cases of severe collapse. The Committe therefore, regard the extended provision of the services as an essential part of any measures tak for the improvement of midwifery work. They loo for substantial improvement in the number of deat from sepsis following abnormal labour. It seems them a reasonable hope that the amount of difficu midwifery performed under unsuitable conditio will steadily decrease, and as a result the number deaths from sepsis in this group will decrease also.

On the other hand, the number of deaths fro sepsis following "normal labour" demands intensi investigation. Failure in efficient antiseptic techniq probably accounts for a considerable number of the cases.

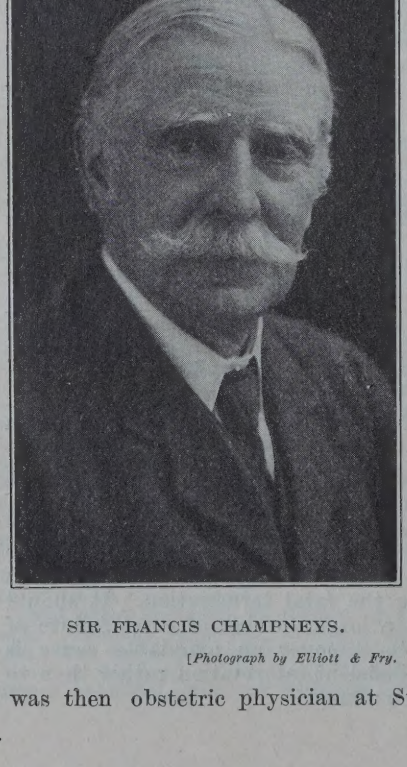
(To be concluded.)

OBITUARY

SIR FRANCIS CHAMPNEYS, Bt., M.D. Oxf., F.R.C.P. Lond.

Sir Francis Champneys, the well-known obstetric physician, died on July 30th at his residence, Littlewood, Nutley, at the age of 82.

Francis Henry Champneys was the second son of the Very Reverend William Champneys, Dean of Lichfield, and was educated at Winchester where he was a scholar, at Brasenose College, Oxford, and at St. Bartholomew's Hospital. At Oxford he obtained a first class in science in 1870, and two years later he was elected Radcliffe Travelling Fellow. Champneys graduated in medicine in 1875, and in the following year obtained the M.R.C.P. Lond. While he held the travelling scholarship he did post-graduate work in Vienna, Leipzig, and Dresden, and in the last city held the post of clinical assistant to the Royal Saxon Lying-in Hospital, thus commencing his successful career as an obstetrician. On returning to London he became assistant to Dr. Matthews Duncan, who was then obstetric physician at St. Bartholomew's Hospital, and was himself made an obstetric tutor the medical college, an appointment which had so influence on his future career. For although in 18 the year he was elected F.R.C.P., Champneys w made obstetric physician at St. George's Hospital, succession to that great and original teacher, Rob Barnes, he was invited to return to St. Bartholomew Hospital on the death of Matthews Duncan, a accepted the invitation. Meanwhile he had be appointed assistant physician to the General Lying Hospital, and found there material which contribut to his wide knowledge of practical obstetrics. As teacher Champneys was fluent and informing in l lectures and clear in his practical demonstratio While he was at St. George's he left the operati side of his department to some extent in the hands the surgical staff, while at St. Bartholomew's t terms of his appointment confined him to midwife His writings are consequently for the most pa concerned with obstetric problems, but when invit by the Harveian Society of London to deliver t Harveian lectures in 1890 he chose for his subje Painful Menstruation. The lectures were afterwa published in THE LANCET, and are noteworthy i the lecturer's discrimination between distress different kinds, ranging from vague discomfort acute localised pain. The general conclusions co cerning dysmenorrhœa in his first lecture show balanced outlook on the psychology of differe types of patient which gives a clue to his success relieving mental as well as physical suffering.



SIR FRANCIS CHAMPNEYS.

[Photograph by Elliott & Fry.

Under the Midwifery Act of 1902 which, af considerable opposition both within and without t medical profession, obtained a place on the Statu book, the Central Midwives Board came in existence, and Champneys was made its first cha man. As is well known, the purpose of the Act w to regulate the practice of women midwives, standardise the education of those who obtained place on the official roll of midwives, and to exerc disciplinary powers such as would prevent t incompetent woman, or woman who failed to obser the regulations of the Act, from maintaining th place on the roll. Champneys held strong vie on the importance of the duties of the Board.

was always sympathetic to the midwives, however, and the fairness and tact with which he managed the proceedings, sometimes difficult and delicate, were acknowledged on all sides, and led to his re-election year by year to the chairman's seat. It is difficult to imagine the Board with any other chairman, for until the illness occurred which ended in his death he was only absent from two Board meetings during the 28 years of his chairmanship. Nor was this his only activity in the administration of professional affairs, for in 1911 he was nominated by the Crown as a member of the General Medical Council; this five years' appointment was twice confirmed, so that Champneys retained his seat on the Council for 15 years. In 1910 he was created a baronet.

Champneys took a keen and active interest in medical societies. He held many official posts in the Obstetrical Society of London, culminating in that of president in the session 1895–96, and communicated much of his work to this society. When it was merged into the Royal Society of Medicine he followed its fortunes with no less interest, and was honoured by being elected president of the last-named society in 1912 and 1913. In 1913 also he acted as president of the Section of Obstetrics and Gynæcology at the International Medical Congress. Naturally his services were sought by examining bodies, and at different times he was an examiner for the universities of Oxford, Cambridge, and London, and for the Conjoint Board. In recent years Sir Francis took a warm interest in the organisation of the British College of Obstetricians and Gynæcologists. He was attracted by the idea when it was first conveyed to him, and gave great help in overcoming the difficulties with which the undertaking was faced. He became a member of the first Council of the College and was elected its first and up to now the only vice-patron.

Apart from his professional activities Champneys was well known in the musical world. Both at school and at college he had been devoted to music, and shortly after his establishment in London he became the centre of a highly musical coterie whose object was the study of church music. He was himself an executant upon several instruments, and the composer of several anthems.

Sir Francis Champneys will be greatly missed in many different circles, and his stimulating personality and wise judgment will long be remembered.

Dr. J. S. Fairbairn writes: "After an association with Sir Francis Champneys of over 25 years, the latter half of them including service together on the Central Midwives Board, I look back on him as an outstanding example of the cultured professional man with a stern sense of public service. He lived up to his high principles and strong convictions, tinged almost with austerity, but without the aggressiveness and love of controversy often associated with them. My acquaintance with him began in his mellower years, when I found an openness of mind and willingness to hear the views of others, and in particular the aspirations of a much younger generation. A concrete instance may best illustrate this aspect of his character. The time was the proposed amalgamation of the medical societies of London into the Royal Society of Medicine, and the occasion an informal discussion thereon following a meeting at his house for another purpose. The union of the Obstetrical with the British Gynæcological Society was mentioned as implicit in this amalgamation, and Champneys once expressed his opposition on the ground that involved great principles underlying the breakaway in the past of the newer from the older society. One of the younger school present pointed out that he and his contemporaries knew nothing of the history of the split and were not prepared to take up the controversies of their predecessors or allow past history to interfere with a movement that seemed otherwise beneficial. Champneys gave us the story and stated his case, but obviously recognised that it had no longer much appeal to those who had not had personal experience of living through the struggle. When the matter came to be discussed later at the Council of the Obstetrical Society and elsewhere, he worked for the amalgamation and became one of the early presidents of the Royal Society of Medicine. Again, in the last three years of his life, when his active professional work was long past, he threw himself wholeheartedly into the scheme for forming a British College of Obstetricians and Gynæcologists and was one of the signatories to its incorporation, because he appreciated the feeling among a younger generation for some body to represent the practitioners and teachers of these subjects. As a final example of his continued interest in work in the hands of a new generation, his response to the request of his friend, the late Sir Clifford Allbutt, to undertake the chairmanship of the examiners in midwifery at the University of Cambridge, may be quoted. He did this for a few years after the war, when well over 70 years of age, and those who acted with him will recollect how he threw himself into the reorganisation of that examination.

His high ideals of public service brought Champneys into touch with many aspects of medical work, but he himself obviously regarded his efforts towards the provision of a body of trained midwives for the country as his chief contribution to the common weal. His interests in this direction began with his appointment to the staff of the General Lying-in Hospital, where the training of women for practice as midwives has always been a prominent feature, and were further developed when he was made chairman of the Midwives Committee of the Obstetrical Society. He constantly referred to the part he had taken in the work of that committee and how he had thereby been brought into conflict with the British Medical Association and General Medical Council. He was thus clearly marked as the chairman of the Central Midwives Board, when constituted by the Midwives Act of 1902, for that body practically took over functions already carried on unofficially by the Midwives Committee of the Obstetrical Society. For 27 years he was annually re-elected by its members as chairman of the Board and, more than any other of its members, was responsible for moulding its procedure and policy. Its early problem was the difficult one of a new and untried body gaining the confidence of the divergent interests represented by the practising midwives it controlled, the general practitioners that came to their aid, the medical officers of health who supervised their practice, and the teachers who had to follow the Board's instructions on training. That the new body succeeded in working smoothly and avoiding serious controversy, even so far as to secure general approval was a remarkable tribute to the sagacity and tact of the man at the wheel. His was no nominal chairmanship, for he was always in touch with the business of the Board and word perfect in his part before each meeting; he was ready to sum up each item on its agenda and had a resolution in draft prepared for discussion. Until he had been over 21 years its chairman he had not missed one of its monthly sessions, and to the last he retained the confidence of its members in his wise counsel.

judicial mind, and practical knowledge of midwifery problems. Nowhere will the death of Sir Francis Champneys be more deeply felt than by the body whose destinies he has guided from the time it came into being."

Sir Francis Champneys was buried at Hampstead Cemetery. A memorial service was held at St. Bartholomew's-the-less on August 2nd. He is succeeded by his only surviving son, Captain Weldon Dalrymple-Champneys, D.M. Oxf., medical officer to the Ministry of Health.

JOHN WALLIS BARRON MASON, M.D. Brux., M.R.C.S. Eng.

Dr. Barron Mason, who died on July 25th, was born in London in 1853, and was educated at Epsom College. From there he went to the Middlesex Hospital, where he won the Broderip scholarship, and qualified in 1875. After holding resident appointments he served as a ship's surgeon for several years, visiting India and the Far East. His father had been in practice at 1, Osnaburgh-terrace, N.W., since Dr. Mason was a small boy, so on returning from the sea he went to live at this address, and after his father's retirement he ran a large general practice there for about 43 years. His health gradually failing, he retired at the end of 1929. He was a well-known and popular figure in the district, and served on the St. Pancras Panel Committee for some years. He leaves a widow, a daughter, and one son, who has succeeded him in the practice, which has now seen three generations of the same family.

JAMES ALLAN GRAY, M.D., F.R.C.P. Edin.

We have to record the death of Dr. J. A. Gray o July 29th. He graduated in arts at Edinburg University in 1872, in medicine in 1876, and receive a gold medal for his M.D. thesis in 1880. His academ career gave the promise of his becoming a consulta physician, and he was elected a Fellow of the Roy College of Physicians of Edinburgh in 1881, but l devoted himself to general practice. He was for period medical officer of health (part time) of t burgh of Leith, then a town of some 75,000 inhab tants. In 1894 the office was made a whole-time on and Dr. Gray retired. He was a man of very distin individuality; quick in perception, ready in arg ment, prompt and adequate in all his profession work. As medical officer of health he had to fa the public health difficulties of the seaport town at time when notification of disease was unknow when infection was still nursed in the general hospita and when sanitation was really in its infancy. Amo other things, he was a master in the gypsy speec and he had come a great deal in contact with t peripatetic gypsies of the North of England. Up last year he was in active practice. He took his f share in the examination boards of the Royal Colleg and was always a welcome companion among h colleagues. His son is Dr. J. D. A. Gray, Liverpool.

Dr. Gray took a keen interest in the Volunteers a retired as surgeon-colonel of the 7th Royal Sco earning the Volunteer Decoration.

MEDICAL NEWS

University of Cambridge.

At recent examinations the following candidates were successful:—

DIPLOMA IN TROPICAL MEDICINE AND HYGIENE (PART II.).

R. J. Dyson, I. A. El-ghamry, M. S. El-Kinani, A. M. Karam, C. O. Karunakaran, J. H. Loots, K. C. K. E. Raja, and W. J. Vickers.

Royal Colleges of Physicians of London and Surgeons of England.

At the Final Examination of the Conjoint Board, held from June 30th to July 22nd, the following candidates were approved in the undermentioned subjects, but are not eligible for diplomas:—

Medicine.—E. F. Adams, Manchester; R. M. Alderton, London; R. Barnes, Manchester; C. R. G. Barrington, Univ. Coll.; J. H. Bartlett, St. Mary's; W. S. Baxter, St. Bart.'s; H. H. W. Bennett, London; G. A. Betts, Birmingham; B. N. Bhandari, Durham; Marjorie E. Birch, Liverpool; Dora E. Brockbank, Royal Free; G. T. W. Cashell, King's Coll.; F. A. Clift, London; L. C. Crane, Manchester; M. J. Cunning, Royal Free; F. M. Day, St. Mary's; S. B. Dimson and G. W. Duncan, Univ. Coll.; J. R. P. Edkins, Manchester; C. F. Evans, Melbourne and London; H. Goldenberg, London; G. J. Griffiths, Westminster; Marjorie K. Hall, Royal Free; H. E. Harding, London; **Honor** E. C. Harvey, Royal Free; W. Hogg, St. Bart.'s; **A.** Jokl, Middlesex; I. J. Keidan, Leeds; G. D. Kersley, St. Bart.'s; S. J. Knight, St. Mary's; E. Lethem, Guy's; B. F. Longbotham, London; P. H. Maal, Amsterdam and Liverpool; D. G. Macdonald, London; F. G. Maitland, St. Mary's; Dorothy Makepeace, King's Coll.; J. T. Mani, Durham; Barbara A. Merlin, Royal Free; W. A. Mirza, Lucknow; H. C. Muirhead, Guy's; Lois M. Munro, Royal Free; Gladys L. Neill, King's Coll.; D. Ockman, Manchester; Doris Onions, Leeds; W. H. Poole, London; J. W. Pugh, Univ. Coll.; J. Rabinovitch, Leeds; Louise Rees and Irene P. Rowlands, Charing Cross; B. Rubinsky, London; S. Ryman, Zürich; R. S. Sandhu, Lahore; W. W. Sargant, St. Mary's; J. Shernovitch, Leeds; Rosalie Shoenberg, Royal Free; D. O. C. Simpson, London; M. Singh, Punjab and Birmingham; Violet Spiller, Royal Free; A. B. Stokes, T. R. Swarup, and G. M. Tickler, King's Coll.; W. J. Tindall, Univ. Coll.; C. Verity and N. S. Walls, Manchester; J. G. Warren and S. I. Weinstein, London; A. M. Weston, Guy's; C. Wright, Univ. Coll.; and C. H. Wrigley, St. Thomas's.

Surgery.—I. S. Acres, London; S. Amir-ud-Din, Edinburgh; R. Barnes, Manchester; D. S. Bateman, St. Thomas's; N. J. Bee, London; J. N. Bhada, Univ. Coll.; B. N. Bhandari, Durham; K. C. Dr. A. F. Voelcker was appointed to represent the College at the celebration in October of the jubilee of the foundation of Mason Science College, Birmingham, and the thirtieth anniversary of the granting of the University charter.

The following candidates, having satisfied the Censor's Board, were admitted Members:—

Philip J. Alpers, Benjamin Barling, Innes A. Brodziak, James W. Brown, Eleanor M. Creak, Philip E. J. Cutting, John Dockray, Mohammed Abdul Aziz El Gammal, John C. Hawksley, Roy H. Howells, Charu Chandra Kapila, Gwash Lal, Edward W. Lindeck, Frederick M. Lipscomb, Florence Louis, Thomas K. S. Lyle, Harry E. Mansell, Dhirendra Chandra Mazumdar, Andrew J. Morland, Santosh Kumar Mukhopadhyay, Margaret G. P. Reed, Edward G. Robertson, Gerald R. A. de M. Rudolf, Ismail Ahmed Sabri, James D. Simpson, Eliot T. O. Slater, John Smith, Bashi Lal Taneja, and John R. H. Towers.

At the same meeting of the Comitia on July 31st licences to practise were conferred upon 141 candidates (115 men and 26 women) who have passed the final examinations of the Conjoint Examining Board. The following are the names and medical schools of the successful candidates:—

Constance E. Allan, Royal Free and Charing Cross; S. G. Allen, L.D.S., London; R. E. Angel, St. Bart.'s; Lily Arratoon, Indiana and Royal Free; J. Aytoun, Middlesex; F. G. Badger, Cardiff and London; W. I. Bain, Cambridge and St. Thomas's; W. L. H. L. Bell, St. George's; S. W. T. Bentall, Oxford and London; A. C. Bhardwaj, Punjab and Guy's; I. Billig, St. Thomas's; W. R. Bion, Oxford and Univ. Coll.; A. N. Birkett, Manchester; S. Bochenek, St. Bart.'s; Kathleen M. Bodkin, Birmingham; B. F. M. Bond, Westminster; F. K. Boston, Cambridge and St. Bart.'s; Julia A. Boyd, Royal Free; L. V. O. Brown, Cambridge and Guy's; A. Buch, St. Mary's; W. R. Burrows, St. Bart.'s; M. L. Bynoe, King's Coll.; E. C. Campbell, Cambridge and St. Mary's; G. F. Carey, Cambridge and St. Thomas's; J. Chamberlain, Guy's; H. M. Chappel, Cambridge and Univ. Coll.; L. Charney, Cape and London; W. F. Church, Cambridge and St. Bart.'s; L. P. Clarke, L.M.S.S.A., St. George's; A. H. Clegg, Leeds; D. H. Collins, M.B., Liverpool; R. V. S. Cooper, M.B. Birmingham; W. C. Cresdee, St. George's; R. M. S. Cross, Cambridge and St. Bart.'s; Elizabeth T. Davies, Westminster; L. S. Davies, Cardiff and Guy's; C. G. S. De Silva, Ceylon and Guy's; C. H. Devin, St. Bart.'s; D. Divine, Cambridge and Guy's; R. H. Dodds, Cambridge and London; J. A. Doherty, Univ. Coll. and Durham; N. R. Donald, Liverpool; Mary G. H. Edwards, St. Mary's; A. Elliott, M.B. Birmingham; M. M. El Mishad, Cairo and Guy's; A. A. G. Flemming, Cambridge and Bristol; G. M. Flemming, St. Bart.'s; E. V. P. Fox, Cambridge and St. Bart.'s; Margaret L. Foxwell, Manchester; P. I. Franks, St. Bart.'s; L. P. Friedman, Univ. Coll.; Lorna M. A. Goulden Bach, Westminster; Mabel E. Grace, Royal Free; C. A. Grant, Cambridge and St. George's; E. R. Greathead, Cambridge and London; G. Hale, Cambridge and St. Thomas's; J. T. P. Handy, Univ. Coll.; R. D. Harding, Oxford and King's Coll.; Eileen E. Harvey, Royal Free; R. M. Harvey, London; Gladys M. Herbert, St. Mary's; Constance M. Hoare, King's Coll.; H. L. Hodgkinson, St. Bart.'s; Laura M. Hollingworth, Univ. Coll.; J. C. de V. Hutchinson, Cape and Guy's; E. B. Jackson, Univ. Coll.; E. J. Javeri, M.B., Bombay and London; G. H. Jennings, Cambridge and St. Mary's; H. B. John, St. Mary's; I. G. Jones, Univ. Coll.; W. D. G. Jones, Guy's; C. R. Kenchington, M.B., Birmingham; P. A. E. Lansle, M.D., Lausanne and London; S. R. Ledger, King's Coll.; J. C. Leedham-Green, Oxford and Middlesex; Edna Lock, King's Coll.; R. F. Lomax, Oxford and Guy's; R. P. Lucas, M.B.,

Bristol; H. O. Lyne, L.D.S., Guy's; Joyce MacInnes, Royal Free; Moyra I. Macnaughton-Jones, Royal Free; F. G. Mailtand, Cambridge and St. Thomas's; H. S. A. Malik, M.B., Bombay and St. Thomas's; P. T. Merlin, M.B., Birmingham; Elizabeth T. Mess and Ruth Milne, Royal Free; Blodwen Morgan and G. D. Morgan, Charing Cross; K. I. Nicholls, Bristol; T. C. Outred, Guy's; G. A. Y. Parker, St. Bart.'s; C. F. L. Patterson, Cambridge and St. George's; G. H. Pearce, Univ. Coll.; R. B. Peckham and N. S. Plummer, Guy's; N. H. L. Ridley, Cambridge and St. Thomas's; R. S. Risk, St. Bart.'s; D. M. Roberts. Cardiff and London; J. M. Robertson and L. K. Robson, Guy's; Helen E. Rodway, Royal Free; A. L. Rowson, Manchester and London; M. H. Salaman, Cambridge and London; F. M. Sandford, St. Thomas's; K. C. Sarkar, M.B., Calcutta and King's Coll.; J. M. Searle, London; T. S. Severs, M.B., Durham; Violet R. Sharp and Dorothy A. Sharpe, Royal Free; C. J. C. Siggers, L.D.S., Guy's; W. W. Simkins, St. St. Mary's; C. H. Sims, Westminster; K. C. S. Skene, Univ. Coll.; M. W. Smith, Manchester; J. Sowerbutts, Cambridge and St. Thomas's; A. A. Staunton, St. Bart.'s; D. J. R. Steen, Cambridge and St. Thomas's; G. V. Steward, Guy's; J. G. Stewart, Westminster; H. M. Strover, M.B., Bristol; H. B. Swift, M.B., Punjab and St. Mary's; K. T. Taskar, M.B., Bombay and London; C. E. Taylor, Cambridge and King's Coll.; M. R. Thomas, Univ. Coll.; K. S. Thompson, London; C. J. L. Thurgar, Univ. Coll.; T. F. Tierney, St. Bart.'s; O. T. Wade, Leeds; W. N. P. Wakeley, King's Coll.; E. C. Watson, St. Mary's; J. C. S. Wells, Univ. Coll.; Margaret E. Williams, Bristol; T. C. Williams, Wales and Univ. Coll.; T. G. Williams, Middlesex; B. Willinsky, M.D., Toronto; Maureen D. Willmott Evans, Royal Free; F. W. Willway, King's Coll.; W. E. Wimberger, M.B., Birmingham; H. A. M. Wintle, St. Thomas's; Barbara E. Woodhead, M.B., Birmingham; and F. C. A. Wright, King's Coll.

The undermentioned diplomas were conferred (jointly with the Royal College of Surgeons) upon the following candidates:—

Diploma in Psychological Medicine.—R. D. Curran, J. W. Fisher, J. Flind, R. N. B. McCord, W. M. McGrath, W. Ogden, D. N. Parfitt, R. Ström-Olsen, V. Vassallo, and A. W. Watt.

Diploma in Laryngology and Otology.—C. A. Amesur, A. B. Berkowitz, E. G. Dermer, A. M. El Hakim, A. El S. Handousa, B. Hiller, I. Kallmeyer, F. T. Land, M. R. Levey, H. Lewis, G. R. Marcano, F. G. Meade, F. Phillips, S. N. Prasad, H. W. Savige, G. S. Seed, and S. K. Sen Gupta.

Diploma in Public Health.—Edith L. I. Abbott, Iris I. G. Adams, H. W. Allen, J. V. Almeyda, G. R. M. Apsey, S. K. Arora, E. R. Boland, M. S. Chadha, S. Dakshinamurty, Edith M. Davies, I. G. Davies, P. T. J. Doss, S. W. Eveson, A. H. Gale, K. K. Goh, Phyllis M. Grainger, A. Hamid, E. B. Jones, B. N. Khanna, N. K. Kumaran, B. K. Lal, B. D. Malhotra, B. D. Mallick, R. Mansoor, H. D. M. L. Murray, W. R. Nash, G. E. B. Payne, S. M. Rahman, G. A. Roche, A. Shafi, J. Spencer, M. P. Srivastava, and V. Whitman.

Diploma in Tropical Medicine and Hygiene.—C. A. Alvarado, T. F. Anderson, W. K. Connell, A. B. Cook, M. K. Kelavkar, E. M. Lourie, D. R. McPherson, F. Marsh, T. H. Nolan, P. K. Rao, C. E. Roberts, R. Shelley, M. Singh, R. G. Spink, T. W. Stephens, Dorothy E. Stewart, Marjorie V. N. Sudds, B. A. Taylor, S. E. Theis, H. G. Timbres, Gladys M. Tullidge, and E. M. Wijerama.

Diploma in Ophthalmic Medicine and Surgery.—Dorothy R. Adams, T. S. Blackiidge, H. P. Chaudhuri, M. A. Contractor, E. R. Cunningham, J. Dadabhoy, D. R. Gawler, L. M. Green, Millicent Hamilton-Johnstone, H. V. Ingram, S. Lal, Laura M. Ligertwood, S. S. Lindsay, L. Mahadevan, T. M. Mansfield, A. B. Rao, C. N. Smith, L. Staz, L. Tarneja, H. Tomkin, T. a'B. Travers, and D. K. Weston.

Royal College of Surgeons of England.

AN Ordinary Meeting of the Council was held on July 31st, with Lord Moynihan, the President, in the chair.

The Honorary Gold Medal of the College was awarded to Mr. R. Lawford Knaggs, F.R.C.S., in appreciation of his services to the Museum, more especially in preparing a catalogue of and revising the Strangeways Collection of specimens illustrating arthritis.—The first Macloghlin Scholarship for medical students was awarded to L. Ilford, King George Hospital.—Res. M.O. £200.
Infants Hospital, Vincent-square, Westminster, S.W.—Two H.P.'s. Each at rate of £75.
King's College Hospital, Denmark-hill, S.E.—Jun. Physician.
Leeds, Herzl Moser Hospital, Leopold-street.—R.M.O. £100.
Liverpool City.—Res. Asst. M.O.'s. £200.
London University, South Kensington, S.W.—William Julius Mickle Fellowship. £200.
Manchester Royal Eye Hospital.—Jun. H.S. £120.
Manchester University.—Demonstrator in Chemical Pathology. £350.
Margate and District New General Hospital.—Res. M.O. £125.
Marseilles, Queen Alexandra Memorial Hospital.—Res. M.O. £250.
Merthyr General Hospital.—Res. H.S. At rate of £150.
Middlesex Hospital, W.—Medical Men interested in Radium Treatment of Malignant Disease.
Nottingham, Hospital for Women.—H.S. At rate of £150.
Nottingham and Midland Eye Infirmary.—Res. H.S. £200.
Oldham Royal Infirmary.—Two H.S.'s to Special Departments. Each at rate of £175.
Plymouth, South Devon and East Cornwall Hospital.—Hon. P. and Hon. Asst. P.
Preston County Borough.—Asst. School M.O. £600.
Richmond, Surrey, Royal Hospital.—Jun. H.S. At rate of £100.
Rochdale Infirmary and Dispensary.—Jun. H.S. £175.
Ryde, Royal Isle of Wight County Hospital.—Two Hon. Anæsthetists.
Southampton County Borough.—Asst. School Dentist. £450.
St. Charles Hospital, Charles-square, Ladbroke-grove, W.—3rd Asst. M.O. £300.
St. Giles' Hospital, Brunswick-square. S.E.—Deputy Med. Supt. £650.
Stockport Education Committee.—Asst. School Doctor. £500.
Saint Mark's Hospital for Cancer, Fistula, &c., City-road, E.C.—Res. Surg. O. At rate of £150.
Salford, Hope Hospital.—Res. Surg. O. £400.
Sheffield Royal Hospital.—Res. Anæsthetist. At rate of £80.
Swansea County Borough, Infectious Diseases Hospital.—Res. M.O. £350.
Walsall Manor Hospital.—Res. Asst. M.O.'s. £200 and £150 respectively.
Warwick County Mental Hospital, Hatton.—Jun. Asst. M.O. £350.
West Ham County Borough.—Deputy M.O.H. £850.
Winchester, Royal Hampshire County Hospital.—Sen. Res. M.O. Also H.S. £200 and £150 respectively.
Wolverhampton Royal Hospital.—Res. Asst. S. and Surg. Reg. £300. Also Cas. O. and Res. Anæsthetist. At rate of £125.
The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Saxmundham (Suffolk), and at Totton (Hampshire).

Births, Marriages, and Deaths

BIRTHS.

BEARE.—On July 31st, at Deepdene Park-road, Dorking, the wife of C. E. Beare, M.B., F.R.C.S., of a daughter.
RICHARDS.—On July 28th, at Westbury, Wilts, the wife of Dr. W. K. A. Richards, of a son.
WILLIAMSON.—On July 29th, at Ziarat, Baluchistan, India, the wife of Major Williamson, O.B.E., I.M.S., of a son.

DEATHS.

CHAMPNEYS.—On July 30th, at Littlemead, Nutley, Sussex, Sir Francis Henry Champneys, Bt., M.D., F.R.C.P., aged 82.
HOWORTH.—On July 28th, Wilfred Howorth, M.R.C.S., L.R.C.P., Brevet Colonel, R.A.M.C.(T.), of Brunswick-road, Withington, Manchester, aged 63.
WALKER.—On July 27th, at a nursing home, suddenly, Capt. J. T. Ainslie Walker, R.A.M.C.(T.F.), F.R.S.M., F.I.C., F.C.S., &c.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

INDEX TO "THE LANCET," VOL. I., 1930.

THE Index and Title-page to Vol. I., 1930, which was completed with the issue of June 28th, is now ready. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 7, Adam-street, Adelphi, W.C.2. Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

NOTES, COMMENTS, AND ABSTRACTS

THE AUSTRALIAN CANCER ORGANISATION.

By Arthur Burrows, M.D., M.R.C.P., D.M.R.E.,
RADIUM AND CANCER ADVISOR TO THE COMMONWEALTH GOVERNMENT.

THE movement which led to the establishment of a modern cancer organisation in Australia had its origin in events about six or seven years after the end of the war. A group of public-spirited individuals formed a cancer treatment and research committee in Sydney, appealed for funds and raised £130,000 in Sydney and New South Wales. The successful treatment of an Australian patient by radium in America, under conditions which attracted some public attention, led also to representations being made to the Commonwealth government pointing out the necessity for the provision of satisfactory radium treatment in Australia. As a result of further inquiries this government decided to purchase 10 g. of radium, and a radium advisor was appointed to see that it was properly distributed and effectively used.

Shortly before the actual purchase of the radium the Minister for Health appointed a cancer advisory committee of prominent medical men and scientists to advise on any steps which should be taken in connexion with the new cancer movement in Australia. It was stated in the first instance that the government did not intend to supply all the money and material necessary for the establishment and equipment of cancer centres. At the same time the Minister encouraged local effort by grants to each research and treatment fund as it was raised. To New South Wales, Queensland, South Australia, and Western Australia, the Commonwealth government gave £5000, while in each instance the separate State governments gave to their own State funds a like contribution. So far Victoria and Tasmania, although they have contemplated action, have not fallen into line in this respect.

In Sydney the cancer research committee has been constituted a committee of the University, and a similar organisation has been created in South Australia. In Queensland a separate cancer trust has been formed which carries out its work as a completely independent body. In Western Australia the money was largely raised by Perth Hospital with outside help for a definite purpose, and when this object was achieved the fund was closed.

THE RADIUM CENTRES.

The national organisation which has been largely built up round the Commonwealth purchase of radium has been developed along well-defined lines. It was recognised in the beginning that for the public to receive the maximum benefit for radium treatment it must be administered only by those competent through experience and teaching to give it, and that for the further purpose of rendering the radium treatment offered more efficient, the radium should be located at large centres where considerable quantities of radium were available. It was, therefore, decided to establish one radium centre at each of the six capital cities. This rule has been fairly strictly applied, but in a country of the size and with the sparse population of Australia it has been found necessary to make a limited number of modifications.

Thus Townsville, in the North of Queensland, which fulfils the functions of the commercial capital of that district and is situated nearly 1000 miles from Brisbane, was given a small supply of radium. The large town of Newcastle was also brought into the scheme, while Launceston, which offers facilities practically equal to those of Hobart in Tasmania, was also constituted a sub-centre. Bendigo was the only other town thus favoured.

It is understood, however, that only a limited amoun of work, more or less clearly defined, ought to b done at these sub-centres, and that any case requirin treatment by large quantities of radium must be sen on to the main capital centres. If there is any doub cases are always advised to attend at a main centre and the requisite arrangements are made.

In each capital city the radium and cancer centre i established at the main teaching hospital, or in th event of there being no medical school, at the larges public hospital. In Sydney and Adelaide, wher each cancer research committee is a committee of th University, the University has been given charge o the radium. In Brisbane, Melbourne, Perth, Hobart and the minor centres, the radium has been placed i the custody of the local authority governing th hospital. The radium assigned to each hospital ha only been lent, and the loan has been made on term definitely set out in a signed agreement. This agree ment lays down the conditions under which the radium must be safeguarded, controlled for treatment, an made available for instructional purposes. It als sees, so far as an agreement can, that the investigatio treatment, and follow-up of cancer cases is carrie out in a proper and scientific manner.

The local authorities in addition to the radium hav provided, out of their local funds and subsidie deep X ray machines for cancer treatment, and th accommodation and staff laid down as necessary b the Commonwealth Department of Health. Notes cases are written on an official case-sheet which provided by the department and used throughou the continent.

In every centre the Commonwealth recommendatio has been carried out of establishing a treatment consulting committee consisting of a limited numb of surgeons, physicians, and specialists which meets regular intervals to consider, discuss, and institu the best means of treatment of the cancer cases referre to the centre, and, at the same time, a director ha been appointed for each centre in general contr of the radium and X ray work and acting as represen ing the committee in its absence. Usually the direct is a radiologist, but in one or two cases a surgeon physician has taken on the work and devoted himse almost entirely to it. This statement leads to anoth point—namely, that the Department of Health ha been insistent throughout that nobody shall hand radium unless he promises to give a certain defini minimum amount of time weekly to the work. Th correct use of radium demands a very considerab special knowledge on the part of the therapist ar as, in the majority of cases of serious cancer, th patient has only one reasonably good chance of succe from treatment, it is felt that it would be whol against the public interest to let patients take th risk of submitting to inefficient radium or X ra treatment. In the same way it is felt, that as mo cancer patients can travel, it is better for them to g to get satisfactory treatment at a big centre than th they should have inefficient treatment provided at their door.

In some States free railway passes are given to po patients travelling to the main centres, and it hoped that in due course the local authorities w be able to see that accommodation is provided f country patients who come to the metropolis whi they are waiting for radium treatment, or that th organisation is so worked out that the period waiting is negligible. It is usually found that th cost of keep and the loss of time and work is a great financial burden and domestic difficulty than th provision of the railway fare.

DIAGNOSIS AND RESEARCH.

The question of the diagnosis of cancer apart fro its treatment has received much consideration. the great cities adequate facilities for the micr

opic examinations of tumours is provided, and these cilities are rendered as simple and inexpensive as ossible. In fact, in the majority of instances istological examinations can be obtained free of harge. In Perth part of the cancer fund that has een raised is being expended on the provision of a ell-equipped pathological laboratory for the examina-on of cancer patients. This laboratory will constitute part of a complete cancer block which is in the course erection.

Some considerable time before the recent cancer ovement began in Australia the Commonwealth epartment of Health had started and carried it the policy of providing and staffing pathological boratories in many of the smaller centres which were ot well equipped with facilities for pathological aminations. These laboratories have been very ccessful, and are available in all those districts in hich they are established for the early examination pathological material taken from suspected cancer ses.

Research on a considerable scale is being conducted irectly under the auspices of the cancer research mmittee of the University of Sydney, and although ny aspect of the subject may be considered by this ganisation, it is taking particular interest in the oblems which arise in the course of the study of e action of X rays and gamma rays on tissues, and e application of observations on the fundamental ructure of organic and inorganic matter to cancer search. Research is also carried on with the help the Commonwealth Government subsidies in elbourne and Adelaide. Dr. Thomas Cherry carried t his work on the relationship of tuberculosis and ncer under these conditions, while the influence of et and other factores in the promotion of certain ood diseases and tumours in mice has been vestigated at Adelaide University. This work is ing continued under the auspices of the cancer search committee. At the Commonwealth Serum boratories at Melbourne a particular line of cancer vestigation has also been undertaken and is in ogress.

Research is being encouraged where possible at ery cancer centre, and an endeavour is being made to nduct the radium, X ray, and other treatment with is end in view. The centre is always prepared to tempt other forms of treatment besides the usual es by means of surgery, radium, and X rays. Lead eatment has not been very successful in Australia, ile diathermy has largely developed into an cessory rather than a primary method of cancer eatment.

The Department of Health acts as a coördinating ctor between all the cancer centres that have been tablished, and through the Cancer Supplement of e official journal *Health* publishes articles of interest cancer matters and gives items of news in respect the action which is being taken by different local thorities. Various of the States have published sters and pamphlets giving information to the blic on cancer, and the department is also interested this type of work and other publicity methods.

TELECURIETHERAPY AND EMANATION.

An attempt has been made to give full facilities r radium work. In the first instance 4 g. of radium ere mounted in a temporary container for administer-g "mass treatment" at the Melbourne Hospital. is treatment was carried on for a number of months fore necessity compelled the breaking up of the dium source and its distribution. This action is much regretted, as it had been intended to carry the work on a much bigger scale, but it should stated that there was a certain amount of sappointment in the results obtained while it was use. Arrangements have now been made to provide dium at Melbourne and Sydney for use as a radium omb." Melbourne has 1 g. of radium available d in use for that purpose and Sydney slightly less. A departmental emanation centre has been ablished at the University of Melbourne. The emanation provided is available to recognised centres which fulfil the conditions imposed by the Department of Health. The idea of establishing the radon centre was partly that it might be useful to fill gaps in the cancer organisation and might be employed in the treatment of those rare cases in which the necessity of travelling to a main centre would be a genuine hardship. But it was regarded as of still greater importance because it would provide a malleable source of radiation available for any rapid change in technique or for investigation; besides which it was felt that certain techniques, such as the gold "implant" technique of the Memorial Hospital, New York, and the special technique of Muir, also of New York, for the use of emanation ought to be tested and developed. Already it has been possible to institute certain improved methods in the mounting of emanation for treatment. The radium emanation is now in daily use.

An emanation station is also now complete and producing radon at the University of Sydney under the charge of the university cancer research committee. Emanation depôts for the carrying on of specialised emanation treatment and research are also in process of development at each of the other State capitals of the mainland. In every case a trained physicist will be in charge of the emanation station, which is placed under the general control of the University.

(To be concluded.)

THE DUTCH PESSARY.

To the Editor of THE LANCET.

SIR,—With reference to Dr. Norman Haire's letter on p. 225 of your issue of July 26th, I would like to make some comments on our experience of the Dutch rubber cap at the North Kensington Birth Control Clinic. The purpose of this design of cap is to be a diaphragm across the vaginal passage. To achieve this object, the circular rim must lie closely in contact with the vaginal walls, without the patient being conscious of its presence. In theory there are two levels in the vagina where this can be attempted; one, as high up as the length of the cervix will allow, and the other low enough to ensure that the anterior section of the rim is in immediate contact with the posterior surface of the pubic symphysis. The slope of the bone then acts as a stop to the downward passage of the cap rim when intra-abdominal pressure is exerted. As long as the circumference of the cap is large enough to maintain contact with the vaginal walls at every point, it does not matter at what degree of obliquity the plane of the rim lies.

Dr. Haire does not state clearly what is his aim in choosing the best size of cap for each patient. I have found that the higher level, although theoretically sound, has two practical objections: first, the vagina tends to become smaller in diameter at higher levels than at the lowest level, therefore a cap which fits a higher and smaller diameter tends to slip down and out when the patient moves or defæcates; second, many patients have not long enough fingers to reach the rim in this position, and so there are difficulties in extraction.

My aim in choosing the best size of Dutch cap is to find the smallest circumference which will remain snugly in contact with the symphysis when the patient exerts strong intra-abdominal pressure. I have found that a size which only just fulfils this condition neither comes out nor gives any discomfort, nor is its presence noticed by the wearer.

Unlike Dr. Haire, I have found that no type of cap is reliable when used alone. Sperms are able to swim up the moist vaginal walls past the rim of any cap. Our records contain several cases of failure from this cause; the patients' supplies of chemical spermaticide run out, and they trust to the cap alone, and after long periods of safety they conceive. At our clinic I no longer advise douching. I use the

small (grs. 2) pellet of quinine and urea hydrochloride made by Parke, Davis and Co. It can be inserted either above or below any type of cap. If it is used above I find quick solution is effected if a small quantity of water is first poured into the cap, and the pellet put into the water. Our patients much appreciate the added simplicity of this method, and the freedom from the habit of douching, a procedure which presents serious practical difficulties to many of them. A douche is unnecessary, because it is desirable that the quinine solution shall remain in the vagina as long as possible.

I am, Sir, yours faithfully,
HELENA WRIGHT.

IN THE MATTER OF AGE-LIMIT.

To the Editor of THE LANCET.

SIR,—I would like to endorse Ex-Temporary Civil Servant's letter in your issue of July 26th. It seems odd that committees who individually would never think of employing youthful and inexperienced doctors, no matter how keen or well qualified, are so ready to impose an early age-limit in the making of public appointments. Evidently experience has no value in this connexion, yet the same committee members acting on the boards of voluntary hospitals would most certainly consider age and experience as weighty factors in choosing the permanent staff.

In the first case there may be thirty or forty candidates to choose from, but the job goes to one of the juniors; in the second, with a field of possibly half a dozen, the younger men have no chance! Superannuation schemes are not the only explanation, although they frequently act to the disadvantage of medical employees. Medicine and surgery are still practised as they should be in most voluntary hospitals, but the practice of public health entails a series of special work which only the younger men will undertake with a view to special employment.

It may be added (and may I be forgiven for mentioning such a thing) that a certain forgotten episode known as the Great War made some of us middle-aged assistants five years older, five years wiser, and five years poorer.

I am, Sir, yours faithfully,
AN ASSISTANT MEDICAL OFFICER.

HEALTH IN WEST AFRICAN SERVICE.

THE report on vital statistics among non-native officials in West Africa shows a slight increase in the death-rate, from 6·7 per 1000 in 1928—a record year—to 7·7 per 1000 in 1929. It is interesting that of these deaths, 33 in all, only eight were due to tropical diseases: six cases of blackwater fever, one of typhoid, and one of malaria associated with lobar pneumonia. The remainder were due either to accident or such causes as cardiovascular degeneration and broncho-pneumonia, or appendicitis and other surgical conditions. The invaliding rate has decreased from 11·7 per 1000 in 1928 to 10·1 in 1929, the lowest figure yet recorded.

The remarkable improvement in the condition of the country is indicated by comparing some of the figures for 1903 with those of 1929. The death-rate per 1000 in 1903 was 20·6, and the average length of service of those who died was one year and nine months; the corresponding figures for 1929 are 7·7 per 1000, and eight years. Invaliding in 1903 reached 65·1 per 1000, with an average length of service of two years; now the average length of service is eight years two months, and the invaliding rate has fallen to 10·1 per 1000, as noted above. Another comparison can be made on the average length of service on termination: two years and four months in 1903, now eight years and two months.

It may be noted that the rates per 1000 of deaths and invalidings are lowest at the age of 30 years, and that while the death-rate is higher at 25 than 35, the invaliding rate is considerably higher at 35 than at 25; the second fact is possibly responsible for the divergence in the death-rates.

In his Chadwick lecture on Health in West Afric (THE LANCET, 1930, i., 843) Prof. D. B. Blacklock dre attention to the extreme expense of sanitary measure expense which handicaps sanitarians in their attem to eradicate disease with limited financial resource It must also be remembered that, though the repo of vital statistics already mentioned indicates th improvement in health among a certain part of th white community, it is no index of the health of th native population; Dr. Blacklock referred to some the diseases prevalent among the West Africa natives, and described the difficulties of treatmer where the medical service is limited and ideas sanitation primitive.

OPHTHALMIC HOSPITAL IN JERUSALEM.

THE report of this hospital, founded by the Ord of St. John, shows that it continues to do good wo in spite of a falling off in the numbers attendi during the year 1929. This was due to the disturl ances which took place last August, when Jerusale was in a state of siege for a week. The work of th six ophthalmic clinics in different parts of Palesti was also hampered; nevertheless the total numb of patients examined in the hospital during the ye was over 15,000, in the clinics over 14,000. Of th operations performed, over one third were on accou of trichiasis. The hospital is the possessor of tv plaques of radium. During the year, eleven patien were treated with radium, seven of them being cas of spring catarrh. Of the new patients seen, many as 92 per cent. were trachomatous. Accordi to the report the spread of trachoma is fostered l epidemics of acute conjunctivitis which, of lat have been unusually severe in Palestine.

TREATMENT OF ANAL FISSURE.

R. Bensaude and co-workers[1] have lately record their experience of the treatment of anal fissure by t method described by A. B. Graham in America in 192 Graham injects 5 per cent. quinine-urea solution und the base of the fissure, and F. C. Yeomans, in his bo on "Proctology," reports that this has given 70 p cent. of successes. Bensaude calls attention to t severity of the "fissure crisis" and the inten sphincteric spasm, which may last for ½ to 7 or 8 hou Palliative treatment has little effect and dilatati under anæsthesia is often required. The meth described is an ambulatory one, and all that is necessa is to inject about 0·25 c.cm. of the solution sup ficially under the external half of the fissure. Pu chthyol is applied to the surface. The injection painful and must be done rapidly; a very fine need is required. The injection may have to be repeat at intervals of 2–3 days. In Bensaude's small ser of about 20 cases all the patients benefited by t treatment and 11 lost their anal symptoms; in slight pain persisted at defæcation. In at least 7 the cases the fissure was anatomically cured. T defect of Graham's method which has impress English surgeons is the pain it causes. W. B. Gabri says that good relaxation of the sphincter can obtained by injecting a preparation called A.B. which is prepared for him by Messrs. Allen a Hanburys and is a 3 per cent. solution of anæsthes with benzyl alcohol 5 per cent. and ether 10 per ce in sterilised olive oil. Perhaps a combination of th methods would give satisfactory results.

"PERPLEXED" writes:—I should be much oblig if some of your readers could suggest some che absorbent material for a patient of mine with artificial opening, following operation of diverticulit to absorb the fæces, as she has to use large quantit of wool.

ADDRESSES AND ORIGINAL ARTICLES

SYPHILIS OF THE HEART AND GREAT VESSELS.

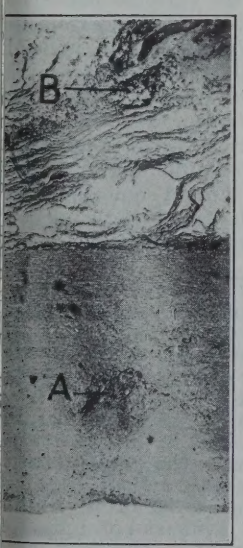
By Carey F. Coombs, M.D., F.R.C.P. Lond.,
PHYSICIAN, AND IN CHARGE OF THE UNIVERSITY CENTRE OF CARDIAC RESEARCH, GENERAL HOSPITAL, BRISTOL.

LECTURE III.*

Changes in the Aorta.

The most constant and at the same time the most striking lesions seen histologically are those in the wall of the aorta. These are not always easily discriminated by the naked eye from those of atheroma with which in fact they are often mingled; yet histologically the two lesions are as different as possible. The syphilitic lesion is inflammatory while the other is degenerative; the one invades the media from the adventitia along the track of the vasa vasorum, while the other, beginning and centring in the intima, encroaches upon the adjacent part of the media. In one respect, indeed, they are alike, in that each is capable of breaking up the elastic fibres of the aortic wall, but even here there is a difference, for syphilis breaks into those fibres oftener and far more seriously than does atheroma. Syphilitic aortitis is a chronic inflammation (Fig. 5), marked histologically by mononuclear response (Fig. 6) which is seen scattered about in the peri-aortic connective tissue, and banked up in the adventitia, against the outer aspect of the media. Here the cells—lymphocytes, plasma cells, and some fibroblasts—collect round the vasa vasorum, and around them enter the media from without inwards. In the media spaces form between the fibres, which tend to spread along and around the vessel. These become filled partly with the inflammatory cells, partly with new blood-vessels, partly with new fibrous tissue. As these new elements spread they tend to become connected with one another and thus to break off the elastic fibres by which they are bounded. By this process of coalescence large spaces (Fig. 7) and long fissures are formed, gravely lowering the value of the aortic wall as an elastic and resilient structure. It is easy enough to see from the picture of any syphilitic aorta how aneurysms, both saccular and dissecting, are formed. Indeed it is wonderful that any syphilitic aorta fails to become aneurysmal. One change that tends to prevent this is the fibrous thickening of the intima that is formed, like a kind of dam, opposite the weaker places in the media (Fig. 8). This is so obvious that it is impossible not to regard the two phenomena, medial thinning and intimal thickening, as cause and effect. This thickened intima may subsequently undergo fatty change and calcareous infiltration, thus producing a kind of atheroma; yet a kind quite different from that seen in senile or decrescent arterial change which begins in the intima and leaves the adventitia untouched.

Fig. 5.



Low-power view of section through wall of syphilitic aorta.

Fig. 6.

Higher magnification of area marked A in Fig. 5, to show mononuclear infiltration with vascularisation in the media.

Some accounts of these lesions ascribe great importance to changes in the walls of the vasa vasorum, labelled endarteritis. I believe, however, that it is a fallacy to suppose that the characteristic change in the vasa vasorum is intimal. The reverse is true, for there is an intense cellular reaction around these vessels which follows them on their course into the media, a fact which shows quite clearly by what channels the virus of syphilis breaks through the aortic defences. Any change that can be marked in the walls of these small nutrient vessels surely arises from the outside. At all events, that change is as much medial as intimal and, though it may amount to complete occlusion of some vessels, could scarcely be held responsible for so gross an injury to a first-class tissue as is to be seen in the media of the syphilitic aorta.

Considered longitudinally, this process often fades into normal aorta within a short distance from the root of the vessel, which it usually encircles. It is on the sigmoid and suprasigmoid portions that the chief stress falls. At the cardiac end of the tube the process ends abruptly, not passing down into the ventricular walls as a rule. I found no example of spread in this direction. The wave spends itself and is checked. Yet in ending here the inflammatory process involves two structures of vital importance: the mouths of the coronary arteries and the aortic semilunar valves. This stenosis of the coronary mouths is a most striking pathological change, as striking both by reason of its individuality and of its consequences as, say, mitral stenosis. What is so remarkable is to see the inflammatory reaction leave off abruptly as the aorta passes over into coronary artery. The walls of the coronary arteries themselves are scarcely ever touched by this invasion. Nevertheless it comes right down the aortic wall to the very angle of the coronary opening (Fig. 9), and at this point the adventitia is intensely inflamed. It is easy to see how this leads to a fibrosis round the orifices of the coronary vessels

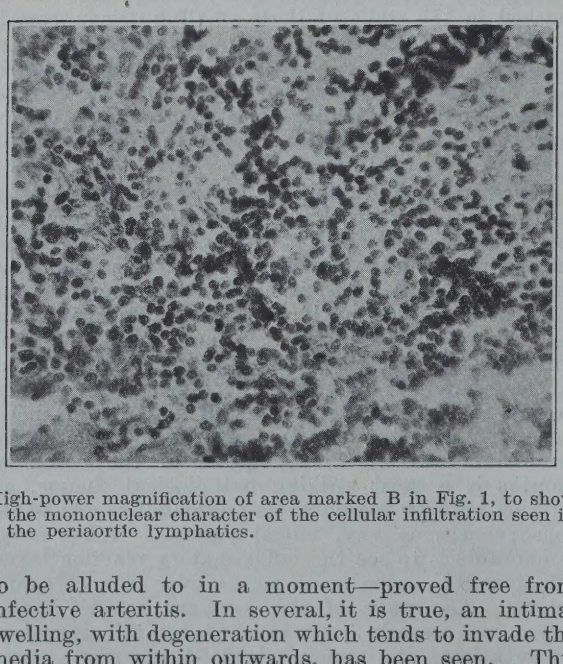
* The third Lumleian lecture. The previous two lectures appeared in THE LANCET of August 2nd and 9th respectively.

by which these are nipped in an ever-tightening strangle-hold.

Scarcely less remarkable is the effect of this ring of inflammatory change on the aortic semilunar cusps. If the commissures between neighbouring cusps be examined, they are often seen to be swollen, and the swelling has spread into the adjacent portions of the cusps themselves. These are thereby stiffened and shortened, and thus tethered at their aortic attachments in such a way as to render them inadequate. With the microscope this swelling is seen to be partly inflammatory (Fig. 10), partly œdematous. Scott and Saphir[46] find that œdema precedes cellular infiltration. Whether this is so or not, both changes are seen, sometimes one, sometimes the other being predominant. The endothelium tends to proliferate and to be shed at this, the commissural, end of the valve cusps, which may thus become adherent to each other or to the aortic wall. From the frequency with which the cusps perforate at this part of their extent—the "reticulation" described and figured by Corrigan—it seems that this process involves them in a kind of dystrophy; or perhaps these accidents are wholly due to the tethering effect of the infiltration at the commissural margin of the cusp. Immediately beneath the swollen and inflamed commissure, which is a kind of cushion of subintimal connective tissue, the media usually exhibits the characteristic syphilitic reaction (Fig. 11).

So far, then, this is the picture: an inflammation reaching the aorta from without, invading and breaking up its middle coat, and spreading heartwards until it stops at the level of the sigmoid portion, where it strangles the coronary arteries and ties down the aortic semilunar cusps. This stricture of the coronary mouths (Figs. 12, 13) is all the more striking because the coronary arteries beyond are free from disease. That this is so is proved by section of the coronary trunks and branches, which have in all cases but one—

FIG. 7.



High-power magnification of area marked B in Fig. 1, to show the mononuclear character of the cellular infiltration seen in the periaortic lymphatics.

to be alluded to in a moment—proved free from infective arteritis. In several, it is true, an intimal swelling, with degeneration which tends to invade the media from within outwards, has been seen. This appears to me to be identical with the atheromatous change from which the coronary arteries of persons over 50 are seldom quite free. I do not think there can be any doubt that the coronary arteries themselves are very rarely attacked by syphilis, and this view is strikingly supported by some observations which Dr. Bruce Perry kindly undertook on my behalf. He injected into the coronary arteries of five hearts showing signs of syphilitic infection an opaque

FIG. 8.

substance, after the method used by Gross, Campbell and others; and by X raying these specimens was able to demonstrate the freedom of the coronary arteries and their branches from any stricture (Fig. 14). This freedom from interruption in the course of the vessels forms a striking contrast with the extreme stenosis of its mouth. An artery of which the openings from the aorta are so narrowed as to be almost invisible nevertheless opens up immediately afterwards into a tube with smooth walls and normal calibre. In senile or "decrescent" hearts, on the other hand, the bore of the coronary arteries varies greatly and exhibits may strictures. The pulmonary artery, examined by me in nine cases, showed some departure from the normal in four, the changes being similar to those in the aorta but much less pronounced.

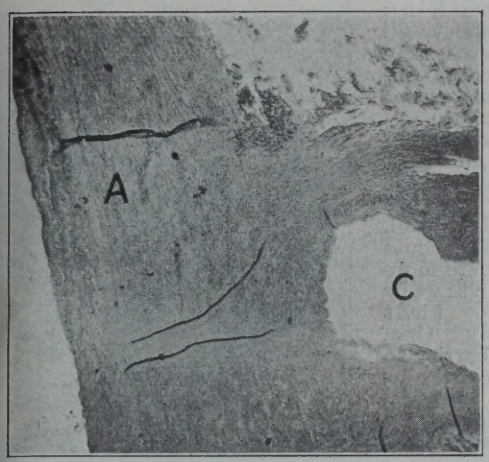
LESIONS IN THE MUSCULAR WALL OF THE HEART.

The muscle cells.—In most of the hearts examined some evidence of malnutrition of the myocardial cells was found. Usually this was mild in degree and scattered in distribution. For example, the auricular walls in three instances showed the same kind of fatty change that is seen in them in advanced cardiac rheumatism—similar in kind but by no means so severe in degree. In six cases the walls of the ventricles, in which it is usually more difficult to detect these degenerative phenomena than it is in the auricular walls, showed clear evidence of impaired nutrition in the form of fatty change, and even more definitely in a shrinkage of the total volume of the cells. In two hearts the fibres of the auriculo-ventricular bundle showed the same kind of change but I did not see it in any sinu-auricular node. Once only did I find a gross focal lesion of the muscular tissue: a wedge of necrotic muscle, free from inflammatory reaction, in the upper part of the interventricular septum (Fig. 15). Near this there were some lesions of arterioles.

The *connective tissue planes* of the cardiac wall undergo three kinds of alteration. The one most often seen is an increase of fibrous tissue that takes place with little or no inflammatory reaction. In the areas where this is seen the muscle-fibres are reduced in number and size, and it is therefore a "replacement

rosis. In some degree it is present in most philitic hearts. The largest areas that I have en were in a papillary muscle of the left ventricle, d in Dr. Herapath's case, already mentioned, here scar tissue and fat cells had almost entirely

FIG. 9.



w-power view of section of aorta at origin of a coronary artery, showing adventitial and medial lesions of aorta. Note hat these lesions, while sparing the coronary wall, are so situated as to constrict the coronary opening. A = aortic wall.) = lumen of coronary artery.

placed the muscle-fibres of the auriculo-ventricular ndle. I examined the bundle in twelve cases but nd no gross connective increase in any of them, r in the sinu-auricular node, examined thirteen nes. The absence of frank inflammatory change s a great surprise to me. Only in one heart did I a granulomatous focus. This was very small l well out of the way in the subpericardial fat. several thousand sections of cardiac muscle did not once see a granuloma. When an erative endocarditis was added to the syphilitic ion, embolic foci were noted in the cardiac wall. is is the rule in warty endocarditis. The third d of change is an interesting one. It has been cribed before and regarded as an inflammatory ction to infection. The appearances are those of weak cellular response—a few plasma cells and phocytes—drowned in serum, which gives the ues a dropsical appearance (Fig. 15). It is icult to think that the same infection which can ite so brisk a reply in the aortic wall should be able rovoke in the cardiac wall nothing better than this tery response. In over 100 hearts damaged by er infections nothing quite like it was seen.

We have been told by some observers that this is an ammatory reaction excited by spirochætes lying nt in the cardiac wall, and as this is a point on which ne but the most experienced observer can offer an nion, I called on Prof. Levaditi last autumn at the steur Institute. He was kind enough to undertake examination of portions of two hearts in which we l already found aortitis and myocardial fibrosis on enerous scale. He reports as follows:—

"We have examined the blocks that you sent by the er impregnation method, that up till now has given the most reliable results. We have found it im- sible to demonstrate spirochætes, in spite of the ence of aortitis. We shall continue to search, and report if we find anything positive."

oming from so experienced an authority this dict has peculiar weight; it is at all events clear that pirochætes are in the myocardium they are so few o be very difficult to find.

nother surprise has been the freedom of the nary twigs from inflammatory change. One s, of course, medial hypertrophy in hearts that are themselves hypertrophied, and atheromatous change in subjects of the appropriate age. But only one heart has shown signs of an actual arteritis in these twigs, and in this instance both media and intima were involved, the limiting elastic lamina being disintegrated (Fig. 16). It was near to these arteriolar changes that the wedge of necrotic muscle was noted of which I spoke just now. My interpretation was that arterial disease in this area had ended in the formation of an infarct.

Blood-vessels.—I must here record what was to me the most significant and revealing of all the phenomena noticed in the cardiac wall. As I was making notes on changes seen in sections of the interventricular septum, something which I had never seen before in the cardiac wall struck me, and I wrote down "large venous sinuses immediately under the endocardium." These were obviously associated with muscular atrophy and fibrous increase (Fig. 17), as they ran through the centre of atrophic areas. On reflection it was borne in upon me that these were the dilated Thebesian veins that Wearn[63] has described and, as in his cases, they were associated with stenosis of the coronary openings. In hearts injected by Dr. Perry the injection mass did not seem to have penetrated these sinuses.

Rheumatism and Syphilis Contrasted.

We are now in a position to reply to the four questions that prompted this histological inquiry. These are arranged so that one reply may in some measure clear the ground for the next.

(1) The aortic valves are rendered liable to the implantation of secondary infections by a process that is radically different from that of the rheumatic infection. In rheumatism the infective agent enters the depths of the valve from the coronary stream, excites a reaction there which, so to speak, bursts the valve, or at all events floats off its endothelium, leaving a roughened and injured surface. In syphilis the process also begins in the depths of the valve, and causes it to swell, until here also the endothelium is injured and desquamates. The raw surface may become adherent to its neighbouring valve or to the aortic wall, or it may invite and receive a deposit of clot, with micro-organisms laying therein the foundations of an endocarditic vegetation. But the syphilitic injury is inflicted, not through the medium of the coronary blood-supply, but by lymph-borne virus

FIG. 10.

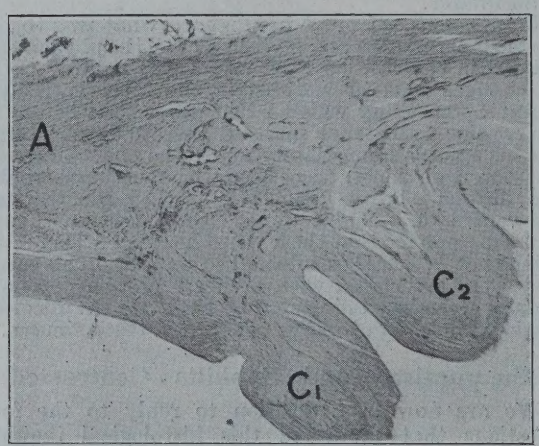
which filters from the adventitia through the media till it is arrested at the valvular attachments and especially at the commissures (perhaps because it reaches these first). Here it causes an inflammation which interferes with the flow of lymph through the valvular tissue, rendering it both œdematous and fragile. As this process is limited to the commissures and adjacent parts of the cusps, it is interesting to note that here also—in the only early specimen I have seen—the

infection that provoked an ulcerative endocarditis seems to have been implanted.

(2) Lesions of the sinu-auricular node and the auriculo-ventricular bundle were not found. Such changes as have been seen in the cardiac wall are almost exclusively dystrophic; these are found in

FIG. 11.

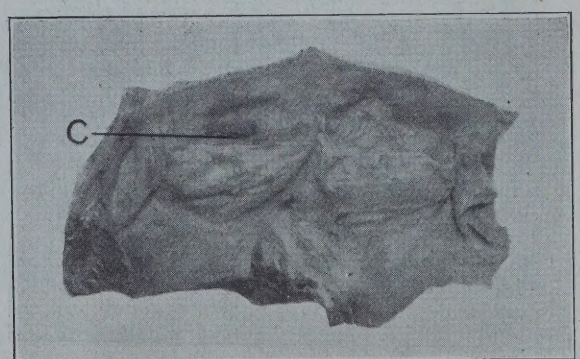


Another commissure showing vascularisation of the media concentrated at this point. A = aortic wall. C_1, C_2 = cusps of aortic valves, cut off short.

all cases, whereas definitely inflammatory foci were almost non-existent. Whatever else may be laid to the charge of the syphilitic spirochæte, it cannot be accused of remaining alive in the cardiac wall in such numbers as to provoke an obvious inflammatory response.

(3) The absence of cardiac infarction is easily explained. There is no disease in the coronary arteries and therefore no occasion for clotting within their lumen. This absence of gross coronary disease is a very striking fact, since it goes a long way to prove that the cardiac failure of late syphilis is not due to the transmission of the infection into the myocardium along coronary avenues. The frequency with which cardiac pain is experienced in cardiac syphilis is

FIG. 12.



A coronary opening C much narrowed by aortic syphilis.

probably related to the obstruction of the coronary orifices. Perhaps it is also in part due to the periaortic inflammation, which may surround the nerve trunks, though without, as far as my observation goes, invading them; and it may be that this element is responsible for the fact that pain in cardiac syphilis may often occur apart from exertion or other obvious provocative. This periaortitis is a striking phenomenon, and one cannot be surprised at the impression that it made on the mind of Clifford Allbutt, who w so familiar with it. Yet cardiac pain occurs when the is no periaortitis, as in atheroma and hyperpies and even when there is no gross change in the arter tree, as in a few cases of pernicious anæmia. I can see nothing common to all these widely diverse conditions except a failure in the supply of oxygenated blood to the cells of the cardiac wall. Nothing could interfere more effectively with that supply than the barrier to coronary inflow which aortic syphilis imposes. The Harvey film of this College showed the beating heart paling in systole and flushing in diastole, flushing because its coronary arteries are filling w blood, as Anrep has taught, and passing that blood to the rich capillary system with which the muscu wall of the heart is endowed. But if the coron openings are so narrowed that blood cannot be dra through by the ventricular relaxation, what is happen? To this question two sets of facts re eloquently; one of them, the liability of the syphili heart to sudden suspension of work; the other, state of the cardiac wall as revealed by the microsco The cardiac wall demands blood in diastole but is appointed by the coronary stricture, and has to pu

with such meagre supplement as it can get from Thebesian veins. Small wonder that the mu fibres shrink and are replaced by fibrous tissue. dangerous a matter as this starvation of one of vital tissues must make itself known some whenever the demands of exercise threaten to g far; and that protest takes the form of stenocard plain hint that cannot be ignored.

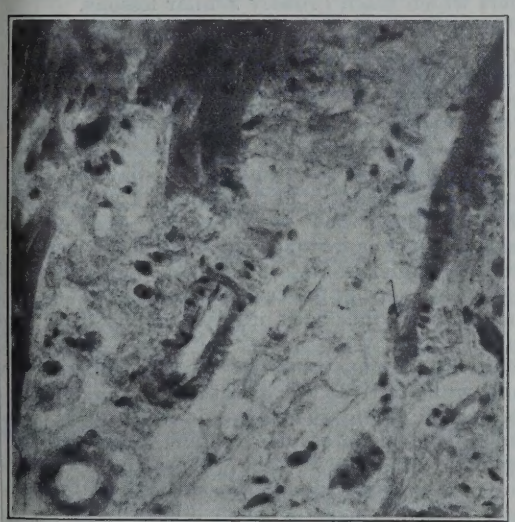
(4) The last of our questions, that which asks

ese lesions take so long to develop, cannot be swered with full assurance. Yet I believe the idence furnished by a consideration of the histo- gical facts justifies certain significant deductions. o one approaching these facts without bias can fail be struck by the fact that the most constant and rious lesion is an inflammation of a productive nd in the tissue immediately surrounding the aorta. ow Klotz,[33] in 1918, wrote an important paper which s been somewhat neglected, though not by Clifford lbutt, who recognised its value when speaking on sceral syphilis in 1921. The burden of this paper as the significance of the lymphatic arrangements the aortic sheath, especially as these concern the stribution of the syphilitic virus.

THE LYMPHATICS AROUND THE AORTA.

This view accords with the histological facts. he inflammatory reaction is at its most intense in e connective tissue that surrounds the aorta. orbidden by the outer wall of the media to pass on a direct line, it filters through by following the asa vasorum. These are thereby soaked in poison nd their walls swell. The virus, passing in along ese small vessels, separates the layers of elastic

FIG. 15.

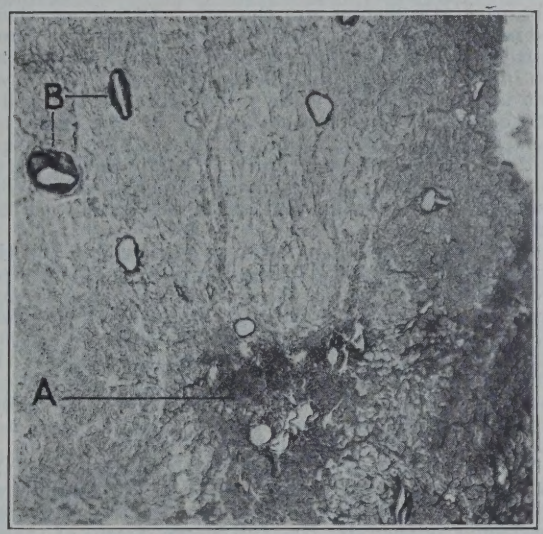


A of "œdema" in myocardium, showing a few plasma cells.

ti ue from each other, makes between them spaces fi d with inflammatory cells, organised blood-vessels, a new connective tissue, and often breaks through t elastic fibres so freely as to create wide fissures e ending through the whole thickness of the media. T intima saves the situation by buttressing the w kened media, which nevertheless may so crack a yield as to allow aneurysms to form. In any c the loss of elasticity in the aortic wall is a heavy b w to circulatory efficiency. Other blows, even n e serious, are sustained because the infective p cess spreads both within the media, along the in rfibrous planes, and without, in the periaortic ly phatics, to the aortic base, where it nips the co nary arteries and deforms the valves. The first of hese starves the ventricular wall; the second, b making the aortic valves leak, increases its work. If ome malign agency, endowed with a capacity for pu oseful activity, were to busy itself with plans fo bringing the action of the heart to an end, it co d scarcely hit upon a subtler plan than this.

he point is that these infective phenomena arise so ewhere outside the aortic wall and reach it by ly phatic channels. Whence do they come? We de ve a hint of the importance of this matter from a re nt paper by R. O. Stern[47] which Dr. Macdonald Cr hley commended to me, a paper which argues, on histological grounds, in favour of a lymphogenous origin for tabes dorsalis and suggests that it is from the aortic lesions that the toxins are derived. This is not quite the whole truth, I think, for the incuba-

FIG. 16.

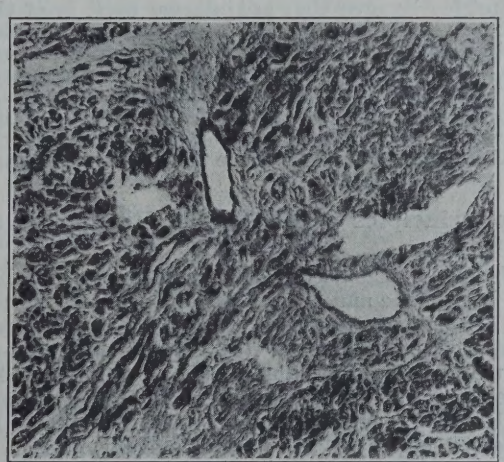


Section of myocardium showing (A) wedge of necrotic muscle, (B) arteritis of coronary twigs.

tion period of the tabetic lesion is not so long as that of the aortic. Is it not probable that there is some common reservoir of poison from which both spinal and aortic lesions are initiated?

I know that we are told that spirochætes and an inflammatory reaction are found in the aortic and myocardial tissues within a few months after infection. But the same is true, presumably, of every tissue and organ in the body. It has just been satu-

FIG. 17.



Wall of left ventricle to show dilated Thebesian veins coinciding with muscular atrophy and increase of connective tissue.

rated with spirochætes, and it would be remarkable if these inflicted no immediate injury. We know, also, that in all parts of the body remnants of this infection linger, setting up a granulomatous reaction here and there, and also inflicting permanent injuries on a few arteries. No tissue is exempt from this kind of accident; yet in the 18 hearts that were examined thoroughly, only one showed a granulomatous focus and that a small one; while only

one other displayed any inflammatory lesion of the coronary branches. On the other hand, aortitis was present in all of them. It is this, the lymph-borne lesion, that is the inevitable one; the blood-borne phenomena are comparatively rare accidents. Here again is a likeness to the nervous lesions of syphilis. Arteritis, gumma, and myelitis are the exceptions; tabo-paralytic lesions are the rule. Of course, there are in both systems examples of overlapping. Gummatous lesions may occur in patients who also display the later lymphogenous phenomena. But the broad fact is that syphilis, after it has entered the body, whether by a local inoculation or by the maternal blood, attacks both systems in three different stages and in three different ways; bacteriæmic, focal, and lymphogenous phases may be successively recognised in the heart as well as in the cerebro-spinal axis.

One other parallelism between the cardiac and the nervous lesions is that, being lymph-borne, the virus provokes a reaction in the fibrous investments that would be unimportant if it were not that vital tissues are included within those investments. Possibly, the truth is rather this, that in this last phase of the infection the lesions are more widely distributed than we suspect, but that we know nothing about them except where they attack vital organs and excite noticeable symptoms.

When we consider all these analogies between the spinal and the aortic manifestation of late syphilis we are not surprised at the occurrence of the Babinski syndrome, either in its full-blown form of tabes with aneurysm or in the less distinct developments of a similar coincidence. And we begin to ask whether it may not be more than a coincidence; whether these may be two nearly related branches of a main stream. If so, from what reservoir does that stream issue? May this not lie in the mediastinal lymph glands? Klotz hints at this, speaking of the mediastinitis that accompanies aneurysm. This is not always perceptible to the naked eye, yet it may at times lead to dense mediastinal fibrosis. I have a vivid recollection of the difficulty that it added to the removal from the thorax of a certain large aneurysm that I wanted for a museum specimen. Lymphadenitis is a prominent feature of secondary syphilis, and presumably this is as true of the glands that we cannot feel because they are internal as it is of those that we can feel because they lie externally. It is likely, so it seems to me, that within these glands the infection is apt to survive, and thence to pour out a stream of toxins which, carried by lymphatic channels, do irreparable injury to both aorta and cord. It is an interesting hypothesis, the verification or rejection of which must be left to those who have the material and the skill to use it.

The Principles of Diagnosis, Prognosis, and Treatment.

Usually a diagnosis of organic disease of the heart has been made and a cause has to be found. In cases of (1) aortic regurgitation, (2) general or aneurysmal dilatation of the aorta, (3) cardiac pain, (4) ventricular, or less often auricular, or junctional failure, especially when they occur in a middle-aged male, evidence of a syphilitic origin must be sought. It is obtained either in the patient's history, or in the presence of some other syphilitic lesion such as tabes or a periosteal node; or by a Wassermann test. Ulcerative endocarditis may have a syphilitic basis, and similar evidence should be sought if the valvular lesion be aortic. The discovery of a syphilitic element in such a case may favourably influence the reaction to treatment. Sometimes it is justifiable, even when all these modes of inquiry end in nothing positive, to treat the patient as if he had been proved to be syphilitic; and occasionally the results justify that suspicion.

There is a group of patients who, convicted of some other form of syphilis, also display doubtf signs of cardiovascular disease. Of these, Phillips[42] sa in 1897 that "evidences which we might sometim set aside as too slight to denote important cardi disease must not be so set aside in syphilitic persons

Prognosis, in the nature of things, cannot be goo once a definite diagnosis of cardio-aortic syphilis h been made. My own 103 cases have yielded a numb of data that I may summarise thus:—

TABLE VII.

Years since first seen.	Alive.	Dead.	Total.
1– 4	21	19	40
5– 8	7	13	20
9–12	1	27	28
Total	.. ..	.. ..	88

In 17 fatal cases death followed onset of symptoms in 2·5 yea

These experiences may be compared with those Mitchell Bruce, who gives 5¼ years from the onset symptoms as the average duration; of Deneke, w found 84 per cent. fatal in four years; and w others which teach broadly similar lessons.

The precarious outlook before the cardiosyphil is proverbial. In this respect the syphilitic surpas all other cardiac lesions. This is because no ot cardiac lesion so effectively reduces the blood-sup of the heart to an irreducible minimum without margin for emergencies. Evidence of coron stenosis or of the resulting myocardial starvatio therefore particularly unwelcome. I am, of cou not forgetting that we have in the occasio coexistence of aneurysm an additional reason dreading sudden catastrophes; and it is not poss to give a reassuring forecast to the relatives or frie of anyone who has been proved to suffer from car syphilis.

Notwithstanding these depressing facts, it is worth while to treat this disease thoroughly. The therapeutic axiom that I would venture to stat that a diagnosis of cardiac syphilis carries with it implication that its subject will be under treatm more or less active, for the rest of his life. It se clear, from the look of some of the lesions I h examined, that even when the syphilitic pro itself is terminated the residual damage, to the a in particular, so reduces the efficiency of the ci latory pump that the addition of other deleter processes, especially those of atheroma and arterial tension, brings to the ground a man wh he had had no syphilis might have lived ten or tw years longer. Therefore no matter how succes the antisyphilitic treatment may appear to be, ought not to forget that the more completely infection is controlled the less residual injury t will be, and the better will the patient be able to the other stresses and perils in which advan years must inevitably involve his arterial tree.

The broad plan of treatment indicated is a tinuous supply of potassium iodide and merc continuous that is, in the sense that the patient not stop it unless the doctor tells him to; superimposed on this background of contin treatment, an occasional course of organic ars For instance, one should try to persuade the pa to receive about twice in a year a course of novars benzol given in moderate weekly doses, not rising above 0·45 g. per dose, and amounting total of 5 g. in all. It is much better to sp the course out over a long period than to attem hurry through it, the difficulty being that the pa

turally wants to get the maximum amount of nefit in the minimum amount of time. Often in the ly stages he feels so well that he cannot see why much fuss is made over him, and this makes him the less inclined to be patient and persevering. My n belief, however, is that continuity in the adminis- tion of iodide and mercury is of more importance an courses of organic arsenic. A diagnosis of tic syphilis also implies unfitness for strenuous rk and for violent exercise of any kind. More- r, it imposes on its subject a need for strict temper- e in the use of alcohol.

f the sole reason for an interest in the subject that have been discussing lay in the opportunity that ffers for successful treatment then, indeed, our time uld have been largely wasted. There is, however, far stronger motive impelling us to study this ease and to make known the outcome of our dies, and that is a desire to emphasise the urgent d for prevention and early treatment of syphilitic ection. If it is a melancholy reflection that in this ease we see a wholly needless wastage of valuable s we may perhaps derive consolation from seeing t also a supreme example of the immense power of ghtened public opinion as an engine of preventive licine.

THE BI-COLOURED GUAIAC TEST FOR THE CEREBRO-SPINAL FLUID.

BY J. GODWIN GREENFIELD, M.D. EDIN., F.R.C.P. LOND.,

PATHOLOGIST TO THE NATIONAL HOSPITAL, QUEEN-SQUARE;

AND

RUBY O. STERN, M.B. LOND.,

CLINICAL ASSISTANT AT THE HOSPITAL.

THE bi-coloured guaiac test on the cerebro-spinal fluid was introduced in 1929 by de Thurzo, who, working in the laboratory of the National Hospital for Diseases of the Nervous System, applied this new colloidal reaction to the cerebro-spinal fluid and investigated its behaviour with a number of pathological fluids.

The object of this paper is to record the results we have obtained in a further series of fluids examined in the same laboratory, and to assess the practical value of the test.

Description of the Test.

The colloidal system used in the bi-coloured guaiac (B.G.) reaction is a suspension of guaiac resin with two coloured solutions of dyes, naphthol green and brilliant fuchsin. The brilliant fuchsin tends to be precipitated along with the resin in certain pathological fluids, and thus we obtain colour changes from red to green through an intermediate, but obvious grey coloration. The B.G. solution itself is easy to prepare and gives remarkably constant reactions. Standardisation of the solution is therefore unnecessary.

Theoretical considerations of the reaction will not be discussed here, for de Thurzo has dealt with them in his paper.[1] It is sufficient to state that he ascribes the reaction to a particular sensitiveness of the colloidal system used to one fraction of the protein content of the cerebro-spinal fluid, euglobulin. A relative increase in this fraction, as found in different forms of neurosyphilis, causes precipitation of two components of the colloidal system and a characteristic change in colour. The Lange colloidal gold reaction appears to be produced in the same way. We have performed this reaction also on all the fluids in our series for the purpose of comparing the two reactions.

PREPARATION OF THE SUSPENSION.

Two solutions are required: *Solution 1* consists of 0·2 per cent. sodium chloride with 1 c.cm. of ½ per cent

sodium carbonate added to each 100 c.cm. of saline. The sodium carbonate solution keeps indefinitely. De Thurzo suggests that the saline should be prepared freshly for each test from a stock 10 per cent. solution diluted, but we have found it advisable to make up the 0·2 per cent. solution from the dry salt each time. *Solution 2* is the bi-coloured guaiac suspension, which is prepared as follows: 0·22 c.cm. of 20 per cent. tincture of guaiac (B.P.C.) in 9 c.cm. of absolute alcohol are added to a flask containing 40 c.cm. of distilled water.

This mixing of the suspension must be done very slowly and with constant shaking of the flask. The best method of mixing these two solutions is to pipette the guaiac tincture into the water from a 1 c.cm. pipette, allowing not more than 0·5 c.cm. to be delivered at a time, and shaking well between the delivery of each few drops. As the success of the test depends on the thorough mixing of these two solutions, it is important not to hurry this step. 2 c.cm. of a watery solution of naphthol green (Gurr) are then slowly added to the suspension. The flask should be shaken after this is added. Finally, 0·3 c.cm. of an alcoholic solution of brilliant fuchsin (basic fuchsin, Gurr), is added, and the flask again shaken. *It is then left to stand for 30 minutes before use.*

A good suspension should be slightly opalescent and of a dark cherry red colour when freshly prepared. The colour fades to a light cherry red by the end of half an hour, and after twelve hours the colour is a rather dirty shade of pink. The suspension can only be used within three hours of preparation, as after this time the sensitivity alters, and anomalous results are obtained.

TECHNIQUE OF THE TEST.

Each test is carried out thus: ten test-tubes, 4 inches in length, are set out in a rack. 0·5 c.cm. of cerebro-spinal fluid is put into the first and second tubes, leaving the pipette in the second tube. 0·5 c.cm. of solution 1 is added to each of the tubes 2 to 10. The cerebro-spinal fluid in tube 2 is mixed with the saline, and 0·5 c.cm. is transferred to tube 3. Mixing takes place as in tube 2, and 0·5 c.cm. is transferred to tube 4, and so on to tube 10, from which 0·5 c.cm. is removed and rejected. The dilutions of cerebro-spinal fluid are therefore 1/1, ½, ¼ .... to 1/512. 0·5 c.cm. of the B.G. suspension is added to each tube. The rack is well shaken and set aside. The results are read after 12 to 18 hours by transmitted light, preferably by electric light.

In reading the test the alterations in colour are represented by numbers: 0 = No change. 1 = Slight precipitation, some turbidity; no change in colour. 2 = Red precipitation; upper fluid greyish or greyish-red. 3 = Red precipitation; upper fluid greyish-green to dull green. 4 = Red precipitation; upper fluid vivid green. There is no difficulty about reading the changes in colour indicated by figures 3 and 4. The only difficulty arises occasionally in deciding whether the change in colour is represented better by the figures 1 or 2. This difficulty soon vanishes with experience in reading the test.

Results.

Our series comprised fluids from patients with the following diseases (the figure after the disease indicates the number of cases of the particular disease in which we examined the fluid): general paralysis (52), tabes dorsalis (23), cerebro-spinal syphilis (11), disseminated sclerosis (21), cerebral tumour (7), spinal compression (6), cerebral abscess (2), syphilitic meningitis (2), chronic meningitis (2), polyneuritis (2), hemiplegia, cerebral thrombosis, acute meningitis, Friedreich's ataxia, osteitis of orbit, local meningitis, cerebral malaria, third nerve palsy and arthritis, one case of each. The fluids of many of the syphilitic cases, especially those of general paralysis, were examined on several occasions. The Lange reaction was done first on every fluid, and only those which gave a reading of (2) in at least one tube were used for the B.G. reaction. It was found that fluids giving a reading of only (1) in the Lange reaction did not give any colour change with the B.G. reaction, and except for control cases they have been excluded from this series.

The results indicate that the B.G. reaction clos resembles the Lange reaction in its behavio towards syphilitic fluids. The only fluids wh produced complete precipitation in any tube w a clear green supernatant fluid in the B.G. reacti were, with a very few exceptions, those from cases general paralysis. The exceptions were: a case polyneuritis with a protein content of 1 per cen two cases of tabes dorsalis, and three cases of disse inated sclerosis. Reference to these cases will made later. We found that, with the exception ag of certain cases of disseminated sclerosis and cases with an exceptionally high protein conte precipitation represented by figures 2, 3, and occurred only in neurosyphilis. The increase protein content necessary to produce a very sli precipitation of the B.G. suspension produced very definite "shift to the right," or mening curve, in the Lange colloidal gold suspension. example, a fluid from a case of polyneuritis wit protein content of 0·45 per cent. gave a La reaction of 0001123333, but a completely negat B.G. reaction.

Whatever the theoretical basis of the react may be—i.e., whether the colour change is due an increase in the proportion of euglobulin or no it is clear that the B.G. reaction is decidedly m sensitive to syphilitic fluids, however low th protein content, than to non-syphilitic fluids wit very high protein content. The B.G. suspens thus seems to be more selective in its reaction tha the Lange gold-sol.

GENERAL PARALYSIS.

The majority of fluids from cases of gen paralysis gave a reading of the type 244444 It was rare to find complete precipitation in the tube—i.e., with undiluted cerebro-spinal fluid. strongest reaction was seen in the third tube practically every case. Not uncommonly a sl reaction in the first tube was followed by comp precipitation in the next six, a reaction of the t 1444444211. In only eight out of our 52 fl from cases of general paralysis was there less t complete precipitation in at least one tube—a about 14·5 per cent. failed to give the paretic react Of these eight fluids, only three which were exam on several occasions, gave at any time comp precipitation with the Lange reaction.

Table I. gives the readings of a few fluids w were examined several times. Most of the pati from whom the fluids were taken were treated malaria after the first examination of the f It is interesting to note that in this series of cases colloidal reactions were very seldom altered treatment, although the cell count fell rapidl every case, in some almost to within normal li The Lange reaction is given for comparison with B.G. reaction. No relation between clinical impr ment and alteration in the colloidal reactions c be established. Progress seemed to be related r to the number of cells in the fluid, for in those which did not improve after malarial therapy, cell count remained high. It may be of int also to point out that the course of novarsenob which was given to many patients after ma treatment, likewise had no effect on the coll reactions.

TABES DORSALIS.

The results of the test in tabes conformed le one type than those in general paralysis, but a the reaction approximated to that given by the L test. An average reading was 0012321000.

3 cases, three were completely negative. Of these Lange reaction was negative in one case, though Wassermann was positive in cerebro-spinal and blood; in the second, the Lange gave a typical luetic reading, but the Wassermann was negative; whilst in the third, the Lange reading was very low. One case which was diagnosed as a pure tabes, gave the typical paretic reading of 1344444431, with a Lange reading of 5555555554. Later clinical examination revealed mental changes consistent with early paresis. One other case of tabes which gave a paretic response to the B.G. test and complete precipitation in the Lange reaction is still under observation.

The duration of symptoms in the cases examined varied from two weeks to 15 years. No case was in the stage of remission so far as could be ascertained. Lumbar puncture was usually done within a week of admittance to hospital, and inquiries as to progress of symptoms after the fluid had been examined invariably elicited the reply that patients felt better since they had been in hospital. The duration of symptoms bore no relation whatsoever to the colloidal reactions of the cerebro-spinal fluid. Whereas the most acute case, with a history of two weeks' diplopia and paraplegia, gave a Lange reaction of 4544443221 and a B.G. reaction of 1323421000, two other acute cases, one of six weeks and one of eight weeks' duration, gave readings of 0111000000 and no change respectively in the Lange reaction and no change in the B.G. reaction. On the other hand, a chronic case of ten years' standing gave a Lange reading of 4555553210 and a B.G. reaction of 1444421000. There was no suggestion of a fresh acute attack in this case.

It was felt that no useful purpose would be served by testing the B.G. reaction on the large number of completely negative fluids from patients with disseminated sclerosis which we examined by the Lange reaction. The total number of fluids we examined from patients with this disease during this investigation was 53. Of these, 27 gave a Lange reaction containing one or more readings of 2, and 19 were tested by the B.G. reaction, there being insufficient fluid available in the other eight cases to carry out the test. Twenty-six cases gave a completely negative Lange reaction. Two of these were tested by the B.G. reaction as controls. Table II. gives our findings in the 21 cases tested. It will be noted that in six cases the reaction is completely negative. It will also be noted that the colloidal reactions are independent of the duration of the disease.

As the examination of the fluids was carried out soon after admission to hospital it is not possible to say what effect treatment may have on the colloidal

CEREBRO-SPINAL SYPHILIS.

Slight precipitation up to the amount expressed by the figure 2 was found in most cases of cerebro-spinal syphilis. Two typical readings were 1112110000 and x001211000. When the Wassermann reaction was negative the B.G. reaction was negative also. With one exception no fluid in this group gave a reading higher than is expressed by a 3. The exception was a case in which the diagnosis may have to be reconsidered.

The patient is a young woman of 28, whose symptoms and signs point either to cerebro-spinal syphilis (there is a suspicious history of two stillbirths), or to disseminated sclerosis. The Wassermann is negative in the cerebro-spinal fluid and blood, whilst the Lange reading is of the paretic type, 5543321000, and the B.G. reaction is 2444442000. On these laboratory findings it seems more probable that the case is one of disseminated sclerosis.

DISSEMINATED SCLEROSIS.

In view of the interest which is being centred on this disease at the present time, we propose to discuss in some detail the results we obtained in the 21 cases which we examined by the B.G. test, and to refer also to the Lange reaction in these cases.

reactions. A single observation is of no value, but as a matter of interest, the patient A. B. (Case 20), whose condition was of long standing, and who had had several courses of arsenic injections, gave one of the strongest readings of the series, both in the Lange and B.G. reaction. The B.G. reaction does not seem to be so sensitive as the Lange reaction in this disease. In only five cases, less than 25 per

Abbreviations as in Table I.

cent., was there complete precipitation in any tube, and in only three cases was there a typical paretic response. The proportion of cases giving a paretic response in the Lange reaction was also not very high. In the series of 21, 7, or 33 per cent., showed this reading.

OTHER DISEASES OF THE NERVOUS SYSTEM.

Brief reference must be made to other conditions in which a positive reaction may be given by the B.G. test. These are conditions in which the protein content of the fluid is exceptionally high. In a case of polyneuritis, with a protein content of 1 per cent. and a Lange reaction of 4555422222, the B.G. reaction was 4411000000. Certain cases of spinal compression with a very high total protein gave partial precipitation, the first two or three tubes being completely unchanged, and the precipitation taking place in the fifth and sixth tubes. In other cases only the first or the first two tubes were affected. These curves therefore did not resemble those of tabes or general paralysis. In many other cases with a highly albuminous fluid a completely negative reaction was obtained.

SUMMARY AND CONCLUSIONS.

The cerebro-spinal fluids of 140 patients with diseases of the nervous system have been examined by the bi-coloured guaiac reaction. A Lange colloidal gold test has also been done on each of the fluids for comparison with the new reaction.

Our results justify the statement that the bi-coloured guaiac test is of the same practical value as the Lange test in the laboratory diagnosis of neurosyphilis. The bi-coloured guaiac test runs parallel with the Lange reaction in that certain cases of disseminated sclerosis give positive results. It differs from the Lange reaction in that negative reactions may be obtained in spite of great pro increase.

The ease and certainty with which a good coloured guaiac suspension can be prepared f stock solutions gives the test a definite advant over the Lange reaction, since good colloidal g solutions may be difficult to prepare, and there is satisfactory method of testing them except by t reaction to known specimens of cerebro-spinal fl The Lange reaction is therefore only suited to lab tories where a large number of specimens of cere spinal fluid are examined.

While we have not in this investigation exami the B.G. reaction in relation to the better kn mastic and benzoin reactions, previous experie indicated that the B.G. reaction is more sensitive more easy to read, and agrees more closely in results with the Lange reaction.

The disadvantages of the test are: (1) tha comparatively large quantity, 1 c.cm. of cere spinal fluid, is required for the test; and (2) that not possible to judge what the final reaction wil under 12 hours, whereas with the Lange reactio fair estimate may be made after half an hour. these reasons we do not suggest that this test sh replace the Lange test in the routine examina of the cerebro-spinal fluid. But when diffic arises in the preparation of a good colloidal reagent, the bi-coloured guaiac test may substituted, or may, owing to its more stan nature, be used as a control for the Lange test.

We desire to thank the Medical Staff of the Nat Hospital, Queen-square, for permission to refer t clinical records of cases in the hospital.

THE ÆTIOLOGY OF CHOLECYSTITI

BACTERIOLOGICAL OBSERVATIONS.

BY BRYAN WILLIAMS, M.B. EDIN.,

VANS DUNLOP SCHOLAR, AND ASSISTANT IN THE BACTERI DEPARTMENT, UNIVERSITY OF EDINBURGH;

AND

D. G. S. McLACHLAN, M.B. EDIN.,

LECTURER IN BACTERIOLOGY IN THE UNIVERSITY OF EDINB

BEFORE 1892 gall-stones were supposed t produced by simple chemical precipitatio cholesterol as a result of hypercholesterolæmia that year, however, Naunyn showed the impor of infection in the formation of stones, and adva his theory of a "lithogenous catarrh" of the bladder. Since then, the importance of infecti gall-stone formation has been generally admitted Moynihan has picturesquely described how a gall- may be a tombstone erected to the memory organism still living inside.

Earlier investigations were directed rather tov the occurrence of organisms in the bile, and mer of the coliform group were the chief ones isol Owing to the prevalence of typhoid fever at th of the last century, much attention was pa typhoid cholecystitis. More recently, the orga of the enteric group have been encountered less frequently in this condition. As will be below, *Bacillus paratyphosus* B was isolated once in the present series of 106 cases.

Rosenow,[1] in 1916, was the first to stress the importance of the streptococci, and also the need for examining the wall of the gall-bladder in order to obtain an adequate idea of the organisms present. In a series of 47 cases he demonstrated the presence of streptococci, either alone or in combination, in 76 per cent. of cases in which the wall was examined. *B. coli* and other organisms occurred less frequently. He found that these organisms had a very marked tendency to localise electively in the gall-bladder of experimental animals. Thus in 53 animals, the gall-bladder was attacked in 79 per cent. of cases, and other organs much less frequently. These results were obtained with freshly isolated strains, and as the result of inoculating considerable quantities of culture. A. L. Wilkie [2] has recently claimed similar results. In 50 cases he isolated streptococci from the cystic gland in 86 per cent., and from the gall-bladder wall in 42 per cent. The bile, on the other hand, was generally sterile. He considered that the streptococci were susceptible to the action of bile, and found that they had considerable affinity for the gall-bladder of rabbits, invariably producing a progressive chronic cholecystitis.

The present work was undertaken with the object of investigating the occurrence of streptococci in cholecystitis and their biological characters, and also their power of attacking the gall-bladder of animals on intravenous injection. Attention has been directed towards cholecystitis rather than cholelithiasis. It is impossible, however, in any experimental work to dissociate the two conditions. Undoubtedly either condition may occur without the other, and either may predispose to the other. In the great majority of cases dealt with clinically, however, we find that the two conditions coexist, although of recent years there has been a tendency to operate on earlier cases, especially since the introduction of cholecystography.

Technique of Present Investigation.

Material from 106 cases of cholecystitis had been examined. The following technique was observed when specimens were taken at operation.

After removal of the gall-bladder the cystic gland, when palpable, was dissected off and placed in a sterile test-tube. The clamp on the cystic duct was then replaced by a ligature in order to prevent escape of bile, and the gall-bladder was removed to the laboratory in a covered sterile dish or sterile swabs. In most cases cultures have been made from the specimens immediately after removal from the theatre; on a few occasions an interval of three or four hours elapsed. Other cases where the interval was longer have been excluded from consideration.

In the laboratory the cystic gland was first cultured. With due precautions it was transferred to a covered sterile mortar, minced up with sterile scissors, and emulsified in broth with a pestle. Tubes of warm glucose broth and, in some cases, blood-agar plates, were then inoculated with the emulsion. Cultures were incubated for at least seven days or until growth occurred.

Cultures were also made from the gall-bladder wall. The peritoneum and the layer of subperitoneal fat, which is usually present in chronically diseased gall-bladders, were reflected with sterile instruments and the so-called "sub-mucous" coat exposed. Strips of this were dissected away, without opening the lumen of the gall-bladder, and cultured in the same way as the cystic gland. The lumen of the gall-bladder was next opened, and cultures made from the bile or other contents or from the surface of the mucous membrane or stones.

In cases in which the wall was only slightly thickened—and there were many of this nature in the series—it was not found possible to obtain an adequate amount of the sub-mucous layer for culture without opening the lumen of the gall-bladder, and in these circumstances fragments of the whole thickness of the wall were used. In order to kill any organisms present on the surface of the tissue in the bile, several of the fragments were cultured after being washed with sterile saline, or after momentary exposure to boiling water or brief immersion in spirit followed by washing with saline.

Cultures were made from gall-stones after the surface had been sterilised by immersion in spirit and flaming. If large, the stones were cut with a sterile knife and the centre scooped out and emulsified. If small, the complete stone was emulsified.

The media employed were glucose broth, phosphate broth, glucose agar in deep tubes, and rabbit blood-agar plates. Glucose brain broth was used in some cases. Rosenow has stressed the importance of fluid media for supplying all grades of oxygen tension. Primary broth cultures were purified by plating out on a blood-agar plate. In a few cases organisms resembling *B. subtilis* and unidentified cocci of the nature of sarcinæ have been obtained. These have been regarded as contaminants.

Classification and Findings.

The classification of the gall-bladders examined has presented some difficulty, owing to the enormous variation in the pathological changes present. Most classifications of cholecystitis seem to be needlessly complicated, and we have adopted the simple but convenient divisions of acute cholecystitis, chronic cholecystitis with or without stones, and cholesterosis.

ACUTE CHOLECYSTITIS.

The four cases grouped under the heading of acute cholecystitis derive their place rather from clinical reasons. All were admitted as emergency cases, three being operated on at once and the fourth within a few days. Two of the patients subsequently died. Gross inflammation was present in all, the gall-bladder in two cases being gangrenous. Stones were removed in three cases.

TABLE I.—*Acute Cholecystitis.* (*Four Cases.*)

Case.	Diagnosis.	Gall-bladder wall.	Contents.
1	Acute cholecystitis with stones.	*B. welchii.*	*B. coli.*
2	Gangrenous cholecystitis with stones.	No growth.	*B. coli.* Enterococcus. *B. welchii.*
3	Acute cholecystitis, gall-bladder being partly gangrenous.	*B. welchii.*	*B. coli.*
4	Gangrenous cholecystitis with stones.	*B. coli.*	,,

The bacteriological findings in each case are shown in Table I. It will be noted that *B. coli* occurred in every case and *B. welchii* in two cases.

CHRONIC CHOLECYSTITIS.

The second group comprises the great majority of cases. In gross pathology the specimens showed great variation, all degrees of inflammation being represented. Several cases of empyema or mucocele

and a number of cases of stone in the common bile-duct have been included. Many specimens showed evidence of recent inflammation. Stones were present in 72 out of the 93 cases. The results of the cultures are shown in Table II.

CYSTIC GLAND.

The cystic gland, which varied in size from that of a pinhead to a small bean, was examined in 43 cases. In some cases, in which it could not be identified with certainty, the connective tissue from the neck of the gall-bladder was cultured, but as this was never found to give a growth unless contaminated with bile these cases have not been included in the Tables. On several occasions the tissue was removed from the culture tube at periods varying between three and seven hours, on the supposition that there might be some substance in the tissue which inhibited bacterial growth. There was no difference in result, however, between these tubes and others in which the tissue was allowed to remain.

It will be seen from Table II. that streptococci were obtained in eight cases (19 per cent.) and *B. coli* in seven cases (16 per cent.) in which the cystic gland was cultured. It is impossible to exclude contamination of the gland by bile in some cases in which the same organism was obtained from both gland and bile, owing to the exposed position of the gland when the duct is divided. Thus, on four occasions on which a streptococcus was cultivated from the cystic gland a similar organism was also obtained from the bile.

GALL-BLADDER WALL.

The gall-bladder wall was examined in 84 cases, and the presence of streptococci, either alone or in combination with *B. coli*, was demonstrated on 14 occasions (17 per cent.), *B. coli* was isolated in 19 cases (23 per cent.). On seven occasions a streptococcus similar to that found in the wall was obtained from the bile. In three further cases a similar organism was found in gland, wall and bile, and in one other case in the gland and bile. Of the 24 cases in this group in which streptococci were found, in only five were they not found in the bile. In one of these the bile was not examined. In three others streptococci were found, either alone or in combination with *B. coli* in the wall, while *B. coli* was found in the bile. In the tabulation of the results an organism has been considered to be an intramural one if it has been obtained either from the outer coats or from the whole thickness of the wall, when the bile has given no growth, or after sterilisation by one of the methods described above.

The results of the cultures have often been surprising. Occasionally naked-eye appearances are extremely deceptive. It may be stated on the whole, however, as noted by Illingworth,[3] that the specimens most likely to give a growth are those with a thick and œdematous wall.

CONTENTS.

The bile, mucus, pus, or other contents of the gall-bladder or the surface of stones have been examined in 81 cases of chronic cholecystitis, and the results are shown in Table II. Here, again, as noted by Illingworth, naked-eye appearances are very deceptive. A purulent-looking content may be sterile, while thin bile may yield a growth. The important factor, however, seems to be the concentration of the bile. It has been found that thick, tarry bile, so often looked upon with suspicion, is always sterile, whereas white bile is nearly always infected.

Streptococci were isolated from the contents in 21 cases (26 per cent.), in six of which they were associated with *B. coli*. *B. coli* was present in 16 specimens (20 per cent.); two of the coliform strains appeared to be identical with *B. lactis aerogenes*. It is of interest to note that a streptococcus was only isolated once out of the 21 cases in this group in which stones were absent, and in that case it was isolated fro the bile. In one other case in which stones we absent, *B. paratyphosus* B was obtained from t discharge from a gall-bladder sinus. This patie had several months previously suffered from par typhoid fever, and had subsequently developed acu cholecystitis, for which drainage of the gall-bladd was carried out.

CHOLESTEROSIS.

Nine cases of this condition were investigated an the results are shown in Table III. Only those cas showing a general "strawberry" appearance the whole mucous membrane are included under th heading. Stones were present in six cases, two of the being single cholesterin stones.

TABLE III.—*Cholesterosis.* (*Nine Cases.*)

The low incidence of organisms in this condition which is in accordance with the recent findings Illingworth [4] and Nickel and Judd,[5] is of interes when we consider that inflammatory changes some degree are nearly always present. Thus i 35 cases of Illingworth's inflammatory changes we only once absent.

Nature of the Organisms Isolated.

The classification of streptococci into hæmolytic an non-hæmolytic types is now generally accepted, an all the organisms under consideration fall into th latter type. A few of them produced tiny zones hæmolysis on blood-agar, but none of them showe true "beta" hæmolysis. It is possible to a certai extent to tell from the general characters of a no hæmolytic streptococcus its probable natural locatio in the body.

Of the eight strains isolated from the cystic glan four corresponded definitely to enterococci in the characters of heat-resistance, tolerance of a mediu containing bile, and ability to split æsculin. Th other four resembled salivary streptococci. Of t strains obtained from the gall-bladder wall seven we enterococcal in type, and of 23 strains cultivated fro the bile, nine belonged to this group. Of the remainin strains, some resembled salivary types while the re were of the nature of *gamma* streptococci. Thomso and Thomson [6] have recently emphasised the valu of Warren Crowe's medium in differentiating strepto cocci. A systematic study of all strains has not bee carried out on this medium, but a certain numbe have been tested and have been found to present variety of colony appearances. This result is i agreement with the other evidence regarding th biological diversity of our streptococci.

A serological examination of the strains isolate showed that there was considerable antigenic hetero geneity. Agglutinating antisera were prepared b immunising rabbits with three strains of *Streptococcu viridans* previously isolated from the cystic glan Two of these strains were serologically identical, an were quite distinct from the third strain. Agglutina tion and agglutinin-absorption tests were carried ou according to the technique described by McLachla and Mackie.[7] These tests indicated that one of th

trains examined was related antigenically to two of he cystic gland strains, but was not identical with hem, as it did not completely remove the agglutinin rom the sera. A second strain likewise showed a artial antigenic similarity to the third cystic gland train. The remainder of the viridans strains and all he enterococci which were tested did not react with hese sera. Agglutinating sera were prepared for wo strains of enterococcus, which were themselves erologically distinct as judged by agglutinin-bsorption tests. None of the enterococci or other treptococci which we studied reacted in a significant nanner with these sera.

Of the other organisms isolated, *B. coli* has occurred nost frequently and occupied the most important lace. With few exceptions, it has shown the bio-ogical characters of "typical *B. coli*." In two cases f cholecystitis, *B. lactis aerogenes* was isolated, and n a third case a non-lactose-fermenting variety of *3. coli* was obtained. The occurrence of *B. welchii* s of considerable interest in view of recent work on he use of *B. welchii* serum in acute abdominal onditions. It seems to have been first described in holecystitis by Gilbert and Lipmann [8] in 1904, and as since been found by numerous observers. In he present work it was found in six cases: in the land once, in the gall-bladder wall five times, and n the contents twice.

Animal Experiments.

In order to test the power of the organisms isolated o localise electively in the gall-bladder of experimental nimals, a number of intravenous injections in rabbits rere given. The organisms used were streptococci, *3. coli*, *B. paratyphosus* B, and *Staphylococcus aureus*. he strains tested were injected as soon as possible fter isolation.

Twenty-four-hour broth cultures were employed, and the njection given into the ear vein. Two methods of dministering the organism were practised. In the first nall doses of 300 to 500 million organisms were given t weekly intervals, as advocated by A. L. Wilkie. Up o nine injections were given. In the second method, a ngle large dose of 5000 to 10,000 million organisms was iven, and the animal was killed in a few days if the injection id not prove fatal. This is the method practised by Rosenow. The enormous doses originally employed by Rosenow, such as the deposit from 45 c.cm. of a broth culture, rere not used. Rosenow has stated (1928) [9] that in his iore recent work on elective localisation he has only mployed one-tenth to one-fifth of the quantities formerly njected.

When the injection did not prove fatal the animals were illed by chloroform at periods varying from a week or two p to several months. All the viscera were carefully xamined at once, together with several joints, and usually lso the brain. Cultures were made from the heart blood, ile, gall-bladder wall and joints, and from any organ howing a lesion.

The appearance of the healthy rabbit's gall-bladder was etermined from a number of examinations carried out on nimals killed for other purposes. It is a very delicate ructure, bluish in colour, and with a translucent wall. t can be moved freely in a sideways direction. The bile of variable colour, but is thin and free from granules.

Thirty-one rabbits received injections of strepto-occi by one of the two methods described above. Twelve were injected with strains derived from the ystic gland, seven with gall-bladder wall strains, leven with bile strains, and one with a streptococcus erived from a gall-stone. After the injection of these rganisms, a gross lesion of the gall-bladder developed n only one rabbit, and there was a doubtful lesion in nother animal.

In the first case the animal was inoculated with 7 c.cm. f a broth culture of a poorly growing viridans streptococcus olated from the bile and gall-bladder wall of a case of hronic cholecystitis. The animal remained apparently ell and was killed after a week. The gall-bladder was found to be thick and œdematous, and covered with fibrin. A streptococcus with the same biological characters as the strain injected was recovered from the wall. Microscopic examination of sections of the gall-bladder wall showed considerable œdema of the tissue and infiltration by large numbers of polymorphonuclear leucocytes. The epithelium had desquamated, and streptococci were found in the wall after prolonged search. Intravenous injections of the organism recovered from the gall-bladder did not produce cholecystitis in other rabbits.

In the other case in which a slight lesion of the gall-bladder was found, the animal had been injected two days previously with 7 c.cm. of a broth culture of *S. viridans* isolated from a cystic gland. The gall-bladder wall was found to be slightly œdematous, but cultures from it and also from the bile were negative.

Lesions in other organs were sometimes encountered. Thus, hæmorrhages in the stomach were found with great frequency, and in one case large vegetations were produced on the aortic valves. In no case was arthritis noted.

B. coli.—Six strains of *B. coli* were injected intra venously in different rabbits, the organisms having been isolated from the bile of patients with chronic cholecystitis in three cases, from the gall-bladder wall in two cases, and post mortem from the heart blood of one of the rabbits in one case. In one animal a gross lesion of the gall-bladder was found. The animal died two days after the injection. The gall-bladder wall was thickened, and the bile was turbid and filled with numerous tiny yellow granules, together with several black granules. *B. coli* was isolated from the bile.

B. paratyphosus B.—Three rabbits received intravenous injections of this organism. Two animals were inoculated with the strain isolated from the discharge from a gall-bladder sinus, and died after two and three days respectively. In both there were pneumonia and general congestion of the organs, and in one the gall-bladder was acutely inflamed and contained several small granules. *B. paratyphosus* B was recovered from the bile of both rabbits. The third rabbit was injected with a strain which had been isolated from sewage, and died three weeks after the injection. At autopsy the gall-bladder was whitish and thick and full of soft brownish concretions. *B. paratyphosus* B was recovered from the bile and gall-bladder wall.

Staphylococcus aureus.—Intravenous injections of this organism did not lead to cholecystitis.

DIRECT ATTACK ON THE GALL-BLADDER.

As intravenous injections of streptococci appeared to be followed in only a small proportion of cases by a definite cholecystitis, attempts were made to determine the localisation and multiplication of organisms in the gall-bladder by traumatising the viscus and inoculating cultures intravenously. The effect of trauma by itself was controlled. In carrying out this procedure a laparotomy was performed under ether anæsthesia, and the gall-bladder was gently rubbed and squeezed with the finger. Immediately after the operation an intravenous injection of streptococci was given, and repeated once or twice. The strains used had been isolated from the cystic gland, from the bile, and from the mouth of a healthy person. This procedure was carried out in four rabbits; in none of these was there any pronounced change in the naked-eye appearance of the gall-bladders. Trauma without injection was carried out in five rabbits. In two of these the gall-bladder was traumatised once, and in one the gall-bladder showed no change after an interval of two months. In the other the animal died after 19 days, and at autopsy the gall-bladder was found to be thickened and full of purulent material, from which *B. coli* was isolated.

In two other animals the gall-bladder was traumatised twice with an interval of three weeks between each operation and the animals were killed after two months. In both there was definite thickening of the gall-bladder wall. In the fifth rabbit the gall-bladder was traumatised four times at weekly intervals. The animal was killed two months after the first operation, and the gall-bladder wall was found to be thickened and surrounded by adhesions, with its lumen full of inspissated material.

The effect of injecting streptococci into the wall of the gall-bladder was also investigated. A very fine needle was used for this purpose. It was found necessary to give very small doses, as in some cases leakage of the suspension into the peritoneal cavity occurred, with subsequent peritonitis and death. This procedure was carried out in three rabbits and resulted in a slight thickening of the gall-bladder wall. A similar condition was also observed in two control animals in which sterile saline was used instead of the suspension of organisms.

Summary.

The bacteriological and experimental work detailed bove was originally undertaken with the object of investigating the rôle of streptococci in inflammatory disease of the gall-bladder, and also their power of "elective localisation," or, in other words, their selective affinity for the gall-bladder tissue of animals. As the work proceeded, streptococci were found in only a small percentage of cases, as contrasted with the incidence reported by certain other workers. Thus out of 106 cases examined, streptococci were found in 26 cases, and *B. coli* in 28 cases. Certain other facts that were in disagreement with some recent ideas on the ætiology of cholecystitis also became apparent. Thus, out of the 26 cases in the series in which streptococci were found, they were present in the bile in 21 cases. In one of the other five cases the bile was not examined; in three of them streptococci were found either alone or in combination with *B. coli* in the gall-bladder wall, whereas *B. coli* alone was found in the bile. It is thus possible that in these cases streptococci were present in the bile but were outgrown by *B. coli* in culture. In the remaining case, streptococci were found in the cystic gland, while the gall-bladder wall and bile were sterile. The high incidence of infection of the bile with streptococci is thus very striking in those cases in which this organism was present, and remains so, even if we exclude the cases of acute cholecystitis and of calculus in the common bile-duct, in which the bile is almost invariably infected. It must also be realised that any contamination of the cystic gland or outer coats of the gall-bladder wall by bile in the course of operation must increase the number of cases in which these structures are apparently infected. In our experience bile has not been inhibitory to the growth of the majority of the types of non-hæmolytic streptococci which we have encountered in these conditions; this is in accordance with the recent work of Nickel and Judd, and contrary to the findings of A. L. Wilkie.

It was also noted that a large percentage of the streptococci isolated were undoubtedly of the "enterococcus" type, which is found naturally in the bowel. The others belonged to types which are known to occur both in the mouth and in the bowel. In several cases undoubted enterococci were isolated from the cystic gland and from the gall-bladder wall. In each case also in which streptococci occurred in more than one site the strains isolated were found to have similar characters, this being in disagreement with the findings of Wilkie, who described cultural differences between the streptococci isolated fro the cystic gland and the bile in the same case. was also found in some cases that mixtures streptococci and *B. coli*, both growing freely, we obtained from various situations.

All these facts seem to indicate that the origin site of the streptococci isolated was the same as th of *B. coli* (i.e., the bowel) and that, therefore, t route of infection to the gall-bladder was presumab the same. There would seem to be no evidence th the streptococcus is the primary invader and *B. coli* t secondary invader. The part played by both in t invasion of the gall-bladder seems to be simil We do not feel justified in concluding from our wo however, that any of the organisms we have isolat is the primary factor in the production of infla matory changes in the gall-bladder. It is conceivab that they may all play merely the rôle of seconda invaders when once some pathological change, to or biochemical, has already commenced in the ga bladder.

Further experiments are in progress with the obj of determining the route by which organisms rea the gall-bladder. So far, however, our anim experiments have not supported the idea th organisms usually reach the gall-bladder by means f the systemic circulation, nor have we been able sustain the theory that the organisms isolated in t condition have the power of localising electively the gall-bladder of animals on intravenous injecti It has been already noted that out of 31 rabb injected intravenously with streptococci, only t showed a gross lesion of the gall-bladder. Any acti of these organisms on the gall-bladder, therefo appears to be purely a chance one, and entir non-specific.

Few theories in medical science have been so mu debated as that of "elective localisation." On t whole, Rosenow's results have not been genera confirmed. Holman[10] has recently made a ve critical analysis of Rosenow's figures. He has sho that there is very little difference in the percenta of lesions produced in various organs with spec and with non-specific strains, and that indeed many cases the percentage is higher with the n specific than with the specific strains. Gay however, has also analysed Rosenow's figures, w the opposite result. He finds that among 8 animals injected with 220 strains, gall-bladder lesi were produced in 80 per cent. of cases with spec strains, and only in 11 per cent. with non-spec strains.

It would be absurd to criticise the whole theory f elective localisation on the basis of the work descri in this paper, but, at any rate as regards the g bladder, we have not been able to support it.

Conclusions.

1. Material from 106 cases of cholecystitis h been examined. Streptococci have been found the cystic gland or gall-bladder wall in 16 per cent. these and *B. coli* in 20 per cent. Streptococci ha been found in the contents in 20 per cent. and *B. coli* 19 per cent. 2. The streptococci isolated have b largely of the type which occur normally in bowel. 3. No evidence has been obtained th *B. coli* is merely a secondary invader, and that streptococci are the primary invaders. The rôle both, whether they be primary or secondary invad seems to be similar. 4. The organisms isolated ha very little power of localising electively in the g bladder of experimental animals.

We should like to express our thanks to Prof. Mac

for his constant help and guidance throughout this work. We should also like to thank Prof. D. P. D. Wilkie, who has been at considerable pains to provide us with the greater part of the material used, and who has given us much other assistance and encouragement. Mr. Henry Wade, Mr. J. W. Struthers, Mr. J. M. Graham, and Dr. W. R. Martine have also kindly provided us with material. Mr. C. F. W. Illingworth has given us much useful advice.

The work has been done during the tenure of a Vans Dunlop scholarship by one of us (B. W.). Part of the expenses have been paid by a grant from the Moray Fund.

THE PYROGENETIC ACTION OF SULPHUR IN OLIVE OIL.

BY W. H. SHILVOCK, B.SC., M.B. BIRM.,

ASSISTANT MEDICAL OFFICER, RUBERY HILL MENTAL HOSPITAL, BIRMINGHAM.

Schroeder [1] and Harris [2] have reported on the use of sulphur in olive oil as an agent for the treatment of general paralysis and other psychoses, and point out that pyrexia follows its administration. I have used a preparation of sulphur in olive oil ("Colsul") made by the Crookes Laboratories, and have noted its effect in producing pyrexia. No claim is made here that this preparation is a panacea which will cure these disorders.

Control injections of collosol sulphur in water (0·1 per cent. sulphur), collosol calcium, and sterile olive oil, all prepared by the Crookes Laboratories, did not cause a rise of temperature.

METHOD OF TREATMENT.

The technique adopted is similar to that used by Schroeder and Harris. The injections are given intramuscularly into the outer side of the thigh in the morning. The temperatures are recorded every two hours for the first eight hours, and then every 30 minutes for the next two hours, and then at 15-minute intervals until the acme is reached. When this has occurred the temperature is taken every 30 minutes and then every two hours until it is normal again.

The colsul used has been supplied in 5 c.cm. phials. It is warmed before injection. The first dose is half a c.cm., and the doses are increased by half a c.cm. every alternate day for a course of ten injections, the largest dose thus being 5 c.cm. These doses are smaller than those used by the previous reporters but produce similar pyrexial reactions. A second series of injections has been given within three weeks of the completion of the first, the interval allowing time for various investigations to be made on the effect of the treatment.

[1] Schroeder, Knud: THE LANCET, 1929, ii., 1081.
[2] Harris, N. G. Ibid., 1930, i., 1068.

EFFECT OF THE INJECTIONS.

Eighteen cases have so far been treated, nine of general paralysis and nine of non-syphilitic functional mental disorder. Although the doses have been smaller there has been much more local discomfort than Schroeder claims to have noted, but this gradually passed off in the course of a few days. As a rule the temperature rises gradually, reaches its maximum in about 12 hours, and returns to normal in periods varying from 12 to 72 hours. In one case it continued over a period of five days from the initial injection, but usually it is normal within 24 hours. The temperature charts seem to show that, with the increase of dose, there is a corresponding increase of pyrexia, but this is not constant even with the same type of mental disorder, probably because of the individual peculiarities of the response of thermogenic centres. The duration of the pyrexial period depends also on the individual. The highest temperature recorded in this series of cases was 105·4°, this being at the ninth injection of 4·5 c.cm., but most of the cases gave maximum pyrexias of about 104°. In this therapy, as has also been noted with T.A.B. vaccine given intravenously, there may be secondary rises of temperature following what appears to be the fall from the acme induced by the agent itself, and these have been observed in the majority of the charts. These secondary rises delay the fall of temperature and are more in evidence when the temperatures are higher.

The extent of the pyrexial swing from subnormal or normal level at the time of injection was also found to vary with corresponding injections in different patients. The maximum alteration of temperature noted has been 7·8°, and occurred in a case at the end of a course following the injection of 5 c.cm.

The valuable property of the preparation is the comparatively small disturbance of the circulation which is associated with such elevations of temperature. In no case has a pulse-rate above 120 per minute been recorded, and nearly always the respiration ratio is approximately normal; for example, a patient after an injection of 1 c.cm. gave a maximum temperature of 104·2°, a pulse-rate of 94, and a respiration-rate of 24. Little deleterious effect on the peripheral circulation has been noted, pallor and cyanosis having rarely been seen.

In seven cases definite rigors have been noted, occurring from 30 minutes to 4 hours before the maximum temperature. These are minor compared with those induced by malaria or T.A.B. vaccine (given intravenously). Most of the cases had had treatment for dental sepsis and nasal sinus infection before the injections. In two cases focal reactions occurred in areas of sepsis for some days after injection—e.g., antra of Highmore which had previously given clear returns on irrigation again became mucopurulent. In one case—a general paralytic—definite herpetic vesicles appeared on the hands after the third injection. This patient had already had T.A.B. vaccine and malarial pyretotherapy. No bowel disturbance has been noted and vomiting—and even that mild—in only one case. Profuse sweating has been present in all the cases, the extent depending on the pyrexia induced.

ADVANTAGES.

No patient has been made worse, either mentally or physically. Abscesses have not appeared at the site of injection. Good pyrexial reactions follow, but their extent may be dependent on the patient, apparently on the activity of the thermogenic centre. Thus, one patient regularly had pyrexias of 105°

with malaria and gave the same response to colsul. Another, however, regularly gave poor pyrexias with malaria but much better with colsul. The pyrexias follow the injection, and there is no delay due to an incubation period. No additional disease is induced, nor are agents required to control it. Therefore a febrile state can be induced at any time of the year and the pyrexias can be timed as desired, and produced by intramuscular injection. The agent seems to cause a focal reaction in the areas of chronic sepsis. This latter reaction indicates its value and probable mode of action in the treatment of mental disorder.

My thanks are due to my medical superintendent, Dr. T. C. Graves, and to Mr. J. F. Ward, of British Colloids, Ltd., for help received and for the preparation of the material for control injection.

SULFOSIN THERAPY IN GENERAL PARALYSIS OF THE INSANE.

BY WILLIAM G. PATTERSON, M.D. EDIN., M.R.C.P. LOND., D.P.H.,

AND

S. R. L. SWITZER, M.R.C.S. ENG.,

ASSISTANT MEDICAL OFFICERS, CLAYBURY L.C.C. MENTAL HOSPITAL.

IN 19 cases of general paralysis of the insane we have administered sulfosin Leo—a 1 per cent. suspension of sulphur in olive oil—according to the method originated by Schroeder.[1] We employed this method without modification, and adopted the graduated dosage, beginning at 1 c.cm. and increasing by 1 c.cm. each time to a maximum of 10 c.cm.; in two of our patients the course was stopped at the seventh and the eighth injection respectively owing to increasing debility. We can record no such dramatic results as would justify the publication of full clinical records of cases observed for a maximum of only six months. But it seems desirable to record certain of our findings. We begin by tabulating the average maximum temperatures obtained in each case during the courses of sulfosin.

Case.		Case.	
1	102° F.	14	1st course, 101·9° F.; 2nd „ 100·6° F.
2	101·3° F.

Serological tests were made at the Maudsley Hospital, and the results of the Wassermann reactions are given in five increasing strengths as follows:—Blood: +6, +7·5, +10, +15, and +30. Cerebro-spinal fluid: +2, +3, +6, +15, and +30.

On the whole the following table shows little serological change immediately after sulfosin therapy in 19 cases, of whom 13 had a single course, 5 two courses, and 1 three courses. Schroeder, despite his general dictum that the serological changes may not become manifest until a considerable time after the course of sulfosin, gives details of case after case in which very marked serological changes developed during, or apparently immediately after, a single course of sulfosin. He also describes most rapid and dramati clinical results in the majority of his patients. Ou results, both clinical and serological, are comparativ failures.

B.W. = blood Wassermann. C.S.F.W. = cerebro-spinal flu Wassermann. C.S.F.L. = cerebro-spinal fluid Lange. S. = cour of sulfosin. S+s+b = course of sulfosin synchronous wi course of sulfarsenol and bismuth. — = Not done.

The justification of this early report is that consider all weak links in sulfosin therapy, the val of which is still sub judice, should be detected a eliminated as soon as possible; and our main purp is to point out a possible weak link. Schroede paper gives the impression that the typical pyrex in his cases after each dose of sulfosin was 104° or 105° F.

"It is important to know the maximal temperatu

[1] Schroeder, K.: THE LANCET, 1929, ii., 1081.

ained, as the dosage of the injections is dependant on s, since the aim is a rise of temperature to about 104° F. more. One begins with a small test dose (1 c.cm.) and reases the dose by 1 c.cm. up to 10 c.cm., as the nperature will increase with the increase of the se. The next injection is given when the temperature s fallen to normal—usually after 24 hours—so the ection is given about twice a week."

In our series, however, the typical pyrexia was not 4° or more, but 101° or 102° F.; pyrexias of 105° d 104° did occur, but only once and ten times spectively in about 250 injections; moreover, Case 6, in his single course of sulfosin, provided e 105° pyrexia and six of the 104° pyrexias, the portion of high temperatures in the other 18 tients was even lower than the first figures imply. hatever the value of sulfosin may be in general paralysis, it is conceivable that this value depends on the height of the pyrexia produced by each dose; we therefore suggest, as Schroeder himself has proposed already, that in sulfosin therapy one should aim at securing in each patient consecutive pyrexias of 104° or 105° F., such as occur in induced malaria. Our experience is that the recommended ten-dose course of sulfosin, beginning at 1 c.cm. and increasing 1 c.cm. at a time to 10 c.cm., fails to produce such pyrexias, not in the isolated atypical case but in the great majority of cases.

We wish to thank Dr. G. F. Barham, medical superintendent of Claybury Mental Hospital, for permission to carry out and publish this research, and we also acknowledge our great indebtedness to the staff of the Maudsley Hospital laboratory, where the numerous serological examinations were performed.

CLINICAL AND LABORATORY NOTES

A CASE OF PITUITARY CACHEXIA.

By Jane W. Stocks, M.B. Glasg.,

SSISTANT MEDICAL OFFICER, HOLLYMOOR MENTAL HOSPITAL, BIRMINGHAM.

The following case is of interest for the extreme ntal apathy and muscular atonia which are probably erable to a disordered pituitary gland. Such ndromes are, in varying degrees, common in mental spitals. The association with pituitary disturbance substantiated by its resemblance to published ses of pituitary cachexia (one of which had an scess separating the anterior lobe of the pituitary nd from the posterior lobe). The Joint Board Research for Mental Diseases, Birmingham, ve found post mortem, large masses of colloid the pars intermedia of the pituitary in many ses of mental disorder.

THE CASE RELATED.

The patient, a single woman, aged 33, was mitted on Jan. 18th, 1928. She had had several tacks of influenza before an operation in May, 1919, removal of a cystic diseased ovary; after this eration she had been almost continuously in bed til her admission here. She was stated to be ffering from "neuritis and neurasthenia" during at period and had psycho-therapeutic treatment. February, 1927, she had two attacks of influenza d in April, 1927, her father was accidentally led. From then on there appeared to be an acerbation of the symptoms, her condition became ogressively worse, she became very emaciated, fused her food, and said she wanted to die.

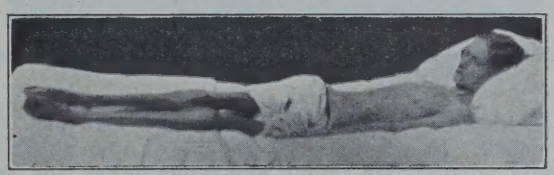
There was no case of psychosis in the family story. The patient had been at school until the e of 14, reaching standard VII., and had subsetently worked in a factory.

Mental state on admission.—She was dull and apathetic, t suspicious and determined as far as was in her power to ist nursing attention. She had visual and auditory llucinations; she stated that she "saw dreadful faces," at "something had happened to her" and that "this ered everything"; she felt "she had no head"; voices ld her not to eat her food, people sneered at her and sjudged her; she thought she was ill and could not get ll but would not die. She had previously threatened to ll herself by hanging and by drowning.

Physical state on admission.—She was extremely emaciated, ighing only 4 st. 10 lb., about half her average weight ig. 1). Her muscular system was almost completely onic with the exception of the muscles of mastication, hich were in spasm, great difficulty being experienced in opening her mouth for feeding purposes. Her extremities were cyanosed; the deep reflexes were increased and there was bilateral ptosis, dental caries, and gingivitis. Menstruation had been regular until nine weeks before admission, since when it had been in abeyance.

Course.—For many weeks the patient lay in bed in a state approximating to that of a catatonic stupor. On account of the septic condition of her mouth she was given anti-streptococcal serum daily in increasing doses for a week, the last dose being 50 c.cm. She showed no interest whatever in her surroundings and had to be forcibly fed; the muscular system remained completely atonic, there was no control of the sphincters, and the temperature was subnormal, varying between 96° and 97·6° F., the average being below 97°. The Wassermann reaction was negative. The mental and physical condition slowly deteriorated until March 11th, 1928, and the weight fell to 4 st. 5 lb.

FIG. 1.



Showing extreme emaciation of the patient on admission to hospital.

On account of the atonic condition and suspected pituitary disturbance, the patient was given 1 c.cm. of pituitrin twice daily from March 11th, 1928, till June 26th, 1928 (once daily during the latter part of the time). She now showed a decided improvement in the muscle tone and general circulation and some signs of interest in her environment, and would take her food without resistance from a particular nurse. Her eyes were fixed and staring and she was unable to close them, even when stimulated by a bright light or a loud noise or by sudden movement of the hand over her face. On August 7th, 1928, two septic teeth were extracted by Mr. T. Yoxall, and similar dental treatment was carried out at monthly intervals until a complete clearance was effected. She continued to improve, and on Sept. 15th, 1928, she was able to sit up in a chair. She could reply to questions by monosyllables only after a long latent period, but her face was mask-like and her hair was limp and lustreless.

Gradually improvement took place and she was able to perform simple movements. She could hold a spoon, and when taught to feed herself continued the act in an automatic manner, not, however, stopping

when the plate was empty or even removed. During this period she was unable to accommodate for near vision; she exhibited a curious affection of locomotion, being able to walk when assisted to start but unable to accelerate, retard, or make even a slight turn. In this state she walked into the wall or any obstacle. By Christmas, 1928, she began to show a little more interest in her surroundings, although it was not for another six months that she was able to move her eyelids voluntarily. Menstruation returned in February, 1929, and by the end of May muscle tone

FIG. 2.

Showing the stuporose condition of patient before treatment contrasted with her appearance on recovery.

had improved sufficiently to enable her to pick up a pencil. It was not until the end of June that she could approximate thumb and index-finger, and the grip was still weak; by the end of July she could approximate thumb and little finger and her grip became quite good. She continued to improve, the last noticeable return of voluntary movement being that of rising from a sitting position. Previously she could not initiate this process until her arm was touched.

She was discharged recovered on Nov. 14th, 1929. At that time she was able to carry on a conversation with normal intelligence without psychomotor retardation. She had insight into her illness, helped in the ward, could carry piles of plates without mishap, took an interest in her environment and in the social events of the hospital, could dance well, and was able to write a sensible well-penned letter on Sept. 23rd, 1929. Her facial tone, mobility, colour, stance, and carriage of body were that of a normal person and contrasted to an extraordinary degree with the atonic stuporose condition in which she had so long existed (Fig. 2).

COMMENT.

Pituitary cachexia, as described by Simmonds in a case of necrosis of the anterior pituitary by a septic embolus, showed the clinical features of cachexia, senility, loss of pubic and axillary hair, and general nervous disturbances. Thirty-four such cases have been described up till the year 1928. Amongst the various symptoms ascribed to the condition this case presents a parallel in the following:

(1) Cachexia; from a normal of 8 st. 8 lb. her weight dropped to 4 st. 5 lb., and later rose to 9 st., a difference of 65 lb. (maximum published, 110 lb.: Simmond's case). (2) She presented a wrinkled, senile appearance. (3) Pubic and axillary hair w definitely scanty. (4) General nervous disturbance v severe, necessitating her certification and admiss to a mental hospital. (5) Trophic vaso-motor s disturbances were a marked feature; there v extreme cyanosis of the extremities and bedso were threatening on admission. (6) The skin v dry, rough, and scaly. (7) Muscular weakness v extreme. (8) She had a subnormal temperatu ranging between 96° and 97·6° F. (9) Her bl pressure was obviously very low, the systolic press being roughly estimated at 90 mm. (10) Gas disturbance was shown by the persistence of undiges food (as evidenced by stomach washings bef a tube feed) for 18 hours or more. (11) Her ba metabolism was 89 per cent., 91·3 per cent., 93·6 cent. on three occasions whilst asleep in the respirat chamber of the Joint Board of Research. (12) Mer torpor and apathy were a distinct clinical featu (13) Menstruation ceased nine weeks before admiss and returned 15 months later when she was recoveri (14) The improvement after injection of pituitary; has given excellent results in the published cases.

My thanks are due to Dr. T. C. Graves for permis to publish this case.

EXPULSION OF AN ECTOPIC FŒT PAPYRACEUS

AFTER UTERINE CURETTAGE

BY KENNETH MCFADYEAN, M.R.C.S. ENG.

THE following case of ectopic papyraceus fœ occurred in my practice last year; it is an exam of a very rare condition.

A multipara, aged 34, with three children, the youn of whom is aged 4, appeared to menstruate normally Sept. 24th, 1929. On Dec. 15th, 82 days later, she severe uterine hæmorrhage accompanied by sickness, sl fever, and acute abdominal pain on the left side. A pr tioner who examined her expressed the opinion that she pregnant, that the pregnancy had not been interfered w and that it would probably pursue its normal cou During the first week of January, 1930, there was fur very slight hæmorrhage. On Jan. 14th a bi-manual ex nation was made, and the uterus was found to be about size of a three months' pregnancy. At this time the pat stated that she no longer felt pregnant. A week later t was further slight hæmorrhage. On Jan. 27th there w small quantity of brown discharge. Examination reve no alteration in the size of the uterus. Surgical interfer was advised.

On Feb. 1st dilatation and curettage was perfor a tent having been introduced the previous evening. sound was first passed and appeared to enter an en uterine cavity 3 inches in length. After dilatation a fi was introduced, and the cavity carefully examined. patient was thin, with a lax abdominal wall, so that manual examination was easy. There was an indefi mass to the left of the uterus, the latter being distin globular in shape and freely movable. Nothing was in the pouch of Douglas or in the uterine cavity exc in the latter, a very soft, easily separated lining which thicker in the upper part on the left side. The entire of the uterus was freely scraped with a blunt cure hæmorrhage was severe and could not be checked by douching. The cavity was packed. Subsequently patient was given injections of half a cubic centimetr pituitary extract six-hourly. Microscopically the scra showed a decidual reaction.

On Feb. 2nd, at 11 A.M., the temperature rose to 10 and the pulse-rate to 132, while the patient had a and severe abdominal pain on the left side. The ute packing was removed without hæmorrhage. Pain persi all day and night. On Feb. 3rd, at 10 A.M., the tempera was 102° F. and the pulse-rate 120; a fœtus was expe The umbilical cord was wound tightly three times r the neck, while the proximal end was attached to a reta placenta. At 6 P.M., after further severe pain in the

of the abdomen, the placenta was expelled. The temperature fell to 99° F. and the pulse-rate to 98. The placenta, with some retro-placental blood clot, formed a cylindrical dry mass just under 4 inches in length and inches in diameter at its widest part. The patient made uneventful recovery and has menstruated normally since. The fœtus was examined by Dr. Audrey Russell, of the Institute of Anatomy, University College, London, who has kindly furnished the following report: (1) Gross anatomy: Decomposition had proceeded to mummification. The neck, extremely thin, showed a circular furrow, caused by the umbilical cord. The general development was that of a three months' embryo. (2) Radiogram: The vertical column in the cervical region showed great disturbance, with suppression of some of the centres of ossification. The centres of ossification were present in all the metacarpals, the phalanges and terminal phalanges in the hand, and in the metatarsals and terminal phalanges in the feet, indicating an age of about 83 days. The ends of the long bones show a line of arrested growth, suggesting that the embryo had had a precarious existence for a week before death. (3) Umbilical cord: 14·5 cm. long, was under one-tenth of an inch wide and flattened. Much of Wharton's jelly had been absorbed. The placenta showed advanced post-mortem degeneration, while a large retro-placental blood clot had been partially organised.

The conclusion from these data is that the pregnancy was isthmial, and that the fœtus died on Dec. 15th, being 82 days old, and was retained until the date of operation seven weeks later.

AN UNUSUAL ROUTE OF INFECTION IN CHOLECYSTITIS.

By R. Rutherford, F.R.C.S. Eng.,
SURGICAL REGISTRAR, KING'S COLLEGE HOSPITAL, LONDON.

Much has been written and much labour has been expended on discovering the various ways in which the gall-bladder may become infected. Undoubtedly in the vast majority of cases infection is carried by the blood stream. It may be useful, if merely to cite an exception to the general rule, to place on record the following interesting case.

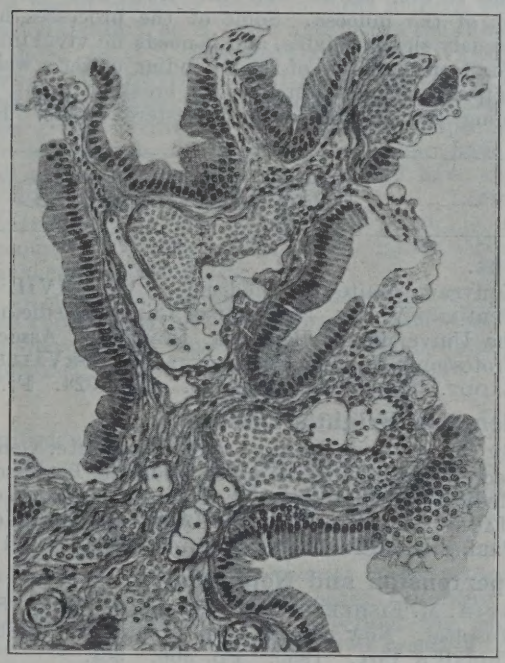
Fig. 1.

Gieson preparation showing excessive fibrosis in the gall-bladder wall in the vicinity of the adherent vermiform appendix. (× 35.)

The patient, a stout, unmarried female, aged 27 years, complained of pain in the gall-bladder region for some months. She also complained of indigestion, flatulence, constipation, and occasional pain in the right shoulder on. She had not suffered from vomiting or jaundice.

On physical examination tenderness under the right costal margin was elicited, but no tumour could be felt. A cholecystogram was done, and the gall-bladder was found to fill with the dye, and the radiogram, after a fatty meal, showed normal emptying of the viscus. The temperature and pulse-rate were normal. No stones were seen. A diagnosis of cholecystitis was made.

Fig. 2.



One of the papillary processes of the mucous membrane, highly magnified (× 190), taken from the vicinity of the adherent appendix. Note the vascular engorgement, the pavementing, and the commencing diapedesis.

An operation was performed, and the gall-bladder was seen to have lost its normal bluey appearance, and to be the seat of inflammation. In apposition with the gall-bladder were the cæcum and an inflamed appendix. Cholecystectomy and appendicectomy were performed, and the patient made an excellent recovery.

About the ninth week of intra-uterine life, the mid- and hind-gut assume their cœlomic position by retreating at the site of the future umbilicus, the hind-gut being the last portion to return. The cæcum comes to rest just below the liver, and rotation takes place. The transverse colon and descending colon come into being as anatomical entities, and the cæcum undergoes a relative displacement to its final resting place in the right iliac fossa; thus an ascending colon is formed.

In the case just cited the early fœtal position of the cæcum had been maintained, but the cæcum and the appendix were of the normal adult type. An ascending colon consequently did not exist.

The mode of infection was not apparent until sections were made of the whole gall-bladder wall. It was then observed that the serous and muscular coats had borne the brunt of the infection, and that the mucosa had almost entirely escaped. The section stained by the van Gieson method (Fig. 1) showed that fibrous tissue had been laid down in the muscle coat, and there was a dense fibrosis outside it. The blood-vessels were engorged; pavementing in their lumen and diapedesis had commenced (Fig. 2). A few polymorphonuclear and plasma cells were seen, particularly round the vessels. The mural vascularity was most marked in one segment of the section; it

was also at that point that the inflammatory cells were most in evidence, and relatively higher vascularity was also marked beneath the mucosa. This segment was regarded as the part of the viscus which was most nearly in apposition to the inflamed appendix (Figs. 1 and 2).

The section shows well the frond-like arrangement of the mucosa. Some of the processes have extremely slender stalks, and it needs no vivid imagination to picture one of them bending under a weight of imprisoned cholesterol to the breaking point, and forming the nucleus of a cholesterol stone. Here is an example of a case in which slight inflammati may just disable the gall-bladder and render it un for the normal cholesterol metabolism.

The appendix in section was seen to be the seat o chronic inflammatory process, as evidenced by t fibrous thickening of its walls, the vessels bei injected and the lymphatics infiltrated with infla matory cells, showing the superposition of a rece inflammation.

I am indebted to Mr. C. P. G. Wakeley for permission publish this case, and for the use of the excellent microsco slides and drawings.

REVIEWS AND NOTICES OF BOOKS

Reins.

Nouveau Traité de Médecine. Vol. XVII. By FERNAND WIDAL, Professor of Clinical Medicine in the University of Paris; A. LEMIERRE, Associate Professor in the same University; PASTEUR VALLERY-RADOT. Paris: Masson et Cie. Pp. 1024. Fr. 125.

Œdema of Bright's Disease.

By CH. ACHARD, Member of the Institute, General Secretary of the Academy of Medicine, Professor of Medicine in the University of Paris. Translated by MAURICE MARCUS, M.B., B.S.Lond. London: Kegan Paul, Trench, Trübner & Co., Ltd. 1930. Pp. 231. 9s.

Hypertension and Nephritis.

By A. M. FISHBERG, M.D., Physician, Mount Sinai Hospital, New York City. London: Baillière, Tindall & Cox. 1930. Pp. 566. 30s.

IT is a matter of common knowledge amongst students and medical men that as a rule books on nephritis do not serve to diminish the confusion prevalent on this difficult subject. It is therefore gratifying that in one season three books of outstanding merit should appear, any one of which is calculated greatly to increase the knowledge of any careful reader.

The 17th volume of Masson's System of Medicine deals with renal disease. It was about to appear when the medical profession in France suffered the loss of its principal author, the late Prof. Fernand Widal, who was also one of the general editors of the whole System. The work contains in its thousand pages the fruits of the lifetime of observation and research which this great physician had devoted to medicine, particularly to the diseases of the kidney. When he died, it was curious that his contributions to general bacteriology received most praise abroad, at any rate in this country; in France his name is renowned mainly for the magnificent work which he devoted to renal disease. A captious reader may find in this massive volume too much special pleading; the authors have indeed stated the case in favour of salt retention in nephritis with a force which many modern pathologists and physicians might consider exaggerated, but at a time when the views of Widal on this subject are being critically re-examined it is satisfactory to have those views expressed in clear and complete terms. The volume is valuable, moreover, for its lucid exposition of many of those first principles of biochemistry and of the essentials of morbid anatomy, without which no one can properly undertake a study of renal disease. The subject matter is arranged logically, and the illustrations, some of which are in colour, are adequate. The book is not confined to nephritis, but contains sections dealing with tuberculosis and syphilis of the kidney, renal calculus, malignant and parasitic diseases of the kidney, and the vario abnormalities of the urine commonly encountered medicine.

Prof. Achard is well known in this country for critical work on œdema and the work now publish in English by the Anglo-French Library of Medi and Biological Science is a notable addition to t literature. Prof. Achard writes clearly and has breadth of outlook which makes his views on œde in Bright's disease of great educational value. T discussion of salt retention on page 135 could scarc be bettered, and the section dealing with the collo of the blood and the theories of oncotic pressure admirable. The book will not, perhaps, make a w appeal but no one who is endeavouring to master complex problem of œdema can afford to ignore and no one who appreciates the difficulties of subject can fail to admire the skill with which author has displayed the facts. The translat throughout is well done; we have detected only bad slip, where (p. 219) the sodium ion is refer to by the word "Nation."

Lastly, an adequate survey of the whole subj of nephritis is contained in Dr. Fishberg's book. T American author is best known in England by work on blood pressure; he deals here with an e more complicated aspect of medicine. The chapter to the work is XI., where the classificatio Bright's disease is fully considered. Starting wit historical survey of the position before and during epoch of Richard Bright, Dr. Fishberg discusses classification, still prevalent in certain text-books renal disease, into parenchymatous and intersti varieties. After quoting the views of Wilks and Gull and Sutton, and of their successors in Germa he points out that this classification is now indef sible and should no longer be taught to students. proceeds to discuss the functional classificatio Bright's disease into supposed nitrogen-retaining chloride-retaining types, and again is able to dem strate the irrational nature of such a division. Fin he adopts as a classification acceptable in the pres state of our knowledge one which is essenti similar to that of Volhard and Fahr, which pla true inflammatory nephritis midway between degenerative nephroses at one end and the ischæ affections of the kidney at the other. The book whole supplies a clinical, experimental and pat logical demonstration which justifies this classificat The views here expressed are those of a small instructed body of physicians, representatives whom are to be found throughout the world. Wh indeed, the accumulated wisdom which is to found in the three books now under review filters the text-books, medicine will have made a g advance.

A System of Bacteriology in Relation to Medicine.

By Various Authors. Vol. V. Pp. 420. London: H.M. Stationery Office. In 9 volumes. £8 8s. or £1 1s. per volume.

THE fifth volume of the System of Bacteriology published by the Medical Research Council comprises sections on the pfeifferella (*B. mallei* and *B. whitmori*), the corynebacteria (*B. diphtheriæ* and the diphtheroids), the acid-fast group (*B. tuberculosis*, Johne's bacillus, the leprosy bacillus and the non-pathogenic acid-fasts), the brucella (*B. melitensis*, *B. paramelitensis*, and *Br. abortus*), anthrax, the non-pathogenic spore-bearing bacilli, *B. tularense* and bartonella and allied organisms.

The volume reaches the same high standard as its predecessors. Of the earlier portions of the book special mention may be made of the sections by Prof. R. Tanner Hewlett on *Corynebacterium diphtheriæ* and the diphtheroid organisms, particularly the portions dealing with laboratory diagnosis in diphtheria, and the section on the modern work with the Schick test. We wish that everybody concerned with the diagnosis of diphtheria would read the section on the laboratory diagnosis. There is hardly any branch of bacteriology where so much slipshod rule-of-thumb work is done as in the diagnosis of diphtheria, and the whole section, from the collection of material to the virulence test at the end, is a practical common-sense presentation of the subject. Prof. Hewlett writes with moderation on the relationship of the avirulent to the virulent diphtheria bacillus, about which there is much conflicting evidence. The section closes with a long description of the diphtheroids, including *C. hofmanni*, *C. xerosis*, *C. acnes*, and some of the lesser known diphtheroids producing disease in animals.

Nearly half the book is occupied with the acid-fast group of bacteria, of which 175 pages are devoted to the tubercle bacillus itself in all its bearings. In this section Dr. Stanley Griffith writes on the morphology and cultivation of the tubercle bacillus, experimental tuberculosis, and the distribution of the bacillus in man and in animals. This piece of work summarises the labour of many years. Dr. Griffith gives a fair summary of the vexed question of the filtrable form of the tubercle bacillus and discusses eugonic, dysgonic, and atypical strains of a bacillus—a subject on which his long research qualifies him to speak with authority. His chapter on tuberculosis in man includes an account of the portals of entry and a summary of work on the bovine bacillus in man. He also contributes a chapter on tuberculosis in cold-blooded animals, which contains much information not readily accessible elsewhere in English text-books. The section on allergy and immunity in tuberculosis by Dr. W. H. Tytler is very good. He gives a comprehensive well-reasoned survey, in the space of 50 pages, of a very difficult subject, and supplies a valuable bibliography. This section is indeed almost a complete monograph in itself. A short article on the preparation and standardisation of tuberculin by Dr. C. C. Okell brings together work on this complicated subject which has hitherto been scattered in journals and League of Nations reports. It is regrettable that more space was not allotted to the laboratory diagnosis of tuberculosis. For example, to dismiss in less than four lines the difficult task of finding the tubercle bacillus in pleural fluids is not helpful. The provision of a short chapter on the chemistry of the tubercle bacillus and other acid-fast bacteria, covering the ground of the first four chapters of Wells, De Witt, and Long's book on this subject, would have been valuable. In the section on chemotherapy in tuberculosis Prof. S. Lyle Cummins gives an excellent account of sanocrysin, and his last two paragraphs at the end sum up its possibilities with impartiality.

The article on leprosy by Dr. Ernest Muir, of Calcutta, is a useful summary which includes modern work on the cultivation of *B. lepræ* and brings the subject up to date. Dr. J. T. Duncan, Dr. L. E. H. Whitby, and Dr. A. D. McEven deal with the brucella group of organisms. Much new work has been published on this group during the last few years, especially on *Br. abortus* infection in cattle, the authors have made full use of the available material and have supplied a good bibliography. Prof. J. C. G. Ledingham contributes a chapter on tularæmia which includes an account of *B. tularense*, one of the latest arrivals in pathogenic bacteriology.

To every section of the volume Prof. W. Bulloch has contributed pithy historical introductions which supplement the long historical essay by him which appeared in the first volume of the System.

Injuries to Joints.

Third edition. By Sir ROBERT JONES, Bart., K.B.E., C.B. London: Humphrey Milford, Oxford University Press. 1930. Pp. 192. 6s.

THIS little book first appeared during the war and achieved an immediate popularity amongst those who were called upon to handle battle casualties. But, unlike most primers of that period, the book has continued to make appeal in civil practice. In the third edition nearly all war references have been deleted, and the principles of treatment are applied to everyday practice. Apart from these changes the only important addition is a few pages on Volkmann's ischæmic contracture, a subject much discussed at medical meetings and in the scientific press in recent years. The author has wisely preserved the character and size of the book and has not increased the number of pages. It is a handy pocket size and is not overburdened with detail; it can be read in a few hours and provides a useful and authoritative guide in the treatment of joint injuries.

Physiological Principles of Hydrology.

By R. G. GORDON, M.D., D.Sc., F.R.C.P.E., Physician to the Royal Mineral Water Hospital, Bath, and to the Bath, Somerset and Wilts Orthopædic Hospital; and F. G. THOMSON, M.A., M.D., F.R.C.P., Physician to the Royal United Hospital, Bath. London: Jonathan Cape. 1930. Pp. 131. 5s.

THIS is a short and readable book by two practising spa physicians. The authors have set out to write something which may help the practitioner to decide himself whether hydrotherapy will be likely to benefit his patients. Chemical formulæ have been avoided and an attempt has been made to give a physiological explanation of the action of waters. They hope that the reader may realise that hydrotherapy has its own special place in treatment, that the action of waters depends more on their physical than on their chemical properties, and that a cure depends on the power of the remedy to alleviate the underlying cause of the disease.

The first chapter contains an excellent short historic account of hydrology from Hippocrates up to the present day. Then follow four chapters on

physiology in its relation to medical hydrology. On the whole this is the least satisfactory part of the book. It would certainly be much improved if the references were supplied at the end of each chapter, so that the reader might know the authority on which the various statements are based. A few mistakes occur. Thus on page 32 thyroid deficiency is stated to be accompanied by a decrease in the respiratory quotient when the authors evidently mean the respiratory exchange. Again, they state that any method that will remove carbon dioxide from the body will increase oxidation and so prevent the formation and decrease the existing amount of fat in the body. The easiest way to remove carbon dioxide is to perform forced respiration; but there is no marked increased oxidation under these circumstances, only an alkalosis. On page 54 it is stated that in a hot immersion bath breathing becomes deeper and more rapid with a corresponding increase from 50–100 per cent. in the intake of oxygen and the elimination of CO_2. These statements rather suggest that the increased metabolism follows on the increased pulmonary ventilation, whereas it is almost certain that the opposite is true. Over 20 years ago Sutton showed that a rise of body temperature was accompanied by an increase in the respiratory exchange. However, the pulmonary ventilation is probably in excess of that required to eliminate the extra CO_2 produced and so there is an increased alkalinity of the blood and of the urine. This sequence of events is not expressed clearly in this book. The last chapters are certainly the most successful. In Chapter VI. there is a particularly valuable list of places in this country, in Europe, and also in Egypt where different types of waters are found Chapter VII. gives a good account of the various kinds of baths, while Chapter VIII. deals with the diseases which are commonly treated at hydrological stations.

Radiologie clinique du tube digestif: œsophage, intestin, foie et glandes annexes.

By J. GATELLIER, Professeur agrégé à la Faculté de Médecine de Paris, Chirurgien des Hôpitaux de Paris; F. MOUTIER, Chef de Laboratoire à la Faculté de Médecine de Paris; and P. PORCHER, Chef de Laboratoire de Radiologie à la Faculté de Médecine de Paris. Paris: Masson et Cie. 1930. Vol. I. Pp. 176. Vol. II. Pp. 389. Fr.330.

THESE two volumes are in continuation of a series of radiological atlases, other volumes of which we have already reviewed. Those hitherto published deal with the normal and pathological osseus system, the stomach and duodenum. The present volumes continue the alimentary tract and illustrate the normal and pathological œsophagus, the small and large intestines, and the accessory organs of digestion—the salivary glands, the liver, the gall-bladder, the pancreas, and the spleen. The system of explanatory line drawings adopted in the previous volumes of the series has again been used, and is a very helpful way of interpreting the radiograms. We have described this series as an atlas, but it is really more than this. In addition to the explanations of the radiograms, a considerable amount of text is included in each volume. All the conditions dealt with are well described, and an account of the pathology is given, besides full notes on the radioscopic and radiographic examination of the organs. The work is very complete, and every condition that it is possible to examine radiologically appears to have been included. The descriptions and illustrations of the large intestine are particularly well done. The volumes will be useful, both as books of reference and as an easy source of typical example of recognised radiological appearances.

Development of Sex in Vertebrates.

By F. W. ROGERS BRAMBELL. London: Sidgwic and Jackson. 1930. Pp. 261. With 24 plate and 25 text-figures. 12*s*.

Dr. Brambell's book deals with two subjects whic while distinct, are in many ways closely related (1) the phylogenetic evolution of the sex apparatu gonads, and sex cells; and (2) the determination sex in the individual. He weaves together classic morphology and experimental physiology into a ver clear account of a branch of knowledge which h made enormous advances in the last 10 or 15 year and the whole will be best appreciated if the la chapter is read first. The account of sex chrom somes and sex reversal is of particular interest, an the apparent contradiction between the chromosom theory and the facts of reversal seems to have bee satisfactorily settled.

Die seelischen Heilmethoden des Arztes.

By Dr. MAX LEVY-SUHL, Berlin-Wilmersdor Stuttgart: Ferdinand Enke. 1930. Pp. 28 M.15.

FROM these pages, written for the practitioner an concerned with the treatment of the neurotic, it ma readily be gathered that Dr. Levy-Suhl is not onl thoroughly conversant with different psychopath logical theories and psychotherapeutic methods, b applies with skill whichever he deems appropriate his clinical material. Illustrative instances a furnished of the most diverse types of case, som treated by simple suggestion, some by hypnosi some by analysis, some by combinations of techniqu Attractive little appendices are given at interval dealing briefly yet instructively with theoretic questions as they arise in the course of practice. T volume serves a useful purpose and can be recon mended for its eclecticism no less than for its breadt of view.

REPORTS AND ANALYSES

CONSTANTINO'S QUINA-PORT.

(PREPARED BY CONSTANTINO LTD., OPORTO.)
(SOLE AGENTS (WHOLESALE ONLY) J. AND G. OLDFIELD, LT 9, CHARLES-STREET, LONDON, S.W.)

THIS wine is described as "super tonic" an "rejuvenator," and is claimed to be made from pu old matured port, with which is incorporated quinin and other substances of a tonic character. Whe analysed the following results were obtained:—

	Per cent.
Alcohol by volume	19·5
equivalent to proof spirit	34·0
Fixed acidity, as tartaric acid	0·45
Volatile acidity, as acetic acid	0·03
Ash	0·27
Organic solids	13·88
containing glucose	11·50

and small amounts of quinine, &c.

The wine is of a natural port colour and free fro preservatives; the flavour is distinctly agreeable, and modified but very slightly by the presence of quinin

Such a product as this Quina-port merits the co sideration of the practitioner, as the tonic characte of the added medicaments and those natural to po wine are combined in an agreeable and palatable form

THE LANCET.

LONDON: SATURDAY, AUGUST 16, 1930.

DRAINS.

THERE is no conviction which dies harder in the public mind than that the control of communicable diseases is a problem of drainage. Hardly a day passes which does not bring to a big health department some urgent message about drains, with expressions of anxiety as to the prospects of an epidemic. Recently a circular issued by a medical officer of health, in which it was pointed out that drains had nothing to do with diphtheria, was the subject of indignant protests by plumbers, both locally and in the *Plumber*. It is easy to see how this has come about. In the second quarter of the nineteenth century the problem of public health was to the public mind the eradication of cholera, and the Royal Commission on the Health of Towns and Populous Places and the work of CHADWICK and his co-labourers demonstrated forcibly the association between epidemic occurrences and the insanitary conditions of the places where people had congregated as the result of the industrial revolution. It became evident that the primitive water-supplies on which the people still depended were grossly polluted as the result of the equally primitive means of disposing of excrement; and there can be very little doubt that the disappearance of cholera and the almost complete abolition of the alimentary infections in modern communities is the result of the attention devoted since these days to sewage disposal and communal water-supplies.

It is not so clear why the faith thus engendered in the beneficent influence of good drainage should have extended to those communicable diseases which do not as a rule gain access to the human body by the alimentary route. Presumably it was due to an association of ideas and imperfect understanding of the modes of transmission of these diseases. It is mostly in relation to diphtheria or sore-throats in general that the public are still concerned about defects of drainage, and it must be admitted that the pronouncements of the medical profession and sanitarians have been largely responsible for this point of view. STEVENSON and MURPHY, in their book written in 1892, said: "The spread of diphtheria has been ascribed to the pollution of air by emanations from sewers, and certainly there is a close connexion between the sanitary condition of a district and the occurrence of this disease; the inhabitants of houses into which sewer gas enters are especial sufferers," and this was expressive of the belief generally held at that time by those who were responsible for the care of the public health. The nature of the infection and the conditions precedent to its propagation were not yet fully understood. The diphtheria bacillus had been described by LÖFFLER in 1884, its toxin separated by ROUX in 1888, the antitoxin produced by BEHRING and KITASATO in 1890 and 1893, and a commencement made with the treatment of diphtheria with antitoxin in Paris and Berlin in 1894. LÖFFLER himself had hinted at the presence of the bacillus in apparently healthy throats, and PARK, as the result of his investigations in New York, in 1893, suggested that probably 1 per cent. of the healthy throats in that city were infected. Since these discoveries were made there has been a gradual growth of knowledge on the transmission of infection, and we have come to realise that, at least so far as the air-borne infections are concerned, their epidemicity is a problem of mild infections and carrier states rather than of sanitary circumstances which can be controlled by any engineering works. We find, then, in modern text-books statements such as these: "When sewer air leaks through a defective fitting into the air of a house its noxious influence, if any, is further attenuated. There is no evidence that under such conditions it either causes specific disease or predisposes to it" (CURRIE). A slightly more cautious note is struck by JAMESON and PARKINSON, who say: "The continued inhalation of drain and sewer air has been thought to predispose to a general loss of health, e.g., anæmia, headache, vomiting, sore-throat, skin eruptions, and diarrhœa. Possibly only a reduced vitality is produced, which renders the individual more susceptible to bacterial infection." In the second edition of PARK'S "Public Health and Hygiene," published in Philadelphia in 1928, no mention whatever is made of drainage in the part devoted to diphtheria, and the only statement bearing on the subject is under the heading "General Municipal Sanitation," where, in relation to bad plumbing, it is said that "these conditions result in pipes and fixtures which leak and are a menace to health," which reads rather as a vague concession to former teaching than as a convincing pronouncement of modern views. ROSENAU (1927) says bluntly: "Formerly, imperfect drains and sewer gas were given as the cause of diphtheria; this is a fetish which dies hard." Finally, those who read Dr. HASLAM'S book on "Recent Advances in Preventive Medicine [1]" will find the following introductory comment which leaves no doubt about the change of outlook on the care of the public health. He says:—

> "Text-books and teachers have long combined to convey the impression that preventive medicine was the special province of those more interested in drains and damp-proof courses than in human ills, though the long held belief in the close connexion between drains and the infective fevers permitted the preventive doctor to concern himself with the latter. Nowadays it is hardly going too far to say that all medicine is preventive medicine."

Until recently most public health departments made the occurrence of communicable disease in a house an excuse for examining the drains, and no doubt this practice persists in many towns.

[1] J. and A. Churchill. 1930. Pp. 328. 12*s*. 6*d*.

The reason for its continuance is due to the fact that the law permits of drain-testing only if the responsible officers can establish reasonable grounds for suspecting that the drains are defective. In the absence of a case of fever it is rarely possible to find such evidence, yet in practice it has been found that the routine tests made at infected houses do discover very many defects of drainage, and their discontinuance would undoubtedly lead to a deterioration in the condition of house-drains. On general principles it is undesirable that anything which is offensive or objectionable or nauseating should be allowed to continue, and it is not surprising, therefore, that the health departments are reluctant to forego any opportunity of making these examinations. Until there is some amendment of the law, however, it is essential that the misleading educational influence of this practice should be counteracted by constant instruction of the public as to the truth concerning the transmission of disease. Practitioners of medicine are sometimes guilty of expressing obsolete views on this topic. Their great influence carries with it a responsibility for helping to guide the public away from the erroneous conceptions of infection which are so commonly held.

GALL-BLADDER DISEASE.

INQUIRY goes on into the causation of gall-stones and of inflammation of the gall-bladder. Clinical study and laboratory technique, especially Graham's cholecystography, have thrown light on the diagnosis and symptomatology of these conditions, but until we have a clearer understanding of their ætiology we can do little to prevent their occurrence. All are agreed that a large proportion of gall-stones have their primary origin in an infection of the biliary tract, although a certain number may be metabolic in origin, the best example of these being the pigment calculi found in acholuric family jaundice. In most cases, however, the two conditions—stone and inflammation of the lining membrane—are found together, leaving room for discussion as to which of the two occurred first. Mr. A. J. WALTON,[1] in a recent review in our columns, was strongly of opinion that the initial change is most frequently an inflammation which gives rise later to calculus formation. Even with a pure cholesterol stone, which has been generally regarded as metabolic in origin, WALTON found inflammatory changes in the gall-bladder in every one of his own 23 cases. What, then, are the factors which lead to infection of the gall-bladder and biliary passages? Clearly infection may reach the bladder (1) through the common bile-duct and the cystic ducts from the duodenum; (2) via the portal vein; (3) through the systemic circulation; or (4) by direct or lymphatic spread from the liver. As a result of his closely reasoned survey, WALTON leaned towards a blood-borne infection, at first a part of a general infection or mild septicæmia.

There are many clinical features to support this view, which is also in harmony with the experimental work of ROSENOW, WILKIE, and others, who have cultivated streptococci from the wall of the gall-bladder in a large proportion of cases examined in which the bile itself was sterile. ROSENOW has indicated the selective action of certain streptococci towards particular viscera, and such affinity would explain the localisation in the gall-bladder of organisms which have reached it by way of the systemic circulation. An important investigation by the Edinburgh school appears in our present issue. Dr. BRYAN WILLIAMS and Dr. D. G. S. McLACHLAN have examined the bacterial flora of 106 gall-bladders removed from the living body on account of disease. In 84 cases of chronic cholecystitis in which the gall-bladder wall was examined under strictly controlled conditions, a streptococcus was found in 17 per cent. and the colon bacillus in 23 per cent. In the great majority of those cases in which a streptococcus was found whether in the gall-bladder wall or in the cystic lymph gland, it was also present in the bile; only once was a streptococcus isolated from the bile in the absence of stone. Injection into rabbits of organisms derived from such infected human material was followed in only a small proportion of cases by a definite cholecystitis; thus, only one rabbit injected intravenously with streptococci and one injected with colon bacilli developed gross lesions in the gall-bladder. Hæmorrhages into the stomach were frequently found in these animals—an observation of some possible significance in relation to gastric ulceration in the human subject although a number of other substances may lead to similar changes.

The majority of the streptococci isolated by WILLIAMS and McLACHLAN were of the entero coccus type, suggesting derivation from the bowel. They do not conclude that any of the organisms isolated are necessarily the primary agents of gall-bladder inflammation; they may merely be secondary invaders. Their work, however, does not confirm the view that organisms usually reach the gall-bladder by means of the systemic circulation, nor does it support ROSENOW'S theory of elective localisation. Direct or lymphatic spread of infection via the liver may be of as great or greater importance. Prof. E. A. GRAHAM[2] has shown that some degree of hepatitis is an almost constant accompaniment of cholecystitis; it is also frequently found in such conditions as chronic appendicitis though rarely of such extent as when associated with disease of the biliary tract. It would seem, then, that chronic infective processes in the area draining into the portal system may lead to a hepatitis which, in its turn, permits organisms which would normally be filtered off by the liver to pass into the gall-bladder, or give rise to a direct spread of infection from liver to gall-bladder wall. Mr. E. R. FLINT has recently directed attention afresh[3] to the frequent association of hepatitis with cholecystitis and with other intra-abdominal lesions, and an unusual case is discussed by

[1] THE LANCET, 1930, i., 334.

[2] Surg., Gynecol., and Obstet., 1918, xxvi., 521.

[3] Brit. Med. Jour., 1930, i., 1041.

Mr. R. RUTHERFORD in our present issue in which direct spread of infection from an abnormally situated appendix led to infection of the gall-bladder wall and cholecystitis. It would clearly be unwise to accept a blood-borne infection as the sole cause of cholecystitis to the exclusion of a lymphatic or direct origin.

MEDICAL RESEARCH IN INDIA.

IT is a relief to turn from the troubled waters of the Indian lay press to the quiet current of scientific work in India, which goes on undisturbed. The report for 1929 [1] of the Calcutta School of Tropical Medicine, with the associated Hospital and Institute of Hygiene, shows that here, at all events, Europeans and Indians are working harmoniously for the good of humanity, and the most impassioned patriot cannot but admit that his countrymen are getting a fair chance. Of the nine professors and lecturers in the various departments five are Indians, while the posts of assistant professors, where they exist, are all held by medical men native to the country. The Director is known to search for indigenous scientific merit, and to welcome any sign of it most cordially. Colonel J. W. D. MEGAW, late head of the school, has been appointed Director-General of the Indian Medical Service, and has been succeeded by Lieut.-Colonel H. W. ACTON, who makes of his first report an opportunity not merely to describe the year's work, but to survey over a longer period the advances in tropical medicine with which the school has been specially concerned. It is an impressive record, involving important contributions to our knowledge of some of the worst scourges of warm climates.

Colonel ACTON remarks that the name of LEONARD ROGERS, who founded the school, is associated with revolutionary changes in the treatment of four of these scourges—amœbic dysentery, cholera, kala-azar, and leprosy, and it is not significant that he made use of drugs which had previously been employed. Amœbic dysentery had been treated for many years by ipecacuanha, but it was left to ROGERS to show that emetine, which later observers had prided themselves in removing from the crude drug, was really the important factor, and to demonstrate that it could be administered hypodermically with advantage. Similarly, saline injections had been given for cholera, but a laborious investigation was needed before the superiority of the hypertonic solutions was admitted. Treatment with the hydnocarpus compounds, introduced again by ROGERS, has changed the whole outlook in leprosy, and lastly, his employment of intravenous injections of sodium antimony tartrate for kala-azar led the way to the reduction in the mortality-rate of that disease which is perhaps the most striking recent result of the activities of the school. This pioneer work is most generously recognised in the report. It has to be remembered, also, that much remained to be done, and for that, and for developing the work in the directions indicated by ROGERS for a large amount of original work on other aspects of tropical medicine, Colonel ACTON and his collaborators deserve credit. One of the interesting recent activities mentioned in the report is the research on bacteriophage, initiated at the visit of Dr. D'HERELLE in 1927. Dr. D'HERELLE worked in the school for several months, and evidently imparted a full share of his enthusiasm to his colleagues there. The whole question of the use of bacteriophage is still sub judice, but Colonel ACTON is evidently impressed with their possibilities, not only as regards treatment, but also in throwing light on the bacteriology and epidemiology of cholera and dysentery. Experimental work on bacteriophage is proceeding in the laboratory and in the field. The campaign against kala-azar has now reached a satisfactory stage as far as a diagnosis and treatment are concerned. The new finger prick test with urea stibamine enables the disease to be identified almost with certainty in a few minutes, and the improved course of treatment by injection with pentavalent compounds of antimony (lasting only 5 days, as contrasted with the previous 60 to 90 days) is said to cure permanently 95 per cent. of the cases, with only 5 per cent. of relapses. There are now very few deaths in hospital from this disease, which used to be considered almost universally fatal. Work on the transmission of kala-azar is also progressing well. There is no longer any doubt that *Phlebotomus argentipes* is responsible, though the exact mode of transmission has not yet been demonstrated. Feeding experiments with these sand-flies have so far failed to produce the disease, and it is suggested that the oral route is the most likely method of human infection. Sand-flies are easily killed in the act of biting, and it is thought that the fingers may get contaminated, and the parasites be introduced to the mouth in this way. A curious point has emerged during an investigation in Calcutta. Kala-azar is not endemic in the northern portion of the city, since the sand-flies live and breed in the cowsheds, and feed on cattle; whereas in the south, where they live in fowl runs, they feed on human beings, and hence the disease is endemic.

An important feature of the school is the leprosy department. During the last year attention has been specially paid to improving the general resistance of sufferers by the administration of various remedies, of which potassium antimony tartrate, given intravenously, and sodium bicarbonate, by the mouth, have been found useful; thyroid, when used with care, is said to have proved of great value. An indigenous drug, *Holorrhena dysenterica*, which has recently been found useful in chronic dysentery, investigated both in Bombay and Calcutta, has been employed with advantage, both as a general tonic and as a treatment for dysentery—a condition often accompanying and predisposing to leprosy in Bengal. The intradermal injection of esters by multiple puncture has been found to speed up the resolution of lesions. Research is also proceeding in many

[1] Calcutta: Bengal Government Press. 1930. Pp. 116.

other directions, of which hookworm, malaria, and skin diseases are examples. The last section is in charge of the Director himself, and the clinical and laboratory work carried out has already borne much fruit. The Institute of Hygiene is now, thanks to the generosity of the Rockefelle Foundation, being developed into an All-Indi Institute, with special buildings, and its develop ment is likely to have a great and beneficial influ ence upon the study and practice of hygiene in India

ANNOTATIONS

INTERNATIONAL CONGRESS OF DERMATOLOGY AND SYPHILIS.

WHEN the Seventh International Congress of Dermatology and Syphilis met in Rome in 1912 it was decided that the next meeting should take place in Copenhagen, but it was not then anticipated that 18 years would elapse before there would be another opportunity for international rapprochement and discussion. The formal inauguration of the Eighth Congress, which was held last week from August 5th–9th, took place in the "Folketinsaalen" of the Royal Palace of Christiansborg, in the presence of King Christian, with his Prime Minister and the Mayor of Copenhagen. In his opening address Prof. C. Rasch, the Danish president of the Congress, welcomed his 965 guests, and deplored the absence of famous men, notably Neisser, Unna, Brocq, Hallopeau, and Fordyce, who had attended the last Congress but had since died. Forty-two countries were represented, and the task of the general secretary, Dr. Svend Lomholt, must have been heavy. His organisation, and the coöperation of the municipal authorities for the reception, accommodation, and entertainment of the members and associates, have been beyond praise, particularly when it is remembered that Copenhagen is a town of only 300,000 inhabitants. The programme included a visit to the Rigshospitelet of 1800 beds, where rare dermatological and venereal cases were inspected and discussed on the third day of the congress. Time was also found for a demonstration by Finsen's successor, Prof. A. Reyn, of modern methods and apparatus for the actinic treatment of lupus and allied affections of the skin. The scientific discussions were allotted to three main themes for general discussion: the Ætiology and Pathogenesis of Eczema; Immunity, Reinfection, and Superinfection in Syphilis; and Cutaneous Tuberculosis and its Treatment. Introductory papers by Darier and Jadassohn on eczema were followed by communications from Bruno Bloch, Oppenheim, Pusey, Sabouraud, and Whitfield, and ushered in a general discussion in three languages (French, German, and English), which will long be remembered by those privileged to listen and able to comprehend. Syphilis was reserved for the next day and took place in another room of the palace, simultaneously with the beginning of a series of 177 personal communications from dermatologists and syphilologists from all parts of the world. Many of these were illustrated by diagrams. clinical photographs, charts, and curves, and had to be delivered at a speed which troubled members not fully conversant with the particular language used, and hampered discussion. Much work of undoubted value escaped due notice and this suggests that the time has come for a reconsideration of the programme of nearly all medical congresses, especially international ones. There appears to be no control, beyond the time allotted to delivery—and this is often extended out of courtesy to individuals—of the suitability and quality of papers submitted for discussion. While most of these are doubtless of value, many are not up to international standard, or could have bee further pruned with advantage. A tribunal set u in advance by the delegates would find no difficulty although it might incur some odium, in dividing th communications submitted to almost any congres into three categories: (1) those accepted for discussion (2) those accepted for publication in the printe proceedings; (3) those rejected: (*a*) for reason of inadequacy; (*b*) for revision, curtailment, an subsequent publication. This Congress suffered les from unsuitable communications than many other but even here some process of preliminary selectio would have served to make the week even mo profitable to dermatologists of all countries.

ON GIVING ADVICE TO THE TUBERCULOUS

THERE is often an air of infallibility about th giver of advice. He is so certain he knows and s sure also that the recipient does not. Small wonde therefore, if the modest physician hesitates to d more than answer specific questions from individu patients. But since, as Dr. F. M. Pottenger remarks "intelligence is the most potent factor that ca be directed against disease," no doctor can in practi refrain from giving general advice, especially in disease involving habits of life, like tuberculosi Three recently published books on this subject, a of them in their own way excellent, show i what different ways the task may be approache Dr. Pottenger's book, now in its second editio attacks the subject from a physiological basis an goes into fuller detail than most other writers for th layman. "No question," he says, "asked by a earnest patient is too insignificant for an answe and no fact that will aid him in recovering healt should be withheld from him." Starting out from th point of view, sections on the CO_2 content of the ai the principles of metabolism, the mechanism of pr duction of cough, temperature regulation, and lik questions are the natural outcome of a conscientio desire to tell the patient every relevant fact. Th method is obviously only applicable to the mo intelligent patients in private practice and sanatorium and cannot be applied to the hospital class. Moreove it is a method requiring much foresight and intuitio if the patient is not to become neurotic. But, give the suitable patient and the wise physician, it a course satisfactory to all parties. Dr. Pottenge book is an admirable corrective also to that ligh hearted class of physician who thinks his duty end when he has advised his tuberculous patient to tak a sea voyage or to go and live in the country an take up poultry farming. "I would rather be treate intelligently in the worst climate than be allowe to run wild in the best," is a dictum of Dr. Pottenge which not only patients but physicians shou ponder. Dr. F. J. C. Blackmore,[2] tuberculos

[1] Tuberculosis and How to Combat It. A Book for t Patient. Second edition. London: Henry Kimpt Pp. 275. 10*s.* 6*d.*

[2] The T.B. Patient's Guide. London: Cassell and 1930. Pp. 76. 1*s.* 6*d.*

officer for Woolwich, has devised a little pocket manual to meet the needs of the patient who attends the tuberculosis dispensary, especially in the London area. He gives advice on home treatment, the sanatorium, complications and their treatment, employment, and so forth. Dr. Blackmore stresses the point that failure is often due simply to lack of knowledge on the part of the patient. In this book little or no physiological theory is included, but many practical points. The patient is told what sanatoriums exist (especially in the London area), what rules he will be expected to comply with on admission, and what clothes he should take; how to disinfect his crockery and dispose of his sputum; what State and voluntary funds may help him (some useful information on National Health Insurance and approved societies is included), and what occupations are suitable for him when he reaches the stage of "cure." Different again is the aspect of tuberculosis discussed by Dr. Kurt Klase,[3] Director of the Prinzregent-Luitpold-kinderheilstätte of Scheidegg. His book, written in German, is designed solely to explain the meaning of tuberculosis in childhood to the lay public. Its most valuable content is the removal of the fear that tuberculosis in childhood is the appalling and fatal disease which the Victorian novel taught the public to believe. Dr. Klase points out in simple language that in childhood infection with the tubercle bacillus is the rule rather than the exception in modern civilised life, but that this infection is by no means a thing to be afraid of and is very different from the acute fatal tuberculosis which occurs in a small proportion of children. The book is a good example of the best kind of public health propaganda which imparts knowledge simply without sensational detail.

INTERNATIONAL LEAGUE AGAINST TRACHOMA.

THE International Anti-Trachoma League, the foundation of which was planned last year at the International Ophthalmological Congress held in Amsterdam, has now taken shape. A meeting took place last month in the Palace of the League of Nations in Geneva, 21 different States being represented by 40 delegates. Prof. Dr. Emil de Grósz presided, the statutes were passed, an executive committee was formed, and a preliminary programme for the campaign was outlined. The objects of the League are: to further the coöperation of the various organisations for the prevention of trachoma; to enlist the help of the international bodies concerned with public health; to keep in touch with all measures designed to combat the spread of trachoma and to further their adoption; to attempt to place the campaign on a scientific basis; to elucidate the ætiology as well as to extend the treatment of the disease; to investigate its social aspects, and finally to formulate legislative measures designed to prevent it. Prof. de Grósz was elected president of the League, to hold office for five years; Dr. Wibaut (Amsterdam), secretary-general; Dr. Tewfik (Cairo), secretary. The representatives of the Hygiene Committee of the League of Nations, Mr. Lutrario, former chief of the Italian Medical Department, and Mr. Jitta, chairman of the Dutch Board of Health, have prepared a report on trachoma which has been distributed by the Council of the League of Nations. Dr. Olitsky (New York) attended the meeting at Geneva on behalf of the Rockefeller Institute, and delivered an address on the importance of the bacillus discovered by the late Dr. Noguchi, and Mr. Addario (Palermo) and Mr. M. S. Mayou (London) gave demonstrations. The delegates from the different nations evidently welcomed the opportunity of discussing common and complementary problems, and everything points to the likelihood of the League becoming a prosperous and useful undertaking. The countries which are obliged by their geographical position to take steps to prevent the introduction of trachoma are in the same need of a campaign against it as those where it is actually destroying eyesight. In Hungary the campaign against the disease was started as long ago as 1886 by the passing of a special law. The exertions of Japan in this respect are also worthy of praise, for there exist in that country 1000 trachoma departments where half a million trachoma patients are treated annually by specialists at a cost of half a million yen a year. The League of Nations has issued a special circular letter to all Governments requesting them to support the scheme, and we trust that the response will be good.

MILK-BORNE EPIDEMICS.

THE epidemic of sore-throat which occurred in Brighton and Hove in November–December, 1929, and was traced to milk is the subject of comment by Dr. D. Forbes in his annual report, which we notice on p. 371. He gives two reasons why some time elapsed before milk was suspected in this outbreak. One is that while epidemics of scarlet fever and diphtheria due to milk are frequently reported, outbreaks of other forms of sore-throat have only occasionally been traced to milk in this country. Secondly, the practitioners thought that they had to do with a special type of influenza focusing itself upon the pharynx; such types of sore-throat are not notifiable. Dr. Forbes makes some suggestion which, if adopted, might prove helpful in detecting sore-throats due to milk. The first is to empower the medical officer of health to ascertain the source of the milk-supply promptly in cases of sore-throat which are not notifiable. In Brighton, for example, some 24 swabs from suspicious throats are received weekly, of which 21 give negative results for diphtheria bacilli. Dr. Forbes proposes, and the local division of the B.M.A. concurs, that every practitioner who sends a swab for examination should fill in on the accompanying slip the source of the milk-supply. The arrival of a number of slips quoting a particular milk-supply would arouse suspicion at an early stage of an outbreak. A second suggestion is made that the model form of contract between producers of milk and distributors should include a clause requiring the producers to notify to the distributor not only the legally notifiable diseases but also any type of sore-throat or diarrhœa occurring in the families of his employees. This suggestion has been approved by the Home Counties Branch of the National Federation of Dairymen's Associations. The Brighton Health Committee have asked the Ministry of Health to make regulations, if possible, rendering this form of notification by the milk producer compulsory. In the third place Dr. Forbes points out that, in his view, pasteurised milk is the only designated milk which gives protection to the consumers against such outbreaks. He adds that one-third of Brighton's milk-supply is now pasteurised, although only a portion of it is sold as designated milk.

Critics might say that if pasteurised milk is not sold as designated milk there is no control of the

[1] See THE LANCET, 1930, i., 94, 99, 213.

method adopted or of its adequacy; and also that since adequate pasteurisation can only protect against infection of the milk before the time of pasteurisation, the possibility of infection by the distributing agency has still to be reckoned with. Infection of the milk has often been traced to the distributing dairy as distinct from the producing dairy farm. It might be contended that dried milk is safer even than pasteurised from this point of view, but milk-borne epidemics are so rare that public opinion would hardly contemplate the abolition of liquid milk on this ground. If precautions such as notification of milk-supply were adopted the risk to the householder would be very small, and he could, if he wished, reduce it still further by adopting, as an alternative, an adequate form of home pasteurisation or the west country method of setting up the milk for clotted cream.

THE LEGALISATION OF EUGENIC STERILISATION.

THE promotion of legislation to permit the sterilisation of such persons as should be prevented, in the interests of the community, from reproducing their kind, is one of the objects of the Eugenics Society. The society appointed a special committee to further this object and the report of the committee is summarised in another part of this issue (p. 369). That legislation is necessary is hardly in doubt, for so eminent an authority on the common law as Mr. Justice Humphreys has stated that, no matter how admirable the motives of surgeon, parent or guardian, the surgeon who operated would certainly be indictable under the Offences against the Person Act, 1861, and the parent or guardian under the Mental Deficiency Act, 1913. Even voluntary sterilisation is stated by Lord Riddell probably to constitute a maim, an old term for a serious injury likely to interfere with fighting power; castration has always been considered a very serious maim, for it is believed to reduce the courage of the person on whom it is practised. The committee outline the provisions of the Bill which they intend to draft; the sterilisation which they propose to legalise would in all cases be voluntary, except that a defective of such a low grade as to be unable to give consent might be sterilised with the consent of his relatives on discharge from an institution. The Bill is to be divided into three clauses or parts, dealing respectively with mental defectives, the recovered insane, and persons suffering from grave transmissible diseases and defects other than insanity and mental defect, and—what many will consider a very advanced provision—those desiring to avoid procreation on eugenic grounds. The arguments of the advocates of sterilisation cannot be dismissed without careful consideration. As the report points out, it is no part of the proposals that the policy of segregation should be in the least relaxed. Although R. A. Fisher calculates that, if all primary aments were prevented forthwith from breeding, the incidence of mental deficiency would be reduced by 17 per cent. in a single generation, other authorities think that in practice sterilisation would not have much appreciable effect for a far longer period. An argument harder to counter is that it would do a certain definite amount of undeniable good without any harm that can be convincingly demonstrated. It is accepted as fact that defectives very often have defective children and that as a class they fail lamentably in managing their homes and bringing up their offspring. It is difficult to see how, in the absence of proved harm, the community could lose by their sterilisation; the tendency to neuropathic disorder is known to be transmissible, and it is not unreasonable to aim that as little should be transmitted as possible. The chief argument against the sterilisation of defectives so low in intelligence that they are unable to give consent is based on the desirability of safeguarding the natural rights of the individual, however little gifted. But it must be remembered that in some cases liberty of movement, which the community would otherwise insist on curtailing, could be exchanged for liberty of procreation. The case against sterilisation rests essentially less, perhaps, on the desire to protect the individual than upon a very old concept which concerns the welfare of the State—viz., that no one, even by his own consent, should be allowed to undergo an injury that would depreciate his value to the State as a fighting man, or as the procreator of fighting men. It is doubtful whether even castration—and that is not recommended by the advocates of eugenic sterilisation—abolishes courage; the Tawashia of the old Arab and Turkish civilisations were not only good soldiers but good leaders. Even if it be admitted that it is necessary for the State to safeguard the breeding of warriors, the classes whom the committee propose to allow to consent to their own sterilisation are not those from whom such stock can reasonably be expected. It is at least conjecturable that the real objection to sterilisation is rooted far more deeply, in the instinctive fear of mankind of death, either of the individual or of the race. The procreative instinct is the race's most potent weapon against death, and to fetter its freedom appears at first sight to be a dreadful thing. It can be argued, however, that there are few things more really dangerous either to the race or to the individual, than an unfettered instinct, and that indiscriminate multiplication in the community is no less deadly than cancer in the human body. The problem of the mentally unfit is a very urgent one, and the community can only steer the safe middle course by reasoned judgment based on proved fact.

THE HEALTH OF THE ADULT WORKER.

A FALLING mortality, especially in early years, is generally accepted as a sign of successful public health measures. But we may now and again pause to examine the results. A generation resulting from a low infant mortality is now reaching adult years. What connexion, if any, is there between this circumstance and the fact recently stated by the Secretary for War that something like 61 per cent. of those who offer themselves as army recruits have a reduced standard of height, chest measurement, and dental requirement?[1] We read, moreover,[2] that whereas the approximate number of weeks for which sickness and disablement benefits were paid under the National Health Insurance Acts in 1919 was 19 million weeks, it was 25 million weeks in 1925, and 29½ million weeks in 1929, even though since January, 1928, the age at which sickness and disablement benefit is paid was reduced from 70 to 65. In the registration area of the United States mortality in early life has been falling, as in this country, but now a new phenomenon has appeared over there—for all ages after 35 the mortality in 1927 had risen as compared with 1921. We seem, then, to be faced with a greater need

[1] THE LANCET, August 9th, p. 318.
[2] Ibid., p. 319.

than heretofore for safeguarding the adult years of life

The report of the Factory Department [3] gives an indication of the position among industrial workers, and of the efforts made to combat adverse influences on their health. In the section on the occurrence of accidents, which represent the reaction of the individual to his environment, we find that, as usual, 80 per cent. were due to causes such as falls, struck by falling body, handling goods, and use of hand tools; all of which are causes under personal control, more likely to be avoided by those whose special senses are acute and whose reactions are brisk. Only 20 per cent. were caused by moving machinery; and even here lack of personal acuity is often the determining factor. The number of reported accidents rose from 154,319 in 1928 to 161,269 in 1929; and fatalities from 953 in 1928 to 982 in 1929. Here, again, evidence seems to indicate that human adult material is less resistant than heretofore, and less capable of meeting the hazards of life. This rise in the occurrence of accidents is the more disappointing in that a steady campaign to spread safety-first methods is being pressed forward by the factory inspectorate. A further disquieting fact is that sepsis occurred in 10 per cent. of the reported cases; since some of these were strains and sprains which would not be associated with any wound, the proportion of wounds which went septic is even higher than this figure suggests. The reason may be neglect to make adequate use of first-aid appliances, but may also suggest lack of good capacity for healing. Examples are quoted to show how well-planned efforts may reduce accidents, in one case a frequency-rate from 85·6 in 1927 to 67·7 in 1929, and a severity-rate from 2·2 to 1·7. Education and organisation are indeed needed. One fatality was due to walking on an 18-inch steel girder at a height of 75 feet from the ground; the man was reading a plan and, not watching his steps, walked off the end of the girder. Many instances of carelessness are quoted, resulting in electrical accidents; but here, while the hazard, as measured by units of energy sold, has doubled during the six years ended 1928, the accidents have only increased by 8½ per cent.—a commendable result due to practical regulations controlling the methods of supply and the apparatus used. A warning is given that the alternating system, adopted by the Electricity Commissioners for general use, is more dangerous to life than the direct current system.

Much of medical interest is described by Dr. J. C. Bridge, whose report deals increasingly with wider aspects of health and disease, while comparatively less space is devoted to old-time favourites, like lead poisoning and anthrax. Cases of lead poisoning only numbered 169 for the 12 months compared with 242 in 1926, 505 in 1910, and 1059 in 1900. This result has followed suppression of dust containing lead salts; indeed as Dr. Bridge says, this is the "dust age" in industrial medicine. Silicosis, due to inhaling silica dust, is to-day the most prominent industrial disease, the full prevalence of which, as revealed by recently granted compensation, is not yet known. A new disease, due to the dust of asbestos, has been detected, causing diffuse pulmonary fibrosis, disablement, and death without a superadded tuberculous infection. Of almost equal importance are the cases of epitheliomatous ulceration of occupational origin, arising from contact with pitch, tar, paraffin, or mineral oil, all distillation products of coal; they showed a slight reduction on the previous year, 165 with 50 deaths, as compared with 175 with 59 deaths. Here the institution of periodic medical examination in the industries concerned is bringing the risk under control. A closely allied trouble is that of dermatitis, which shows no tendency to diminish, while painters claimed an increased proportion, 10·3 per cent. of the cases, due probably to the use of turpentine to clean their hands and arms. Chromic acid and chromium compounds, used in lithographic processes, were sources of skin irritation; as were cutting lubricants and cooling liquids used in engineering. The use of an alkaline wash, such as chlorinated soda, is recommended for removing oil and grease after work. Many other matters of interest are noted, including a satisfactory increase in the number of workers with knowledge of first-aid, and in the provision of ambulance rooms, as well as special reference to cases of gassing. Here carbon monoxide continues to claim more cases and deaths than all other gases taken together; generally the cases are tragic, and could have been prevented. One man, overcome at some simple job, jeopardises the lives of others who attempt rescue with courage, but without application of proper principles.

The report leaves the impression that the industrial worker, as well as industry, is in these days depressed.

[3] Annual Report of the Chief Inspector of Factories and Workshops for 1929. 1930. H.M. Stationery Office. Cmd. 3633. Pp. 173. 2s. 6d.

AN OFFICIAL CORRECTION FROM THE M.R.C.

WE have been desired by the Medical Research Council to publish the following official statement from the Council.

The attention of the Medical Research Council (Great Britain) has been drawn to a misleading advertisement, involving misuse of their name, which has been given currency on the American Continent in respect of a preparation of ergotamine tartrate known as Gynergen "Sandoz." This advertisement states that "The Pharmaceutical Society of Great Britain, after consultation with the Medical Research Council, adopted Gynergen as the standard for ergot, thus making it the acknowledged leader in this field." This statement is not true.

The Medical Research Council desire to make it plain that they never at any time concurred in, or were consulted about, the adoption of this preparation as a standard. The suggestion made with reference to the Council is therefore entirely without foundation, and any statement implying their approval is a gross misrepresentation.

Further, the current official publications of the Pharmaceutical Society of Great Britain state expressly that for ergot "the standard is a sample of ergotoxine phosphate which is kept in the dark *in vacuo* over phosphorus pentoxide." The adoption by the Society of this standard, in place of a sample of ergotamine tartrate, was also announced three years ago in a paper by Burn and Ellis (*Pharmaceutical Journal*, 1927, cxviii., 384), which constituted a report to the Chairman of the International Conference on the Biological Standardisation of Certain Remedies.

CONGRESS FOR SEX RESEARCH.

THE Second International Congress for Sex Research was held at the B.M.A. House from August 3rd to 9th. Over 200 members attended, and many countries were represented. Prof. F. A. E. Crew presided over the congress; Dr. Albert Moll, president of the International Society for Sex Research, was the only vice-president; Mr. B. P. Wiesner, Ph.D., acted as general secretary, and Mr. A. W. Greenwood, Ph.D., as publications secretary. Ten medical men served, among others, on the British organising committee, which arranged an admirably varied programme. The subject of the presidential address was Puberty and Maturity, and the subjects dealt with at the general session on August 5th included communications by Prof. Paul Bouin and Dr. J. Benoit (Strasbourg) and by Prof. H. C. Koch (Chicago) on the testicular

hormone, and by Prof. J. B. Collip (Montreal) on the ovary-stimulating substance of the placenta. On the following days the general sessions were devoted to papers and discussions on the influence of hormone therapy on sexual functions, opened by Prof. L. Fraenkel and Dr. E. Fels (Breslau); psycho-analysis and biology, opened by Dr. Ernest Jones (London); transformation of the sexual into the maternal instinct, opened by Prof. Carlo Ceni (Bologna), and the methods for the control of human fertility. The afternoons were mostly devoted to sectional meetings at which over 100 short communications were submitted on diverse subjects, ranging from biochemical studies of the sex hormones to special forms of sadism. On August 6th an excursion was organised to Cambridge, where at the School of Agriculture demonstrations were given by workers at this school and also by the Animal Genetics Department of the University of Edinburgh, and by the Strangeways Research Laboratories, Cambridge.

MEDICAL INSURANCE AGENCY.

A MEETING of the committee of management of the Medical Insurance Agency was held at the House of the British Medical Association on July 29th, when the report of the twenty-third year of the agency's work and the corresponding balance sheet were adopted. It was revealed in the report that the general progress of previous years had satisfactorily continued, an outstanding feature being the successful opening of the office in Scotland. The total premium income for the year approximated £98,000—an increase of more than £8000 as compared with the previous year—while 6500 renewals had to be dealt with. The commission from motor-car insurance continued to increase rapidly. Life assurance dealt with through the agency approximated during the year to two million pounds. The following grants were made to organised medical charities for 1930:—

		£	s.	d.
Royal Medical Benevolent Fund	..	630	0	0
Royal Medical Benevolent Fund Guild	..	630	0	0

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

THE annual meeting of the British Association, to be held at Bristol from Sept. 3rd to 10th, promises well. The sciences will be divided, as usual, into sections, of which this year 13 will meet concurrently in different rooms. The programme submitted is chronological, all sections being included, so that any member who gives it the study it deserves can pick out those communications likely to interest him and make plans to visit several sections on any day. Prof. F. O. Bower, F.R.S., Emeritus professor of botany (Glasgow), is this year's president and will deliver his address on Size and Form in Plants at the inaugural general meeting at Colston Hall on Sept. 4th. We have already called attention to certain notable addresses and discussions, which should yield a rich harvest, and would now stress the importance of many of the communications offered to Section J (Psychology). On the opening day of the meeting a discussion will be held on the Psychology of Adolescence, to which Prof. Olive Wheeler, Dr. R. G. Gordon, Miss A. H. McAllister, and Miss M. Phillips will contribute. On Sept. 5th Prof. C. W. Valentine (Birmingham) will deliver his presidential address on the Foundations of Child Psychology, and in the afternoon the shorter communications to the section will include a survey of the Place of Industrial Psychology in a University City, by Dr. C. S. Myers, F.R.S. Section J joins with Section I (Physiology) on Sept. 8th, when Mr. J. Drever, D.Phil., Prof. H. E. Roaf, Dr. R. J. Lythgoe, and Mr. J. H. Shaxby, D.Sc., will discuss the question, "In what sense can we speak of primary colours?" Other interesting papers to be read at this section include two on conditioned reflexes from the psychological point of view, by Dr. P. C. P. Cloake, and Dr. A. Wohlgemuth respectively; one on perseveration and the introvert, by Dr. W. J. Pinard; one on the psychophysics of desire, by Mr. C. A. Mace; and one on the psychology of the tuberculous patient, by Dr. H. Banister. A closer union between the ideas of those engaged in medical practice and those engaged in psychological research is one of the outstanding needs of the present time, and doctors who are members of the British Association should follow closely the activities of this section.

ON the passing of the Mental Treatment Act the Board of Control, with the approval of the Minister of Health, have appointed Mr. P. Barter (of the Ministry of Health) to be joint secretary of the Board. Mr. Barter was secretary to the Committee on Asylum Administration, 1921–22; the Royal Commission on Lunacy and Mental Disorder, 1924–26; and the Royal Commission on Local Government, 1928–29.

THE Royal College of Physicians of London will be closed for the summer vacation from Monday, August 18th, to Saturday, Sept. 20th, both days inclusive. In our advertisement columns application is invited for the office of Milroy lecturer for 1932. The course consists of three lectures on State medicine and public hygiene; suggestions for the choice of subject were left by Dr. Milroy in his will, and are at the disposal of applicants.

AN additional coroner, to be appointed for the County of London at a salary of £1700, will probably be allocated to the new northern division of the County.

Prof. G. Grey Turner has been invited to deliver the John B. Murphy Oration before the Clinical Congress of the American College of Surgeons in Philadelphia on Oct. 13th.

WE regret to announce the death in Belfast of Dr. John Elder MacIlwaine, professor of materia medica and therapeutics at the Queen's University and visiting physician to the Royal Victoria Hospital. He was in his fifty-seventh year.

BELFORD HOSPITAL.—The Duke of York, as Earl of Inverness, recently opened a new operating theatre at the Belford Hospital, Lochaber, Inverness-shire, as a memorial to Dr. Cameron Miller, who was medical superintendent for 41 years until his death in 1927.

CLINICAL INTERPRETATION OF AIDS TO DIAGNOSIS

A Series of Special Articles, contributed by invitation.

LXXXI.—THE CLINICAL SIGNIFICANCE OF SLIT-LAMP APPEARANCES.

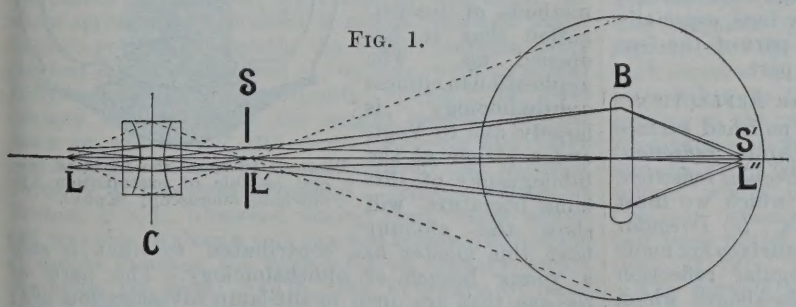
PART I.*

THE introduction of the binocular corneal microscope many years ago raised the hopes of the ophthalmic surgeon, in that it promised to be an instrument which, capable of 60–100 magnifications, might prove of great help in diagnosing conditions of the cornea and iris which were not visible with the ordinary corneal loupe of 8 to 10 magnifications. The result was that apart from a few observations of interest, especially in the lens by Hess, there followed very little increase in our knowledge.

In 1911 Gullstrand showed at the International Ophthalmological Congress at Heidelberg an entirely novel method of illuminating the anterior segment of the eye, which enabled the observer to see peculiarities in the structure of the vitreous and lens, even with quite low magnifications. The best results were obtained when there was a perfect control of the distribution of light and shadow. The essential point was to obtain a sharp image of a bright and uniform source of light, so beautifully focused that it might be projected upon that portion of the eye which we wished to examine and all other light shut out from the field. The examination had to be conducted, therefore, in a dark room, and various reflexes, from the highly polished refracting surfaces of the eye, excluded. The aim was to obtain first of all a sharply limited uniform source of light of high specific intensity, and secondly a sharp optical image of this source.

In the past we sought a uniform source of light for ophthalmoscopic examination, and this was obtained by using, in earlier days, the Argand gas burner or duplex petroleum lamp and in more recent days the frosted electric lamp with a closely wound filament. Neither of these sources of illumination was suitable because neither was of high intensity, neither were they at all uniform.

FIG. 1.

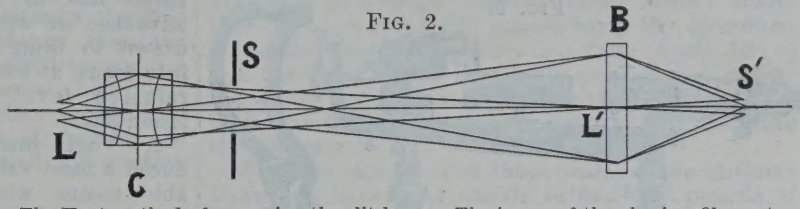


The Gullstrand method of arranging the slit-lamp. The image of the glowing filament (L) is formed in the slit (S L′) which is then focused upon the eye (S′L″) by means of the illuminating lens (B) (Meesman).

At the date of the invention of the slit-lamp there were only two sources of light (apart from sunlight) which were uniform—namely, the crater of the positive carbon of an arc lamp and the glowing filament of a Nernst burner. The arc lamp was so cumbrous at that date that its use was not practicable, consequently Gullstrand chose the Nernst lamp as his source of light. As the image of the source of light had to be used with a diaphragm, this diaphragm, made to enclose the image of the glowing filament, had necessarily to be shaped as a slit, and it was for this reason that the illuminating lamp was equipped with a slit.

The complete illuminating apparatus consists of the glowing filament enclosed in a tube at the other end of which is a slit of variable width. Between the two is a condensing system whereby an image of the glowing filament is projected in the slit. An image of the image of the glowing filament in the slit is projected upon the portion of the eye to be examined with an aspherical lens. (Fig. 1.) It is not possible to obtain Nernst lamps now and consequently some other source of illumination had to be devised, and so the Nernst lamp has been replaced by the Nitra lamp which consists of a tightly wound glowing spiral of tungsten in an atmosphere of nitrogen. The disadvantages of such a lamp are that the spiral does not produce a uniform source of light, it is seldom straight, and the glass globe deteriorates the optical image projected in the slit.

FIG. 2.



The Vogt method of arranging the slit-lamp. The image of the glowing filament (L) is formed on the illuminating lens (B). The image (S′) of the slit (S), filled with homogeneous light, is focused by the illuminating lens (B) upon the eye (Meesman).

The lens (the illuminating lens) which projects the image of the glowing filament in the slit upon the eye is fixed upon an arm which projects from the tube of the illuminating system (the arm of Henker). It is found that if the image of the filament itself be projected upon the illuminating lens then the slit acts merely as a diaphragm filled with homogeneous light, an image of which may be projected upon the eye by the illuminating lens. This method, known as that of Vogt, is the one usually adopted, and the aspherical illuminating lens is replaced by an achromatic lens severely diaphragmed (11 by 16 mm.) and having a focal length of 10 or 7 mm. (Fig. 2.) This prevents the light from being broken up and, having a small diaphragm, no trouble arises from spherical aberration.

The complete apparatus now consists of a luminous source, a condenser, a slit, and at the end of Henker's arm, which is 35 cm. in length, an achromatic lens of 10 to 7 cm. focal length. This apparatus is mounted on an arm attached to the pillar of a suitable table to which also is attached a chin and head rest for the use of the patient. In this way the head is immobilised, and the light can then be practically focused upon the portion of the eye we wish to examine. We use in connexion with this illuminating the Czapski binocular microscope, which has long been in use, but with only medium amounts of magnification, seldom more than 23 diameters. The microscope has an erecting mechanism in the eyepiece so that we observe upright images, a matter of great convenience. In connexion with the screw of the focusing arrangement is a device for measuring the depth of the anterior chamber. (Fig. 3.)

Methods of Examination.

It must not be imagined that the slit-lamp and microscope are together merely a piece of apparatus for practising a superior type of focal examination.

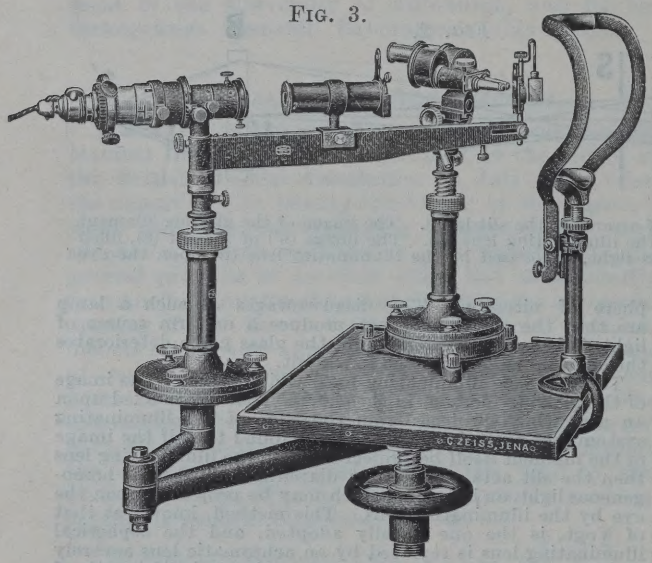
* Parts II. and III. will appear in subsequent issues.

It is true that this is one of its special functions, but owing to the peculiar transparent property of the parts of the eye open to investigation several other new methods of examination are open to us.

Examination in *focal light* is the easiest as well as the most useful method, and owing to the intensity of the illumination small opacities in otherwise what appear to be perfectly transparent structures may be exhibited by the principle of dark-ground illumination.

One new method is that of examination by *trans-illumination*. For this it is necessary that the structure to be examined should be transparent or at least translucent; it is also necessary that there should lie behind it a surface of sufficient polish to act as a reflecting or diffusing screen. Thus, to examine the cornea in this way we concentrate the light upon the portions of the iris or lens which lie behind it and certain changes in the endo- and

FIG. 3.



Gullstrand slit-lamp with Nitra lamp. The component parts—lamp, Koeppe tube, and illuminating lens—are mounted on the arm of Henker. The method fixing the apparatus to the table is shown, also the head and chin rest. The microscope may easily be moved into a desired position by sliding it over the glass plate.

epithelium are made much more apparent. The iris, if translucent by disease or injury, may be examined by light reflected by the surface of the lens, especially if it be cataractous, and the anterior part of the lens by light reflected by the posterior part.

EXAMINATION IN ZONES OF SPECULAR REFLECTION.

When light strikes a more or less polished surface it is reflected in three ways: (*a*) *Diffuse reflection*, whereby we can see the surface. (*b*) *Regular reflection*, whereby images are formed, to see which we must be in the path of direct reflection of rays. (*c*) *Irregular reflection*, whereby irregularities of the surface are made apparent. A good example of irregular reflection is shown by the glint seen on a blackboard which prevents one seeing the writing in the zone. If the position of the head be shifted then the glint will appear in another part of the board obliterating the writing here, whereas the writing in the previously obscured area will reappear. If attention be paid to each of the zones the irregularities of the surface, such as the grain of the wood or the marks of the brush, will be seen, and in this area alone. This peculiar phenomenon was first investigated by Vogt, and by its means the endothelium of the cornea may be seen with no more than 23 magnifications, and in some instances the nucleus of the cell may be seen.

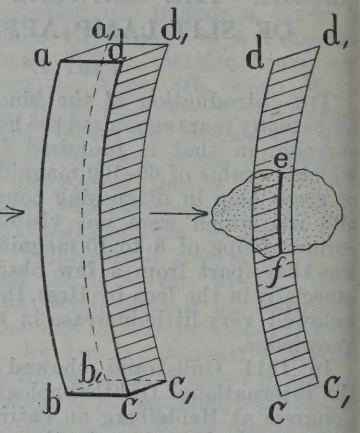
LOCALISATION IN DEPTH.

A most important advance in our means of investigating the translucent part of the eye is the means we now possess of deciding at what depth a lesion lies. This is one of the important functions of the slit-lamp and microscope. The two most important means available are:—

1. By *focusing the microscope* we may judge by the amount the microscope has to be advanced or withdrawn to bring it into focus, at what relative level a lesion lies.

2. Vogt introduced a most valuable means when he described the method of the *optical section*.

FIG. 4.



Localisation in depth by means of the corneal prism: (a b c d) = anterior band, (a,b,c,d,) = posterior band, (d c c,d,) = the optical section. If the slit be very much reduced in width the optical section becomes extremely thin, and by its means the depth of a lesion in the cornea or lens may be determined (Meesman).

The media of the eye are in no instance perfectly transparent and when the ribbon of light projected by the illuminating lens passes through them the path of the rays is easily visible, like a beam of light shining through an otherwise darkened room. Taking the cornea as our example, a parallelogram of light will be reflected by the anterior surface to the cornea and a corresponding one at the posterior surface, the intervening part scattering light so as to render the thickness of the cornea visible. The lateral face of the beam as it shines through the cornea is called the *optical section*, and if the slit be very much narrowed we may produce an illuminated layer of the cornea not more than 50 μ in thickness. (Fig. 4.) By judging what portion of the optical section first illuminates a lesion or foreign body we are able to decide at what depth it lies. The optical section is of importance in examining the lens and we shall see that here some remarkable discoveries have been made.

This brief account gives some idea of the origin of the slit-lamp and the methods of investigation that it has opened up. The application to clinical ophthalmology is largely due to Vogt, and a glance at the bibliography of slit-lamp literature will show the amount that this master has contributed to what is still a young branch of ophthalmology. The parts of the eye that are open to slit-lamp investigation are: (1) conjunctiva; (2) cornea; (3) anterior chamber; (4) lens; (5) anterior third of vitreous. (Fig. 5.) Taking these structures in order we shall see how the slit-lamp has revealed many new points of normal appearance, has elucidated points in diseased conditions about which we had already some information; but its chief value has been to allow earlier diagnosis as well as to point out entirely new conditions.

FIG. 5.

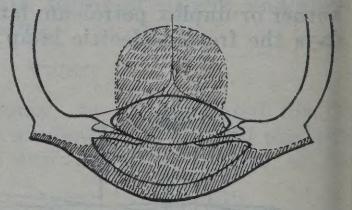


Diagram to show the parts of the eye capable of examination by slit-lamp microscopy (Koby).

Ophthalmic Surgeon to the London Hospital; Surgeon, Royal London Ophthalmic Hospital.

SPECIAL ARTICLES

A REPORT ON SEASONAL VARIATION IN THE GROWTH OF SCHOOL-CHILDREN.*

BY J. B. ORR, *D.S.O.*, *M.C.*, M.D., D.SC. GLASG.,
DIRECTOR OF THE ROWETT RESEARCH INSTITUTE;
AND
M. L. CLARK, L.L.A.
(*From the Rowett Research Institute, Aberdeen.*)

DURING the investigation on the effect of milk on the growth of school-children, already reported in this journal,[1 2] there was evidence that the increase in height and weight of the children was not distributed evenly throughout the period of the test. To obtain further information on what appeared to be a seasonal variation in the rate of growth, the periodic measurements were continued for another year.

Previous Work.

To Malling-Hansen [3] we are indebted for the first accurately recorded observations on seasonal growth in height and weight, though Buffon [4] had suspected that summer and winter growth in height in children might not proceed at an equal rate. In the children of a deaf and dumb institution in Copenhagen, Malling-Hansen, from painstaking daily observations extending over three years, found three main periods of growth (excluding the summer vacation weeks). These were:—

PERIOD.	HEIGHT.	WEIGHT.
Minimum ..	Mid Sept. to end Nov.	End April to mid July.
Medium ..	End Nov. to end March.	Mid Dec. to end April.
Maximum ..	End March to end June.	Mid Sept. to mid Dec.

He also noted that the greatest weight increase was during and just immediately after the summer holiday, while there might even be loss of weight in the period from April to July. Camerer,[5] on a few German children observed for several years, also noted seasonal differences in growth, with loss of weight in the warm spring days. Schmid-Monnard [6] likewise found distinct periods in growth, the weight increase being greatest in the second half of the year, with an actual decrease occurring in March. Bleyer,[7] in 1000 German infants, found the weight increase to slow down in winter and still more in spring and early summer, but to hasten in late summer and autumn. Porter,[8] in "several thousand" school-children in Boston, U.S.A., observed during their whole school life, was able to show a very marked seasonal difference in weight increase, the September to January period averaging (in boys) 3·40 lb., the February to June period 0·82 lb. He also found loss of weight in April, May, and June. Gebhart,[9] with Italian children in New York, showed a spurt of weight in autumn and arrest (but not loss) in spring. Frank [10] found a seasonal difference in height increase even in infants from birth up to two years; a rapid rise from April to June, slowing down in the hot summer months and still more in the winter months. v. Wendt,[11] on 15,000 children in Finland aged from 11 to 16 years, found a maximum increase in height from June to September, in weight from October to January; a minimum in both height and weight from February to May. Emerson,[12] on the contrary, from records of over 800 children in such different centres as Honolulu, Toronto, and New York, could find no difference in the rate of increase in height throughout the year, nor any correlation between the rate of increase in weight and the sunshine record in each city. He considers fluctuations in weight most probably due to infections and hygienic conditions, not to biologic reasons. Corry Mann [13] found that, in a group of 220 school boys, the increment in height during summer—i.e., from April 1st to Oct. 1st—was almost invariably greater than during the winter period from Oct. 1st to April 1st, and that there was also usually a greater gain in weight during the summer.

With the exception of these observations of Corry Mann, we have been unable to find any records of seasonal differences in growth of children in Scotland or England. The following observations, though on rather small numbers (657), are offered as a contribution to the existing data on this subject.

Present Investigation.

The children on whom the observations were made were attending public day schools in Glasgow, Edinburgh, Dundee, Peterhead, and Greenock.

METHOD.

The measurements were taken in the second and third weeks of December, 1928, March, June, September, and December, 1929. The children measured were from 7 to 11 years of age. They had received no supplementary feeding since June, 1928, and were therefore on their ordinary home diets.

All the measurements were taken by one observer, the centres visited in the same rotation, and children weighed and measured at the same time of day on each occasion, without shoes, but with indoor clothing. The average weight of clothing at each weighing was computed by the method described in the previous report,[1] and the difference allowed for in calculating each increase in weight of the children. The weights were taken to the nearest quarter of a pound, the heights to the nearest eighth of an inch. With these precautions it was hoped to ensure accurate records and to avoid the daily fluctuations in height and weight which previous observers (Malling-Hansen, Camerer, among others) had recorded, and which had been noted in the Scottish children in the milk tests (1), (2).

The periods were: (1) From December, 1928, to March, 1929. (2) From April, 1929, to June, 1929. (3) From July, 1929, to September, 1929. (4) From October, 1929, to December, 1929.

In the case of children who had suffered any serious illness the data were omitted from the records. The data for the Greenock children were also omitted, owing to the fact that the machine on which the weighings and measurings were done was changed after the first observations, and there was some doubt about the accuracy of the yardstick on the first machine which was not checked. The data were calculated separately, and though the results do not

* Part of the expenses of this Survey was defrayed by a grant made to the Department of Health for Scotland by the Empire Marketing Board. The Nutrition Committee of the Medical Research Council were kept informed of the progress of both this and the previous investigation on the effect of milk on school-children, and acknowledgment is made for the helpful advice and criticisms obtained from the Committee, who are, however, not in any way responsible for the accuracy of the data or views expressed.

differ materially from those recorded from the other four centres, owing to the element of doubt as to their accuracy, it was necessary to omit them.

RESULTS.

The cards used were first of all divided into age-groups for each sex, irrespective of centre, and the mean increase in height and weight during each period were calculated. The results are given in Table I.

TABLE I.—*Height: Mean Increase in Inches.*

Age in years.	Number.	Period— I. (Dec.–March).	II. (April–June).	III. (July–Sept.).	IV. (Oct.–Dec.).
		Boys.			
7	59	0·4301	0·8518	0·5357	0·3773
8	40	0·4969	0·7535	0·5031	0·3081
9	26	0·4952	0·7396	0·4243	0·3542
10	111	0·4189	0·6898	0·5172	0·3010
11	70	0·3893	0·6848	0·4729	0·3114
		Girls.			
7	68	0·4926	0·7701	0·4909	0·3894
8	52	0·4809	0·7572	0·4828	0·3750
9	25	0·4700	0·7500	0·4375	0·3287
10	139	0·3858	0·7284	0·4991	0·3265
11	67	0·4123	0·7271	0·5438	0·3667

It will be seen that in every case the greatest increase in the year is in the second period (April, May, June); the smallest increase in the last period (October, November, December). In seven out of ten groups the third period (July, August, September) has the second greatest increase; also in seven out of ten groups the first period (January, February, March) has the second lowest increase.

Table II. gives the data for the boys of all ages combined and for the girls of all ages combined.

TABLE II.—*Height: Mean Increase in Inches.*

—	Period— I. (Dec.–March).	II. (April–June).	III. (July–Sept.).	IV. (Oct.–Dec.).
	Boys (all ages).			
Number ..	306	291	275	280
Av. increase	0·4298 ±0·008	0·7309 ±0·008	0·5063 ±0·006	0·3239 ±0·007
S.D.	0·2097	0·1960	0·1455	0·1644
	Girls (all ages).			
Number ..	351	332	328	332
Av. increase	0·4318 ±0·008	0·7417 ±0·008	0·4959 ±0·006	0·3558 ±0·005
S.D.	0·2098	0·2237	0·1616	0·1478

As is seen from Table II., in both sexes the sequence in growth in height is the same; the increase is greatest in the second period, slackens considerably in the third, still more in the fourth, and begins to rise again in the first. When tested statistically, the difference between the increase at any two periods is significant, even in the case of the smallest difference—i.e., between periods I. and III. The period of maximum growth is thus in agreement with that found by Malling-Hansen and Frank in countries with seasons approximately the same.

Table III. gives the data for weight increase separately for the different ages.

The increases in weight do not correspond from age to age so closely as the increases in height. In six groups out of ten the greatest weight increase is at weighing III. (after the summer holiday); in five groups the second greatest increase is made in period IV., the third greatest in period I., and in six groups the smallest in period II.

TABLE III.—*Weight: Mean Increase in Pounds.*

Age in years.	Number	Period. I. (Dec.–March).	II. (April–June).	III. (July–Sept.).	IV. (Oct.–Dec.).
		Boys.			
7	59	1·2670	1·1342	1·3061	1·3046
8	40	1·6000	0·3750	1·4688	1·3546
9	26	0·8750	0·9688	1·5313	1·5937
10	111	1·7387	0·5764	1·8236	1·3835
11	70	1·3286	0·8043	2·0208	1·5682
		Girls.			
7	68	0·8603	1·0936	1·7182	0·8360
8	52	0·9279	1·3413	1·2549	1·2600
9	25	0·5800	1·7174	1·6250	1·7500
10	139	1·0665	1·0213	1·9421	1·3358
11	67	1·3023	1·2083	2·2083	1·4084

Table IV. gives the data for the boys of all ages combined and for the girls of all ages combined.

In both sexes much the greatest increase in weight is made in the period that includes the summer holiday; the difference between this increase and that of any other period is statistically significant. The boys make in the first period an increase slightly, but not significantly, greater than the fourth period; the girls in the fourth period an increase significantly greater than that of the first period but not than that of the second. The small increase made by the boys in the second period is remarkable. Questions at the June weighing brought out the fact that many children, and more particularly the boys, were practising for school sports.

TABLE IV.—*Weight: Mean Increase in Pounds.*

—	Period— I. (Dec.–March).	II. (April–June).	III. (July–Sept.).	IV. (Oct.–Dec.).
	Boys (all ages).			
Number ..	306	291	275	280
Av. increase	1·4677 ±0·048	0·7423 ±0·049	1·7070 ±0·051	1·3741 ±0·050
S.D.	1·2609	1·2463	1·2582	1·2551
	Girls (all ages).			
Number ..	351	332	328	332
Av. increase	1·0149 ±0·048	1·1674 ±0·045	1·8268 ±0·048	1·2808 ±0·049
S.D.	1·3467	1·2199	1·2943	1·3230

The cards were scrutinised as to numbers showing no gain or definite loss of weight in the different periods with the following results:—

Period.	*Boys.* Per cent.	*Girls.* Per cent.
I. (Dec.–March)	12·4	22·7
II. (April–June)	23·2	16·8
III. (July–Sept.)	6·5	4·7
IV. (Oct.–Dec.)	12·5	16·5

HEIGHT AND WEIGHT PERIODS COMPARED.

On comparing Tables II. and IV. it is seen that the period of greatest increase in height is not that of greatest increase in weight, nor that of least increase in height that of least increase in weight. Quite definitely the greatest weight increase is in the period following the greatest height increase, as is seen in the

graph. Dividing the increase into two periods, instead of into four there is a very decided difference, in both sexes, in both height and weight.

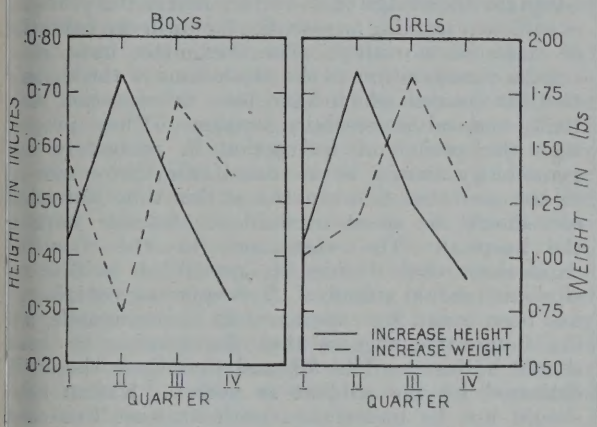
HEIGHT INCREASE (INCHES).

	Boys.	*Girls.*
March–September	1·2372	1·2406
September–March	0·7537	0·7876

WEIGHT INCREASE (IN POUNDS).

	Boys.	*Girls.*
June–December	3·0811	3·1076
December–June	2·2100	2·1823

The increase in height from March to September is almost half an inch greater than that from September to March. The increase in weight is nearly one



pound greater in the second half of the year than that in the first half. The periods of increase in height and weight are shown to be not coincident, but subsequent.

Summary.

(1) Children to the number of 657, aged from 7 to 11 years, from four Scottish towns were measured and weighed in quarterly periods. (2) They showed a very much greater increase in height in the three months from the end of March to the end of June than in any other period, and the smallest increase in height in the months of October, November, and December. (3) The weight increase was greatest in the quarter July, August, September; second greatest in the quarter October, November, December. (4) In the early summer quarter (April, May, June) about 25 per cent. of the boys actually lost weight although increasing in height.

Note.—Since this report was drawn up a paper has been published by Gustav Nylin,[14] giving observations on the growth of Swedish school-children. His results show a seasonal variation in growth, the maximum height increase being from March to May. They also show that maximum increase in height is associated with minimum increase in weight. The results are, therefore, in general agreement with those presented above.

MATERNAL MORTALITY AND MORBIDITY.

INTERIM REPORT OF DEPARTMENTAL COMMITTEE OF THE MINISTRY OF HEALTH.

(*Concluded from p. 324.*)

A National Maternity Service.

IN the eighth chapter of the interim report the history of the gradually increasing interest taken by the State in the provision of an adequate maternity service for the whole nation is outlined. Since 1919 there has been created under the Ministry of Health a maternity service of considerable magnitude, and in 1924 a circular was issued recommending antenatal supervision by the practitioner and midwife, the provision of sufficient maternity beds for abnormal cases by the local authorities, supervision under the Midwives Act of practising midwives, investigation of cases of maternal mortality and morbidity, and the dissemination of educational propaganda to the public. In considering the question of maternity benefit the Royal Commission on National Health Insurance decided that ultimately medical, nursing, and institutional services of all kinds should be administered by the local authorities as a part of the medical service, and that cash benefit should be administered separately from this by the approved societies. In addition, the majority report recommended that as soon as funds became available maternity benefit should be expanded to cover medical and midwifery services as well as cash payment. In 1929 the British Medical Association published a scheme for a national maternity service, and the Departmental Committee on the Training and Employment of Midwives produced a similar scheme. In setting out their recommendations for a national service, the Departmental Committee on Maternal Mortality and Morbidity have had both these schemes under consideration, and it is of interest to note the resemblances and differences between the various schemes.

SCOPE OF THE SERVICE.

In the scheme provided by the British Medical Association as well as in that now formulated by the Committee, the service is designed to apply, not only to insured persons, but to all those not in a position to procure for themselves similar benefits by private arrangement. The service would entail coöperation between the medical profession and practising midwives, probably with representation of both on the committees or subcommittees concerned. The essential points in such a scheme would be the provision of medical antenatal and postnatal supervision, the services of the midwife in every case, and her attendance on normal cases, provision of a consultant when desired by the doctor, and adequate hospital accommodation for those cases which require institutional care. The education of the expectant mother must play an important part in the scheme, since experience shows that neglect of the services available is a potent factor in raising maternal mortality.

POSITION OF THE MIDWIFE.

By the provision of a trained midwife at every labour, whether a doctor is in attendance or not, it is hoped to eliminate the dangerous "handy-woman." The duties of the midwife will be to book the case, to inform the local authorities, to arrange for medical antenatal examinations, to attend the patient during

labour, and to advise her on general hygiene and the value of a postnatal examination. In the British Medical Association scheme it is specially laid down that the midwife should not send the patient to hospital or requisition a consultant on her own responsibility. In order that a sufficient number of well-trained midwives may be available the Departmental Committee, in their scheme, recommend obligatory courses of post-certificate training, and the limitation of the number of cases attended in one year to 100 or 110. They further suggest closer and more helpful supervision, and consider it advisable that eventually all midwives should be drawn from the ranks of State-registered nurses.

POSITION OF THE PRACTITIONER.

The Committee consider that the practical experience of the medical student in midwifery is too meagre and that his work when he is qualified and in practice is often handicapped by adverse economic conditions in the homes of his patients; they therefore recommend adequate payment for obstetric work and better educational facilities. They do not consider that the practice of obstetrics should be limited to a selected panel of practitioners, but that it should be open to the whole profession, as at present. In some areas, however, they think select practitioners working in conjunction with the extern departments of training hospitals might participate in the service, so long as the mother retained her right to a free choice of doctor. The conditions of service for all practitioners would entail the establishment of an advisory medical committee, and the provision of special post-graduate courses in obstetrics. The Committee suggest remuneration by means of an inclusive fee, and differ in this from the British Medical Association, in whose scheme separate fees for antenatal examinations, for confinements, and for postnatal reports are proposed. Another difference arises between the two schemes over the question of antenatal examinations; the Association stipulates that at least one must be made, while the Committee require one at the sixteenth, one at the thirty-second, and one at the thirty-sixth week. In the conduct of postnatal examinations, moreover, the Committee demand a complete investigation of the pelvis and of the general medical condition, while the Association asks merely for a consultation, with examination if necessary. The treatment under the scheme of abnormalities found at the postnatal examination is considered as a probable measure by the Committee. An adequate consultant service is held to be essential under both schemes, the British Medical Association adding a provision that the consultant should usually be obtained locally.

INSTITUTIONAL TREATMENT AND NURSING SERVICES.

The provision of sufficient beds for all abnormal cases and for those normal cases living in unsuitable conditions will be required as part of a complete service; the Association believes that the general practitioner should have the right to follow and attend his patient in hospital, but though the Committee are entirely in sympathy with this principle they feel that the responsibility for the standard of work at any institution should rest in the hands of one person only. The question of sickness benefit for the mother has not yet been considered in detail by the Committee. The possibility that the district nurse might combine midwifery with her general work under the scheme is accepted, provided that the types of sick cases she is attending are suitably restricted; the provision of "home-helps" for the mothers is recognised as desirable. A different fate for the present antenatal clinics is foreshadowed under the two schemes; the Committee see them as centres for consultation between the general practitioner and the obstetrician, while the Association considers that they should develop into centres for training in mothercraft, with the possibility that they might be used in some areas by the general practitioners for the examination of their own cases. The finances of the scheme have not been included in the Committee's report, but have been covered in the scheme put forward by the Association.

Medical Education in Obstetrics.

The importance to the general practitioner of an adequate knowledge of midwifery makes the provision of sufficient training an essential factor in the reduction of maternal mortality. The Committee have given careful consideration to the resolutions of the General Medical Council which have been in operation since 1923, and advise certain revisions. They propose that the period of instruction in midwifery and gynæcology should be increased from three months to six, and that two months of this time instead of one should be spent in resident obstetric work in the hospital. The statement in the Council's regulations that during his period of residence a student "should attend. . . . . twenty cases of labour" has been found by experience to be ambiguous, and the Committee suggest that the number of cases should be increased to 30, and that these should be delivered by the student in person. Extern cases should not be undertaken until at least five cases have been delivered under supervision in the ward. Throughout his six months' training, which should follow six months' work as a surgical dresser, the student should receive systematic instruction in midwifery and gynæcology, so arranged that two-thirds of the time is allotted to midwifery; antenatal work should include the personal examination under supervision of not less than 50 pregnant women, and for instruction in infant hygiene the student should attend at least eight times at an infant welfare centre. Before taking his final examination he should present a certificate stating that these various conditions have been fulfilled, and giving the official position of the certifying officer. Throughout his course the Committee are most anxious that the student should be impressed with the importance of preventive measures in midwifery. The shortage of cases may give the Committee's recommendations the appearance of a counsel of perfection, but they believe that a large number of cases are at present absorbed in training pupil midwives, many of whom do not intend to practise. A redistribution of cases with access, in addition, to the cases confined in council hospitals would, they believe, solve this difficulty.

Anæsthetics in Midwifery.—Puerperal Sepsis.

The Committee consider that light intermittent anæsthesia may be administered to a greater extent than has been the custom up to the present time in normal cases, particularly to primiparæ; such administration should, in their view, be limited to the latter part of the second stage of labour, and should be undertaken by the doctor only. They hold that an increase in the employment of anæsthesia, unless wisely directed and controlled, may lead to an increase in mortality and morbidity. Appendices A, B, and C, which give memoranda on this subject received from the Royal College of Physicians of London, the British College of Obstetricians and Gynæcologists, and the British Medical Association, deserve careful study. The first-named body state

clearly the view that though there are limitations to the wide and general use of sedatives, analgesics, and anæsthetics for the relief of pain in natural labour, if they are administered in hospital under proper medical supervision, the contra-indications are negligible. The British College of Obstetricians and Gynæcologists believe that it would be a simple matter for a fully certificated nurse to receive instruction in the administration of *light* inhalation anæsthesia during her six months' training in an obstetrical hospital or department. They do not think it right for a midwife possessing only the C.M.B. certificate to be entrusted with such a duty, and hold that *deep* inhalation anæsthesia and all other methods of anæsthesia should be administered only by a qualified medical practitioner.

Among the recommendations made by the Committee for measures to limit puerperal sepsis is the proposal that all lying-in hospitals should have facilities for the separation of normal, suspected, and pyrexial cases. This may be accomplished by means of three individual units with separate staffs, one reserved for clean cases, one for cases of sepsis, and one for emergencies. More care in the sterilisation of the hands and the routine use of gloves are advised, as well as a thorough physical examination of the pupils and nursing staff, including a bacteriological investigation of their noses and throats. They emphasise the urgent necessity for more available beds, and for their concentration in a smaller number of hospitals, by which measure it is hoped to increase the facilities for research.

Antiseptic Toilet.

Appendix D contains a memorandum by Dr. L. Colebrook on the sterilisation of the hands. His experiments show that the initial antiseptic toilet as commonly advocated in this country—viz., thorough washing, followed by treatment of the hands for three minutes with perchloride of mercury (0·1 per cent), or lysol (0·62 per cent.) of good quality, will usually succeed, *if it is conscientiously carried out*, in getting rid of any hæmolytic streptococci with which the hands have become contaminated. Washing alone removes the greater number of such streptococci. These procedures do not, however, sterilise the hands in the bacteriological sense. Staphylococci, and sometimes diphtheroid bacilli, can still be cultivated from them. Moreover, as a means to the elimination of streptococci, this antiseptic toilet offers only a small margin of safety. If the washing is perfunctory, or the strength of the antiseptic solutions is reduced, or, again, if the streptococcal contamination of the hands is a heavy one and combined with serous discharges, killing is likely to be incomplete. He notes that iodine (0·5–1 per cent.) or chloramine T (1 per cent.) is more efficient for killing hæmolytic streptococci on the hands than either perchloride or lysol and should be tried, though their use is open to some objections (smell, staining &c.), and it is not unlikely that they would be found too irritant for frequent use. The problem of re-sterilisation of the hands at intervals is even more difficult. The midwife needs for this an antiseptic solution which can be relied upon to kill streptococci on the hands quickly—i.e., within two or three minutes at most—*and without previous washing*. Only iodine and chloramine T have been found to fulfil this condition.

His final conclusion is that in the interests of safer childbirth it is desirable that rubber gloves should be much more widely employed in all midwifery work. Smooth thin gloves can now be bought very cheaply, and, if not heated, wear well. Their sterilisation on the hands is very readily effected, with or without washing—e.g., by perchloride of mercury (0·5 per cent.) or biniodide in spirit (0·4 per cent.) or carbolic acid (1 per cent.).

EUGENIC STERILISATION.

A SHORT time ago the Eugenics Society appointed a "Committee for Legalising Eugenic Sterilisation," and this committee has now published a statement of its position. The pamphlet[1] reviews, first of all, the facts concerning the inheritance of mental deficiency. The three arguments which are adduced in favour of sterilisation as an urgent measure at the present moment are: (1) the inheritance of primary amentia; (2) the fact that high-grade mental defectives are incapable of regulating the birth of children; and (3) the substantial increase in mental deficiency during the last 20 years. The committee emphasise at the outset that their object is to remedy the ambiguity in the law, for it is doubtful whether eugenic sterilisation is or is not at present illegal. They are most anxious not to prejudice the activities of those who work for improved ascertainment, modern institutional accommodation, and better community care, for they are in entire sympathy with these measures, but they consider that sterilisation should be joined to them.

The first section of the pamphlet is devoted to a summary of the views of various authorities on the transmissibility of mental disease. Dr. E. O. Lewis concluded that the feeble-minded high-grade defectives, who comprise some 75 per cent. of the whole, tend to spring from a group composing roughly one-tenth of the total population, who are all subnormal and retarded though not necessarily defective: the "social problem" group. If the fertility of this group could be somehow limited, it is obvious that the number of feeble-minded in the country would be reduced. Quite apart from eugenics, these people bring up their children badly; they live in conditions of squalor and suffer from dirt diseases. Moreover, they are highly fertile and their birth-rate has been little influenced by the broadcast information on contraception. The birth control clinic has been powerless to reach them. Although under natural conditions the children of these people have a high mortality-rate, the maternity and child welfare work of the last 50 years has considerably reduced that mortality. In brief, therefore, the defective-producing class is multiplying at a much greater rate than any other class in the community.

The Harmlessness of Sterilisation: Legal Position.

The report hastens to contradict the erroneous view that sterilisation involves castration, and to explain the operations of vasectomy and division of the tubes. Electrical cauterisation of the tubal openings is mentioned, since it promises to make the sterilisation of the female as simple as that of the male. The legal position has been very well stated by Mr. Justice Humphreys, who was consulted by the British Medical Association. He said:—

"I am clearly of opinion that any medical man who performs the operation described upon a 'defective' within the meaning of that term as defined within the Mental Deficiency Act, 1913, would in the present state of law be

[1] The Eugenics Society, 20, Grosvenor-gardens, London, S.W. Pp. 32. 6*d*.

acting illegally and without any legal justification. I assume the consent of both parents and the excellence of the motives of all concerned, but the fact remains that the operation of sterilisation involves an assault upon and the wounding of the person operated upon. The only legal justification for such an action in regard to a person who . . . . is incapable of giving a reasoned consent, would be that the operation was necessary to the health or well-being of the patient. I do not gather from the case that it is contended that sterilisation would improve the condition, physical or mental, of the defective. The legal risks involved in such an operation would attach equally to all the persons concerned. . . . A jury might be disposed to take the view that in the public interest the conduct of the defendants was excusable, and even praiseworthy, and mitigate the damages accordingly, but, it must not be forgotten, the operation would have deprived the defective of a function which the law nowhere denies to him or her. On the contrary, the elaborate provisions of the Mental Deficiency Act for the safeguarding of such persons might be invoked as indicating that the only means sanctioned by the law of obtaining the desired end—viz., preventing the propagation of the unfit—consists in the segregation of such persons in licensed institutions."

Mr. Justice Humphreys does not refer to voluntary sterilisation, but Lord Riddell has expressed the opinion that it is illegal and constitutes a maim, and is thus a serious offence against public policy. It is, of course, undisputed that sterilisation in the interests of an individual's own health is perfectly legal, and there is some authority for believing that voluntary sterilisation would not be regarded as illegal. Ambiguity, however, remains, and needs to be cleared up before any great advance can be made towards a public policy of sterilisation.

Experience of Other Countries.

The sterilisation laws of the United States, Canada, Switzerland, and Denmark are reviewed. In 19 of the United States the purpose of the laws is both eugenic and therapeutic; in 6 it is purely eugenic, and in 2 it is eugenic, therapeutic, and penal. Seven States provide for compulsory sterilisation only, 7 for voluntary and compulsory sterilisation, and 5 for voluntary sterilisation only. As already stated in these columns,[2] 8515 operations have been officially performed in the United States up to Jan. 1st, 1928, and a careful review of the results is said to have given grounds for a satisfactory report. The evils feared by many people have not been found to follow eugenic sterilisation. The first European legislation was passed in the Canton de Vaud in 1928, and authorised the sterilisation of hereditary sufferers from mental disease or feeble-mindedness. The operation has been quite often performed privately, and the enactment in effect extends the benefits of sterilisation to those unable to pay. No results are as yet available from Switzerland. A Bill regulating eugenic sterilisation in Denmark was passed in the summer of last year in response to the pressure of public opinion. It has some unusual features; for instance, it permits a person convicted of indecent assault to ask in writing for castration. His demand may be granted on the recommendation of specialists and performed at the expense of the State. Mental patients returning to their homes and feeble-minded persons on parole may be sterilised without the consent of their relatives and on the recommendation of the director of the institution, but if an objection to the operation is raised they may be kept in the institution at the discretion of the director. Agitation for eugenic sterilisation laws is being carried on in New Zealand, Sweden, Norway, Germany, and Czecho-Slovakia; a law should come before the legislature of Sweden this year.

[2] THE LANCET, 1929, i., 924, 935.

Arguments For and Against.

The great argument for sterilisation is, in the opinion of this committee, the report of the Mental Deficiency Committee. The arguments against are briefly reviewed and countered. The grossly exaggerated idea that those who believe in sterilisation wish to sterilise every defective they can find and close down the institutions is refuted. Pessimists have argued that sterilisation cannot materially affect the number of mental defectives born, since so many of them come from apparently normal stock; but this point of view has been strongly challenged. On the most unfavourable assumption, it has been calculated that, if all primary aments ceased breeding, the incidence of defect could be reduced by as much as 17 per cent. in a single generation. The rate of elimination would, it is believed by the Committee, in practice be much greater. Defectives rarely produce normal children, and there is no single case on record of two mentally defective parents producing even a gifted or talented person, much less a genius. There is some ground for the argument that if genius is going to be suppressed at all, it will be suppressed by the practice of contraception among the educated classes and not by the sterilisation of the defectives or even by the voluntary sterilisation of the recovered insane. The idea that sterilisation might encourage promiscuity and disseminate venereal disease has not been confirmed by the experience of the United States, and the committee believe that the fear is not justified.

Proposals of the Committee.

The Mental Deficiency Committee proposed that institutions should be regarded rather as flowing lakes than as stagnant pools. Even if the present accommodation were quadrupled, it would probably at a given time accommodate only one-third of the total defective population of the community. The remaining two-thirds should have passed through the institution for stabilisation and training. The Eugenics Society's committee suggest that each defective, before being passed out into the community, should go before a board, which would consider his records in detail and would attempt to persuade him to submit to sterilisation if they thought there was the smallest risk of his becoming a parent. The Board of Control represents the view that guardianship would be a sufficient safeguard for these discharged defectives. The committee feel that this is expecting a great deal; a child may be conceived in a very few minutes, and guardians and supervisors cannot shadow their charges night and day. The committee emphasise the fact that their proposal does not militate against the policy of improving institutional provision. They hold that provision should also be made for the voluntary sterilisation of sufferers from those hereditary mental disorders which come under the heading of insanity, and propose to draft a Bill embodying these ideas. The Bill would provide for voluntary sterilisation in all cases, except that a defective of such a low grade as to be incapable of giving consent might be sterilised with the consent of his relatives on discharge from an institution. In actual practice it is rare for such low-grade cases to be discharged. A third clause would permit voluntary sterilisation of persons suffering from grave physical disease transmissible to children. A full bibliography of eugenic sterilisation is provided.

AN X RAY ROOM FOR HARROW HOSPITAL.—Kodak Ltd., whose works are at Wealdstone, in the area served by Harrow Hospital, are giving up to £1000 for the building and equipment of an X ray room at that institution.

PUBLIC HEALTH SERVICES

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE usual Circular (1119), containing instructions from the Ministry of Health on the annual reports expected from medical officers of health for 1930, were issued in June instead of in December this year in order to give time for the preparation of the extra information asked for. The 1930 report is to be a survey report but of a more simple character than that issued for 1925. Full information is asked for, on lines indicated in an appendix, on the transfer of poor-law functions in pursuance of the Local Government Act, 1929. In view of the proposals of the Government with regard to housing, special attention is to be given to housing defects and the compilation of accurate records with regard to the housing position.

The following are 1929 statistics of two south-coast and one east-coast county borough, and of three county boroughs on or near the Lancashire coal-field.

Name of district and estimated (R.-G.) mid-year population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Infant and neonatal mortality.	Young child (1–5 yr.) mortality.	Maternal mortality from childbirth.
Brighton .. (146,800)	13·4	14·5	0·98	1·79	2·4	2·8	55/26	23	2·5
Hastings .. (62,620)	12·2	15·9*	0·83	2·36	3·3	3·0	35/18	17	1·3
Gt. Yarmouth (58,110)	14·8	14·4†	0·98	1·72	2·7	2·6	59/25	29	4·6
Blackburn .. (125,300)	12·4	14·9	1·01	1·53	3·9	2·5	80/33	45	9·6
Stockport .. (127,800)	13·3	13·9	0·95	1·59	3·1	2·5	91/47	40	6·5
Bury .. .. (56,830)	13·6	16·4	0·81	1·71	4·2	3·3	79/48	44	6·4

Registered stillbirths per 100 live births: Brighton 4·2, Hastings 3·1, Gt. Yarmouth 2·9, Blackburn 4·8, Stockport 5·6, Bury 5·3.

*Standardised 11·4. †Standardised 12·0.

Noteworthy features of this table are the fact that the low birth-rates and influenza have abolished the natural increase of the populations, and the much smaller chance of survival for children born in the three northern towns.

Brighton.

Dr. Duncan Forbes expresses his regret that the form of report laid down by the Ministry of Health, which is convenient for national and comparative purposes, entails an aggregation of tables which makes dreary reading.

The conditions of housing have steadily improved in Brighton, but there are still cases of five or six sleeping in one room. Since the war the corporation have built 1726 houses and private enterprise 1656. The corporation houses completed in 1929 numbered 246 and 252 more were in course of erection. Over 5 per cent. of these houses are not kept clean, the worst tenants being slum-dwelling families removed with the hope of an improvement in good surroundings. The rent charged to such tenants is 12*s.* per week, for a three-bedroom non-parlour house, but they cannot usually pay more than 8*s.* The number of tuberculous patients requiring refills, after artificial pneumothorax, is on the increase. During the year 22 refills were given at the dispensary and 108 at the sanatorium. Applications for refills from patients operated on elsewhere are complied with. The tuberculosis officer, Dr. A. Neville Cox, considers light treatment unquestionably beneficial in most forms of non-pulmonary tuberculosis, usually after very prolonged treatment. He is not satisfied that artificial light is better than heliotherapy for tuberculous glands, joints, and peritoneums, but it is more dependable and more convenient for patients at work. In lupus and where there is pulmonary disease artificial light, he thinks, has the advantage. Most of the antenatal work is done at the Sussex Maternity and Women's Hospital, antenatal examination being one of the conditions of booking. This hospital employs 20 certified midwives and the number of Brighton patients attended by them was 751. The hospital admitted 117 Brighton patients under an agreement by which the council pays 7*s.* 6*d.* per day. The total cost was £632, of which £359 was paid by the patients and the Sussex Provident Scheme. Up to the end of 1929 sections of the livers of 202 stillbirths had been examined and spirochætes were found in 12 of them. It is concluded that general practitioners do not treat syphilis, since no doses of salvarsan substitute were applied for by them. Doses were, however, supplied to two specialists. An effort is being made to try out a better system of refuse removal with special bins and carts. During the year 12 out of 75 samples of milk examined were found to be tuberculous.

Hastings.

Dr. G. R. Bruce reports that the most used infant welfare centre will be swept away by the Front Line Improvement Scheme, and that it will be difficult to obtain central premises accessible for the mothers of the Old Town. Antenatal work continues to increase, but full use is not as yet made of the 12 beds at Fernbank Maternity Home. The open-air school has given very good results and a second one is to be established for 30 delicate children from the St. Leonard's side of the borough. The Orthopædic Scheme, with the Royal East Sussex Hospital as base, continues to work smoothly and dealt with 52 Hastings cases during the year. Of these, 23 were of pre-school age, 21 were school-children, and 8 were tuberculous. The patients included 11 congenital conditions, 7 cases of infantile paralysis, and 12 of rickets. No new municipal houses were erected, but towards the end of the year the corporation secured an excellent site and a start is to be made with 100 houses. There is a waiting-list of about 600, many of whom live in overcrowded sub-let rooms, in cottages of a low sanitary standard, or in basements. Some of these with large young families cannot pay the rents of municipal houses. Dr. Bruce considers there is a good field locally for the reconditioning and renovating of existing houses, and he would like to see this type of housing reform taken up by private enterprise or a public utility society. Immunisation against diphtheria was adopted with satisfactory results in an institution where there had been a succession of cases for a period of over six months. During 1929 Hastings had 2002·7 hours of bright sunshine and a rainfall of 31·58 inches, this being 3·75 inches in excess of the normal.

Great Yarmouth.

Dr. A. N. Stevens says the hours of bright sunshine recorded were 1624·4 and the rainfall 18·73 inches, as compared with an average of 24·8 inches. Over 57 per cent. of the deaths of Yarmouth residents occurred at ages above 65, and over 32 per cent. at ages above 75. Two-thirds of the confinements in Great Yarmouth are attended by medical practitioners and only one-third by midwives. The Notification

of Births Act is not enforced. Of 865 births, 219 were not notified. The 307 births attended by midwives were all notified. Apparently the notification of puerperal fever is in the same position, seeing that there were four notifications and three deaths. Inquiries made showed that 95 per cent. of 787 babies were breast-fed during the first month and that 78 per cent. of 619 were breast-fed during the fourth month. A difficulty was experienced in filling vacancies for health visitors for nearly the whole of the year. Diphtheria was more prevalent than during any year of the last decade. There were 107 notifications and three deaths. From March to June 22 cases occurred in the East Anglican School for Blind and Deaf Children, and in consequence immunisation was offered for all the scholars whose parents gave their consent.

Blackburn.

Dr. V. T. Thierens submits a table showing that the birth-rate has declined nearly 50 per cent. during the last 10 years; that twice during that period there has been a natural decrease of population, namely, 1·3 per 1000 in 1927 and 2·5 in 1929; also that during the remaining 10 years the highest natural increase was 8·2 per 1000 in 1920, and the lowest 1·0 in 1925. He states that owing to trade depression comparatively large numbers leave the town. The chief industry is cotton-weaving and allied processes. Scarlet fever and diphtheria were unusually prevalent; the former was of a mild type. This disease showed itself in severe form and accounted for 18 deaths, a case-mortality rate of 10·1 per cent. Of the fatal cases, none had received antitoxin before the third day of the disease. An immunisation clinic was opened in November. The Schick test is not being used for children up to the age of 7 years. There were 34 cases of small-pox, all but one of a mild type, and no deaths. Dr. Ella Mackenzie conducts an antenatal clinic twice weekly, which was attended by 70 more women than in 1928. The midwives sent up 92 cases compared with 77 in the previous year. A course of lectures by well-known obstetricians was given to the midwives in order to stimulate their interest in antenatal work. Dr. Mackenzie's investigation of the 15 maternal deaths showed that 2 were associated with eclampsia, 2 with placenta prævia, 2 with puerperal sepsis, 2 with septic peritonitis (one being after an illegal operation), 3 with pneumonia, and 4 with other conditions. Her investigation of 75 still-births showed that in 33 the cause was unknown and that the principal among the known causes were: breech presentation, 7; difficult forceps, 3; placenta prævia, 5; toxæmia, 9; and "probable" syphilis, 3. The deaths of pre-school children were 70 as compared with 43 in 1928, pneumonia showing the chief increase from 11 to 29. There are now 11 nursery classes in Blackburn with accommodation for 450 children under the age of 5 years. The corporation erected 194 new houses and private enterprise 84, and at the end of the year 194 municipal houses were in course of erection. The inclusive weekly rental is 13*s.* 10*d.* for a non-parlour house with three bedrooms; 11*s.* 11*d.* for one with two bedrooms. The waiting-list for municipal houses of the various types at the end of 1929 was 753. Dr. Thierens says the population is comparatively well-housed and that there are no well-defined slums.

Stockport.

Dr. Nicolas Gebbie tells us that the rivers Goyt and Tame unite at Tiviotdale to form the Mersey, and that the borough is situated on both the Lancashire and Cheshire sides. Near the river stands the old part, around which a large town has grown, the chief occupations of which are cotton-spinning, weaving, and doubling, hat manufacture, &c. The inhabitants are chiefly housed in dwellings of the cottage type, "two up and two down," placed in long rows. There is a serious shortage of houses; the "subsidy" houses, erected in 1929, were 112 municipal and 235 by private enterpris The Municipal Maternity Hospital has accommod tion for 16 mothers and 16 babies; in it 165 wome were delivered by midwives and 60 by doctor Patients not attended by a doctor are examine by Dr. Jean Mackintosh prior to discharge and fo weeks later at the clinic. Dr. Mackintosh al conducts the four antenatal clinics which we attended by 863 expectant mothers. The midwiv coöperate well; 60 per cent. of the midwives' cas attended in 1929 compared with 37 per cent. in 192 The orthopædic scheme at Stockport Infirmar associated with the Orthopædic Hospital at Oswestr is utilised by both the tuberculosis and child welfa departments. The provision of additional accon modation at the Isolation Hospital is under consider tion, and another need pointed out by Dr. Gebb is a destructor to reduce the tip nuisance.

Bury.

Dr. G. Granville Buckley speaks of the increasi neglect of vaccination. During 1929 only 12·8 p cent. of the children born were vaccinated. Th high mortality among children of ages 1 to included 9 deaths from pneumonia, 7 from bronchiti 6 from whooping-cough, and 2 from measle The notifications of diphtheria (165) were mo numerous than ever before, but the case-mortalit was only 3 per cent. Bury joins in the count orthopædic scheme and sent 10 pre-school childre to the county clinic, one of whom was admitte to Biddulph Hospital. The V.D. officer, Dr. Holker, says that practitioners use the clinic increa ingly. Since many cases are only sent to him the secondary stage, he infers that some practitione do not realise that spirochætes can be detect in a primary sore before the Wassermann reactic is positive. He points out that smears should taken before treatment and that soft chancres a frequently syphilitic. The sewage of the borou is of a complex nature and includes trade wast from tanneries, fell-mongers, wool scouring, hatter breweries, and gas liquor. Three separate systen follow the sedimentation tanks, including an activat sludge unit. A further extension has been necessitat by the admission of spent ammoniacal liquor fro the gas works. A sludge plant has been install but at present the sludge is disposed of on lagoon Of the last six samples of effluent taken by t inspectors of the Mersey and Irwell joint cor mittee two were satisfactory and four were ba During the year 213 half-hour observations black smoke were taken and four firms exceed the limit of two minutes black smoke per ha hour, the average emission being six and a ha minutes per half hour. Appropriate remedial ste were taken. Bury has had a model public abatto since 1903 (when all the private slaughter-hous were abolished), which could deal with three or fo times the present call upon it.

A MIDDLESEX CONVALESCENT HOME.—Lo Rochdale, Lord-Lieutenant of Middlesex, recently opened convalescent and holiday home for necessitous Middles school-children at Collington Manor, Bexhill. It has be purchased and equipped by the Middlesex King Edward V Memorial Fund.

HOSPITALS FOR THE SCOTTISH ISLES.—The Scotti Department of Health has made a grant of £6000 for t erection and equipment of a Cottage Hospital in Islay; t cost of maintenance will be borne locally. It is understo that the Bute Hospital in South Uist will shortly be de with by the Department.

MANCHESTER BABIES' HOSPITAL.—The report stat that there were 474 admissions and 70 deaths during t past year, a percentage of 14·73. The average stay of cases was 60·50 days, and of fatal cases 27·48 days—18 cas died within 48 hours of admission. The out-patien department has passed the experimental stage and is n firmly established, 644 cases having been treated during t first year.

SCHOOL MEDICAL SERVICE.

—	No. on roll.	Average attend-ance.	Routine inspec-tion.	Special exams. and reinspec-tions.	Percentage of defects.
Leeds	73,613	—	20,384	68,990	35·7
Gillingham ..	8,137	7,299	2,846	2,279	16
Eastbourne..	4,928	4,391	1,653	6,803	10·7

Leeds.

On the subject of malnutrition, Dr. Algernon Wear truly remarks that "many of these children are in need of a good midday meal and more sleep." His assistants, Dr. Stockwell and Dr. Wood, point out that "the open-air school as a method of treatment (including correct feeding and malt and oil) is incomparably ahead of anything we do or can hope to do by the artificial sunlight treatment," and it is satisfactory to note that plans have already been prepared for an open-air school at which the children will have the benefit of good diet, rest, fresh air, sunlight, and other favourable influences.

An interesting experiment on the effect of extra milk is described. A comprehensive scheme was undertaken in coöperation with the medical officer of health (who controlled the quality and purity of the milk), the Dairymen's Association, the National Farmer's Union, and the head teachers. The number of children to whom extra milk was given averaged over 20,000, their parents paying 1*d.* a day. At the time of writing the scheme has been in operation for only three months, but comparisons with other children show that except for boys of 7 and 11 the average weight of those receiving the milk is substantially above the average for the city.

Children taking part in public entertainments are exposed to many adverse influences, and at the medical examination it was found that many of them were below the average standard of health and suffering from overstrain. "It would appear," says Dr. Wear, "that for such a strenuous life only the exceptional physical type should be certificated," but in practice, of course, these children are often of a type which is unusually susceptible to nerve strain. Mr. Capes, the inspector for employment of children, in his appended report questions whether the minimum age for their certificate should not be raised to 14 and whether the latest hours allowed should not be 9 P.M. All these suggestions are worthy of careful consideration, and in our opinion it would be well if all authorities who license theatrical children realised their responsibilities and maintained a uniform standard.

The authorities in Leeds are to be congratulated on maintaining a nursery school and also on the attention that is being called to the needs of stammerers. It may appear contradictory to the ideals of progress that a decrease in the number of attendances at the treatment clinics should be welcomed, but it is explained that it has been felt for some time that children were forming a "clinic habit," because they enjoyed the change from lessons. This year the attendances have been kept down by stricter observation, especially of trivial complaints, and at one clinic minor ailments are to be dealt with at 4 P.M. in order to thwart the juvenile ingenuity.

Gillingham.

Comparisons are proverbially undesirable, but it is impossible to ignore the fact that there are several towns smaller than Gillingham which have made more complete arrangements for the treatment of defects and for the care and education of exceptional children, though the efficiency of the medical officers is evident. Some orthopædic cases attend St. Bartholomew's Hospital, Rochester, but there is no orthopædic scheme. There are no systematic in-patient arrangements for dealing with tonsils and adenoids; patients remain for some hours after operation and are re-examined by the house surgeon, and may be kept in overnight if there are exceptional features. Those sent home travel by the corporation ambulance. The dental scheme is not complete enough to allow of the re-examination of every child annually, but this ideal is attained only by a comparatively few very progressive towns; at Gillingham the dentist's sessions have been increased from three to five a week, so that it was possible to examine all children from 6 to 10 years old. The anæsthetist for dental work is Dr. Meta Dunlop, who acts also as part-time assistant school medical officer. Here, again, Dr. W. A. Muir, who acts both as medical officer of health and school medical officer, is at a disadvantage compared with many of his colleagues, for Dr. Dunlop devotes to school inspections only seven sessions a fortnight. With the inclusion of the parish of Rainham and other demands on his time it is clear that Dr. Muir will need more help.

No nursery school has been established in the borough nor are there special schools of any kind; the need for an open-air school appears particularly urgent. Eighteen exceptional children are, however, maintained by the education committee in various special schools outside Gillingham, and though there is no special school for mental defectives there is an active branch of the Kent County Association for Mental Welfare which successfully maintains an occupation centre.

The number of cases of malnutrition recorded at medical inspections is only six, but nearly 200 children were having free dinners last year. In July, 1929, Dr. Muir suggested to the committee that instead of this free dinner a pint of milk should be given daily, the cases being recommended by school medical officers on medical grounds and by head teachers on financial grounds. Shortly after this scheme began a number of other parents asked for their children to have milk, stating that they were willing to pay for it. Special care was taken to obtain the best milk in good condition, and the scheme, which came into operation on Nov. 4th, promises very well.

Though the facilities at Gillingham are not at present extensive it is evident that the medical inspectors are held in high regard, for the proportion of parents attending inspections was 80 per cent. at all ages and 94 per cent. for entrants.

Eastbourne.

Eastbourne is exceptional in the small proportion of children to the general population. The percentage fell from 21·19 in 1891 to 16·4 in 1921, and is still falling. Yet in some quarters more accommodation is needed because through the housing schemes some families have moved from the centre to the border of the borough. The percentage of attendances (89·1) is good and shows the careful activity of the school attendance officers. In view of the small numbers, the arrangements for the treatment of defects are very satisfactory, and there are nine varieties of clinic in the borough. There is also an open-air school which is giving good results. Dr. E. H. B. Coghill, the assistant school medical officer, says that the children admitted to this school, although classified into those suffering from anæmia, debility, malnutrition, and outgrowing strength, show in fact a very similar picture in each case, and that the accompanying report from the old school is almost invariably the same, the comment being "listless," "easily fatigued," "poor concentration," "poor progress in school work generally." The average period during which the children remained at the school was 25 months, and in no case during the year was it found necessary to readmit a child previously discharged as cured. These results are attributed largely to the keen interest taken in the medical side of the work of the headmistress, Miss Martin, and her staff. The arrangements for exceptional children are also good.

Among other activities noted by Dr. W. G. Willoughby in his report are: (1) the supply of milk to 364 children, due to the enterprise of the head teachers; (2) health propaganda by the

issue of 2000 copies each month of a monthly journal *Better Health* through the schools; (3) school camps held in July; (4) physical training organised by Captain Stainfield; (5) in secondary schools flat-foot and slight degrees of spinal curvature have been improved by exercises, and in the girls' school foot troubles are less frequently complained of since the all-day use of "plimsols" has been vetoed and house shoes with low heels have been substituted.

MENTAL HOSPITAL REPORTS.

THERE were 675 patients on the books of the CITY OF LONDON MENTAL HOSPITAL at STONE on the last day of last year. During the year 121 certificated and 100 voluntary patients were admitted. The recovery-rate of the patients under certificate was 44 per cent. of the direct admissions, and their death-rate 7·8 per cent., while 40 per cent. of the voluntary patients left the hospital recovered or relieved. There was very little illness during the year. General paralysis has been successfully treated by malaria, and the operating theatre, X ray room, dental surgery, and laboratory have all been in constant use. Parole beyond the estate was allowed to 58 men and 24 women, and within the grounds to 88 men and 137 women. Two male and three female wards are administered on the open-door principle. Three nurses and three attendants obtained their R.M.P.A. certificates, two of them with distinction.

The BRIGHTON COUNTY BOROUGH MENTAL HOSPITAL had 875 patients in residence on Dec. 31st last. The recovery-rate for the year was 42·2 per cent. and the death-rate 10·1 per cent. Five general paralytics received malarial treatment at Hellingly and one has been discharged. On an average there have been 18 male patients and 39 females on full parole, and an additional 53 men on parole within the grounds. A number of patients have had week-end leave. Some difference of opinion has arisen in the committee as to the best site for the proposed admission hospital, but it is hoped to proceed with the building before long. A new cricket pitch has been made in the park. The dental surgeon attended 750 patients during the year. Since the out-patient clinic opened at Brighton in January, 1926, 371 patients have attended; there were 90 new cases during 1929. Three patients have been certified under the Mental Deficiency Act, but none at all under the Lunacy Act. Not one of the 200 patients admitted to the mental hospital during the year from Brighton had attended the out-patient clinic.

Of the two mental hospitals under the ESSEX AND COLCHESTER COMMITTEE, that at BRENTWOOD had 1774 patients under care at the end of last year. The death-rate was 6·22 per cent., the lowest on record for this institution, despite the fact that 16 patients died of general paralysis and 15 of cardio-vascular degeneration. Post-mortem examinations were made in 81 per cent. of cases. The general health was very good and there were no epidemics. General paralysis has been treated by malaria with encouraging results, and other methods of producing fever are being tried. The visiting surgeon has performed several urgent operations and the dentist has attended twice a week. The dispenser is also an optician, and has done a good deal of sight-testing. For the first time the home dairy herd has supplied all the milk required, some 620 quarts daily, and nearly all new patients show a marked gain in weight. The hospital has for some time been overcrowded, and the opening of the new nurses' home will give some relief, as well as enabling the staff to spend off-duty hours away from the wards. Ten men and 16 women obtained their R.M.P.A. certificate during the year, three of the men with distinction. Electricity is now available throughout the hospital and is proving a great boon. A general purposes machine has been set up in the kitchen and a refrigerating plant is to be installed. New clinical rooms have been equipped in the male infirmary and admission wards. The weaving and handicraft department keeps many patients usefully occupied. Three female and five male wards are open, and parole and week-end leave are freely granted. Patients are clothed in dresses of different colours and style and the more responsible ones are allowed to choose the fashion of their clothes.

The hospital at SEVERALLS had 1819 patients in residence at the end of the year. The death-rate was 9·24 per cent., and the general health was satisfactory except for a few cases of colitis during the autumn. The recovery-rate was 25·8 per cent. Occupational and ultra-violet light therapy are giving very satisfactory results. The open-air treatment of acute cases has proved an unqualified success and the new canteen promises to be most useful. A pathological laboratory has been completed and will soon be in use, but the X ray plant is nearly obsolete and needs replacing. Three male and two female wards are open to the grounds and four other wards to gardens. Parole and leave are given as far as possible. The nursing staff are prepared for examination, and 92 men and 46 women have now passed their final.

On the first day of this year there were 714 patients at the LEICESTERSHIRE AND RUTLAND MENTAL HOSPITAL, NARBOROUGH. The recovery-rate for the year was 40·88 per cent. and the death-rate 8·22 per cent. One ward on either side is administered on the open-door principle; 12 men have full parole and 40 have parole within the grounds. Nearly 6000 articles of clothing were made in the hospital during the year, and the tailors' and shoemakers' shops were also kept busy.

The EAST RIDING MENTAL HOSPITAL at BEVERLEY housed 603 patients on March 31st of this year. The recovery-rate was 38 per cent. and the death-rate 10·68 per cent. Autopsies were performed whenever permission was granted—i.e., in 83 per cent. Hydrotherapy has given very satisfactory results in acute cases, and a continuous bath is to be installed in the female admission ward. Encouraging results have been obtained from the use of tryparsamide in neurosyphilitic cases and malarial therapy is used for cases which do not respond to tryparsamide. Forty patients are allowed parole outside the estate, and 12 within the grounds; the men greatly enjoy the local race meetings. A cinema has been installed. Arrangements have been made to accommodate mentally defective children elsewhere; this will relieve congestion in the hospital and be better both for the children and for the hospital patients. A consulting surgeon has been appointed. The dentist paid 26 visits during the year and examines all new patients systematically. There is a shortage of female nurses, but 54 per cent. of the men and 17 per cent. of the women hold the R.M.P.A. certificate.

The GLAMORGAN COUNTY MENTAL HOSPITAL at BRIDGEND had 2030 patients on the register at the end of last year, and overcrowding is acutely felt. The recovery-rate was 27 per cent. and nearly all recovered patients showed an increase of several pounds in weight. The death-rate was 8·2 per cent. The general health was good, except for an influenza epidemic, four cases of dysentery, and one of erysipelas. The visiting surgeon performed an operation for appendicitis and 300 patients received dental treatment. Plans are in hand for the erection of an admission hospital, convalescent home, and nurses' home. The inmates are employed as far as possible, but there is no occupations officer. Full parole is allowed to 9 men and limited freedom to 90, but no women have this privilege. The death-rate from tuberculosis is higher than the average of mental hospitals—viz., 10·1 per cent.—and modern methods for treating general paralysis are not yet in use. Of the 25 candidates, 10 men and 5 women obtained their R.M.P.A. certificate during the year.

The JOINT COUNTIES' MENTAL HOSPITAL at CARMARTHEN housed 659 patients on March 31st last.

The recovery-rate was 35·2 per cent., and 91 per cent. of the patients who completely recovered were in residence for less than a year. The death-rate was 10·62 per cent. and the general health was unsatisfactory. There was influenza in the spring, 13 cases of diarrhœa, 4 of dysentery, 3 of enteric, and 8 of tuberculosis. Two surgical cases were sent to the infirmary for treatment. The dentist saw 158 patients. A new water-supply has been completed. Patients are being instructed in rug making and an attempt is to be made to expand the scheme of industries. Parole is allowed to 4 men outside and 84 inside the estate, but not to any women, and only 10 patients were allowed out on trial. Four nurses passed the final examination for the R.M.P.A. certificate.

PRIVATE INSTITUTIONS.

The JAMES MURRAY'S ROYAL ASYLUM, PERTH, presents its 103rd report this year. There were 192 patients on the register on April 1st last, but owing to lack of accommodation a number of applications for admission had to be refused. A new reception hospital is being built at Gilgal and will be available, it is hoped, before the winter. During the year 24 certified and 57 voluntary patients were admitted. Seventeen certified and 20 voluntary patients were discharged recovered, and 9 voluntary patients were certified. The death-rate was 12·43 per cent. and post-mortem examinations were made in 8 of the 22 cases. The institution had the misfortune to suffer from a fire on April 19th. The damage has been assessed at £2400, but would have been greater had not the wing been rebuilt in 1837 with fire-proof arches. The routine of the institution was maintained remarkably well. Five nurses and four attendants obtained their R.M.P.A. certificate during the year.

At BARNWOOD HOUSE, near GLOUCESTER, there were 141 patients at the end of last year, and also 18 voluntary boarders. There is a great demand for admission to the Manor House, where voluntary boarders are received. The recovery-rate was 32·5 per cent. and the death-rate 7 per cent. There was an epidemic of influenza in the spring, but otherwise the health was good. A patient suffering from taboparesis improved under malarial treatment, and three cases of confusional insanity were found to be suffering from an unusual type of intestinal toxæmia. The visiting pathologist and the dentist have both extended their work, and an ultra-violet ray lamp has been purchased. The electrification of the hospital was completed during the year and a cinema and a refrigerator have been provided. Arts and crafts are taught to the ladies during the winter, and a seaside house is taken for the summer. In the competition of the Gloucestershire Milk Recording Society the institution obtained the Cadbury Cup and Gold Medal for clean milk. Another nurse obtained her certificate, bringing the total certified or registered to 21 men and 18 women

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED AUGUST 2ND, 1930.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 70 (last week 109); scarlet fever, 1778; diphtheria, 1108; enteric fever, 92; pneumonia, 431; puerperal fever, 46; puerperal pyrexia, 111; cerebro-spinal fever, 4; acute poliomyelitis, 13; acute polio-encephalitis, 6; encephalitis lethargica, 13; continued fever, 1; dysentery, 22; ophthalmia neonatorum, 111. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on August 5th–6th was as follows: small-pox, 218 under treatment, 10 under observation; scarlet fever, 1779; diphtheria, 2007; enteric fever, 38; measles, 219; whooping-cough, 83; puerperal fever, 15 (plus 8 babies); encephalitis lethargica, 119; "other diseases," 20. At St. Margaret's Hospital there were 14 babies with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox or enteric fever, 13 (1) from measles, 7 (3) from scarlet fever, 18 (0) from whooping-cough, 35 (17) from diphtheria, 37 (7) from diarrhœa and enteritis under two years, and 12 (0) from influenza. The figures in parentheses are those for London itself.

No great town reported more than 1 death from measles with the exception of Liverpool with 2. Liverpool also reported 4 deaths from whooping-cough, Bristol and Leeds each 2. Four deaths from diarrhœa were reported from West Ham, 2 each from Willesden, Portsmouth, Leicester, Derby, Liverpool, Manchester, Rochdale, Leeds, and Sunderland.

The number of stillbirths notified during the week was 265 (corresponding to a rate of 37 per 1000 births), including 45 in London.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE.

Surg. Capt. L. Warren to *Pembroke*, for R.N. Hospital, Chatham.

Surg. Comdr. G. S. Harvey to *Pembroke*, for R.N. Hospital, Gt. Yarmouth.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Sub-Lts. W. J. Poole and V. S. Hughes-Davies to be Surg. Lts.

Proby. Surg.-Lts. G. M. Tanner and A. D. Hepburn to be Surg.-Lts.

Proby. Surg.-Lts. (D) to be Surg.-Lts. (D): F. A. Pearse, A. W. Y. Price, and R. W. Stevens.

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. E. G. Anthonisz, Reg. Army Res. of Off., to be Maj., whilst re-empld. under Art. 507 (b), Royal Warrant for Pay and Promotion, 1926, and relinquishes the rank of Lt.-Col.

Maj. A. D. O'Carroll retires on ret. pay, and is granted the rank of Lt.-Col.

Maj. D. T. Richardson to be an Asst. Professor at the R.A.M. Coll.

Maj. (now Lt.-Col.) A. Dawson to be an Asst. Professor at the R.A.M. Coll.

ARMY DENTAL CORPS.

The undermentioned Capts. to be Majs.: G. A. G. Jones, E. H. C. Caute, C. V. Walker, M. J. O'Reilly and T. Pearson.

Lt.-Col. & Bt. Col. J. A. Seymour, having attained the age for compulsory retirement, is placed on retd. pay.

Maj. J. V. M. Byrne to be Lt.-Col., vice Lt.-Col. & Bt. Col. J. A. Seymour.

Lt. P. M. Margand, Dental Surg., relinquishes his temp. commn. on appt. to a non-permanent commn. in the R.A.F.

RESERVE OF OFFICERS.

Maj. A. H. Hayes, having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

TERRITORIAL ARMY.

Lt.-Col. D. S. Sutherland to comd. 12th (2nd Western) Gen. Hosp.

Capt. F. B. Chavasse resigns his commn. and retains his rank, with permission to wear the prescribed uniform.

Capt. S. Orchard resigns his commn.

J. F. Wilde (late Temp. Capt., R.A.M.C.) to be Capt. with seniority.

Lt. W. R. Nash (late R.G.A., Spec. Res.) to be Lt.

J. W. Graham to be Lt.

The King has conferred the Territorial Decoration upon Capt. K. B. Dickson.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Lt.-Col. J. Ramsay, from Active List, to be Lt.-Col.

Maj. H. J. Dunbar, having attained the age-limit, retires and retains his rank, with permission to wear the prescribed uniform.

Lt. T. A. A. Hunter, from Active List (Supern. for serv. with O.T.C.), to be Lt.

ROYAL AIR FORCE.

Flight Lt. A. F. Cook ceases to be seconded for duty with the Trans-Jordan Frontier Force.

Denal Branch.—The undermentioned Flight Lieutenants (Temp. Captains, General List, Army Dental Surgeons)

are granted non-permanent commissions as Flight Lieutenants: J. M. Jamie and H. D. Humphreys.

INDIAN MEDICAL SERVICE.

Lt.-Col. H. R. Nutt to be Col.

The undermentioned officers retire: Lt.-Cols. D. McN. Taylor, D. Heron, and G. I. Davys.

COLONIAL MEDICAL SERVICES.

Dr. J. W. P. Harkness, Senior Medical Officer, Palestine, and Dr. N. M. Maclennan, Health Officer, Kenya, have been promoted Deputy Director and Senior Medical Officer respectively, to the Department of Health, Palestine.

The following appointments have been made: Miss F. A. Adam, Lady Medical Officer, Gold Coast; and Dr. P. F. S. Court, Dr. G. V. A. Griffith, and Dr. J. B. Mackie, Medical Officers, Hong-Kong; Dr. P. J. Bourke has been appointed a Medical Officer in the West African Medical Service, and Dr. A. Cathcart, Medical Officer at Sierra Leone, West African Medical Staff.

DEATHS IN THE SERVICES.

Surg.-Capt. Douglas Duke Turner, R.N., retired, who died at the age of 53 in the Royal Naval Hospital, Haslar, on August 4th, qualified with the conjoint diploma in 1900 and entered the Naval Service in 1904. He was promoted to staff surgeon some eight years later, and was medical officer to the cruisers *Sappho* and *Devonshire*, and after his promotion to Surg. Commander in 1917 he occupied a similar position in the cruiser *Concord*, the battleship *Resolution* and the *Defiance*, torpedo schoolship at Devonport. He retired with the rank of surgeon captain, 1927.

CORRESPONDENCE

UMBILICAL HERNIA IN INFANTS.

To the Editor of THE LANCET.

SIR,—May I be allowed to say a few words about Mr. C. P. G. Wakeley's article on this subject which appears in the "Modern Technique in Treatment" series in your issue of August 9th. Inasmuch as the views expressed in this article are in conflict with what is generally taught and practised in our welfare centres, it is important that both sides of the question should be discussed so that the truth may prevail. Mr. Wakeley claims that the condition is more common now than it was 20 or 30 years ago. This statement is unsupported by statistical evidence, and although I have none to offer, I may state—for what it is worth—that this is quite contrary to my own personal experience. Both in private and in hospital practice I am under the impression that I see far fewer cases of this kind now than I did formerly.

Again, one of the causes assigned by Mr. Wakeley for umbilical hernia is artificial feeding, and he adds that artificial feeding is more generally employed now than 20 or 30 years ago. But is this so? I very much doubt it. Most welfare centres and well-informed medical practitioners now make very successful efforts to popularise breast-feeding, especially during the first few months of life, when the character of the feeding is most likely to affect the issue in question. My general impression is that I see more cases of umbilical hernia among breast-fed infants than among artificially fed infants. This may be because there are more breast-fed infants, or it may be that over-feeding is more likely to occur under uncontrolled breast-feeding than under controlled bottle-feeding.

Another cause of umbilical hernia assigned by Mr. Wakeley is the almost universal abandonment of the binder, and he gives it as his opinion that it is of the greatest importance that infants should wear abdominal binders until at least six months old. If this advice, he says, were followed, "there would be far fewer cases of infantile umbilical hernia attending our hospitals." For my part, I think that if this practice were adopted there would be a larger number of infants attending our hospitals for digestive and other abdominal troubles. I have seen several cases of inguinal hernia brought about by the use of the tight circular binder employed to control umbilical hernia—a very natural consequence owing to the rise in abdominal pressure to which such treatment would tend.

Mr. Wakeley gives very full particulars of the operation he advocates for umbilical hernia. In the whole of my experience I have never found it necessary to resort to operative treatment for this condition. The very simplest precautions will prevent the development of umbilical hernia, and the common-sense use of a little strapping properly applied, but not quite in the manner described in the article referred to, will cure the condition. I am told that quite a large number of Zulu infants, the majority of whom are breast-fed, as well as many other South African native infants suffer from umbilical hernia, but that the condition is never found amongst the adult population, for the reason that spontaneous cure always occurs when the recti muscles become adequately developed—a result which the binder would certainly delay.

Although at the present time I have no statistical evidence on the points raised, I understand from Dr. Jean Smith, the registrar at the Infants Hospital, that she will try to produce some with respect to the relative frequency of umbilical hernia amongst breast-fed and artificially fed infants, and also with respect to the frequency of the condition among all classes of infants attending the hospital.

I am, Sir, yours faithfully,

ERIC PRITCHARD.

Harley-street, W., August 9th, 1930.

TREATMENT OF PULMONARY TUBERCULOSIS IN SWITZERLAND.

To the Editor of THE LANCET.

SIR,—Dr. Harrison's general proposition, that rest and prescribed exercise occupy a more important place in the treatment of pulmonary tuberculosis than climate, is in conformity with modern views. The point will bear emphasis over and over again, for the majority of patients, sanatorium committees, and even medical practitioners are slow to appreciate its full significance. I cannot, however, agree with Dr. Harrison when, in a sweeping generalisation, he decries the treatment conditions in the high Alps.

Having visited the chief sanatoria of Davos, Arosa, Leysin, and Montana I have been impressed with the cold, dry, windless atmosphere, with brilliant sunshine generally present in these places in winter, and contrasting so favourably with the damp misty conditions which so often prevail in England. Especially at Montana are climatic conditions particularly favourable. There one lives above the clouds, and looks down on the "sea of mist" hundreds of feet below. The sunshine record, I believe, is among the best of all Alpine villages. Most of the patients I saw were British. English was freely spoken. The British sanatorium there was not over-heated like so many which cater for continental patients. The patients were far from being bored by the eternal snow. Many with whom I conversed were watching with amusement the sport on the ice

ink, the toboggan and ski runs, while sitting or trolling in brilliant sunshine. The whole atmosphere was joyful, uplifting, and could be, at the same time, profoundly restful. Compared with it, the average humid winter day in England is gloomy to a degree.

Another point of the greatest importance in favour of the Swiss curing stations is the wealth of specialist medical talent available at each centre. Tuberculosis has been the prime medical interest of the whole coterie of doctors in each centre for many years. There is a vast accumulated experience of the disease. Every advance in treatment is exhaustively discussed and tried out with avidity. While every doctor specialises in tuberculosis, there is, moreover, a specialist for each branch of the subject, be it X ray diagnosis, oleothorax, thoracoplasty, or any known treatment. In this respect each centre may claim to be a complete unit for the treatment of tuberculosis.

Doubtless in some institutions the discipline of routine treatment may not be so rigid as it should be, but, as far as I could judge, this did not apply in Montana, where also the arrangements are particularly well suited to British people.

I am, Sir, yours faithfully,

H. STANLEY BANKS,
Medical Superintendent, Isolation Hospital and Sanatorium, Leicester.

August 11th, 1930.

THE DUTCH PESSARY.

To the Editor of THE LANCET.

SIR,—I am glad that Dr. Helena Wright has called attention to the importance of using a second contraceptive with a Dutch rubber pessary. Where it is important to prevent conception I believe the physician should advise a carefully fitted rubber pessary, lubricated with a contraceptive spermaticide such as Dr. Haire recommends and, in addition, a soluble pellet or pessary containing quinine or other substances of a well-known brand, which must be freshly prepared. I recommend douching next morning before and after the removal of the rubber pessary. I think disappointment has occurred in the past through using pessaries unnecessarily large. My own experience is that the majority of women are best fitted with 50–55, and less commonly 60 mm. Each case has to be judged separately. Women with a well-formed os, where there is no tear, may find the check pessary with the self-retaining rim perfectly satisfactory. In a few instances no form of rubber pessary is of the slightest use; in this case a soluble pellet or pessary and a rubber sheath should be recommended when it is necessary to prevent conception. In my opinion, this last is the most reliable method.—I am, Sir, yours faithfully,

ELIZABETH SLOAN CHESSER, M.D.
Harley-street, W., August 12th, 1930.

MEDICAL NEWS

University of Cambridge.

At a congregation on August 2nd the following degrees were conferred:—

M.D.—H. V. Dicks and G. W. Bamber.

M.B., B.Chir.—*C. I. C. Gill, R. E. Barnsley, and J. D. Simpson.

M.B.—F. A. Richards, E. J. Pye-Smith, R. L. Osmaston, and B. C. Tate.

B.Chir.—*A. C. Crooke, *H. W. Sadlier, R. S. Stacey, B. C. Nicholson, P. G. Levick, V. P. Paxon, I. J. Franklen-Evans, and J. S. S. Fairley.

* By proxy.

Mr. Eric Gordon Holmes, M.A., M.B., B.Chir., has been elected a non-stipendiary Fellow of Downing College. He was formerly a scholar of Christ's College and a student at St. Bartholomew's Hospital. In 1926 he was appointed assistant to the Downing Professor of Medicine, and is engaged in research.

St. Bartholomew's Hospital and College.

The Old Students' annual dinner will be held in the great hall of the hospital at 7 P.M., on Wednesday, Oct 1st, with Mr. L. B. Rawling in the chair.

Tour of Medical Italy.

The annual medical tour to spas and other health resorts in Italy, organised by the Italian State Tourist Department, will take place from Sept. 10th to 26th. Among the places to be visited are Merano, Carezza (Karersee), and other Dolomite resorts, Riva and Gardone on Lake Garda, Montecatini and Viareggio. An English-speaking Italian doctor accompanies the party. Full information from the Italian Travel Bureau, 16, Waterloo-place, London, S.W.1.

The late Mr. J. T. Ainslie Walker, F.I.C., F.C.S.

The sudden death occurred of Mr. J. T. Ainslie Walker on July 27th. He was educated at Watson's Boys' College and at Edinburgh University, where he studied mainly chemistry. His researches into the values of disinfectants and antiseptics, conjointly with the late Samuel Rideal, resulted in the Rideal-Walker coefficient test for standardising bactericidal powers. During the war he was in charge of a mobile laboratory, and gave special attention to the outbreaks of dysentery which occurred from time to time, and to the treatment of the disease by intestinal antiseptics. The outcome of this work was the introduction to the medical profession in 1922 of the benzene derivative which he christened dimol. He gained a commission with the rank of Captain in the war, and was one of the few non-medical members of the Royal Society of Medicine.

North Staffordshire Royal Infirmary.

Sir Harold Gillies recently opened two operating theatres at this institution, one of which, the joint gift of Mrs. Montford and Mr. Henry J. Johnson, is entirely new, while the other has been reconstructed. The need is indicated by the fact that last year there were 3512 operations upon in-patients, and a total of nearly 13,000 minor operations.

Arundel Hospital.

Sir William Bird, J.P., presiding at a meeting of the governors, announced the gift of £5000 from Miss K. Mitchell for the erection of a new hospital. An appeal has been launched for the raising of the balance required—£2000. The new institution is to be a cottage hospital on a pavilion plan, and will be erected on a site given by the Duke of Norfolk on the Arundel-Chichester road.

Royal Microscopical Society.

This Society, whose headquarters were in Hanover-square, London, for some 40 years, has now moved to the B.M.A. House, Tavistock-square, London, W.C. 1, where its library and slide collections will be more adequately housed, and where a portion of its unique collection of historical instruments will be on permanent exhibition. The ordinary meetings will be held as hitherto on the third Wednesday in each month from October to May inclusive in the Hastings Hall, and by the almost unanimous vote of the Fellows these meetings will be held at 5.30 P.M. instead of at 8 P.M. as formerly. Sectional meetings will be held in the Pillar Hall.

Reunion of the Romance Medical Press.

The second annual gathering of the Federation of the Presse Médicale Latine will be held at Brussels from Sept. 28th–30th, during the centenary commemoration of Belgian independence. The reunion will have the patronage of the Minister of Science and Art and will be presided over by Prof. Maurice Loeper and Dr. Albert Delcourt, presidents respectively of the French and Belgian associations. On the first day of meeting Prof. Emile Forgue, of Montpellier, will open a discussion on the Contemporary Medical Journal and Medical Journalist, the afternoon being given up to considerations of finance and transport. On the second day three interesting topics come up for discussion: (1) the rights of editors of periodicals, (2) the issue of a dictionary of medical terms, and (3) the rôle of the medical press in the diffusion of large scientific and professional ideas. On the third day the delegates will make a comprehensive tour including the Antwerp Exhibition. The general secretary of the congress is Dr. René Beckers, who may be addressed at 36, Rue Archimède, Brussels.

Enlargement of Carshalton Hospital.

The Carshalton, Wallington, and Beddington War Memorial Hospital has been enlarged by the addition of a women's ward of 14 beds, an isolation ward, two children's wards, and 15 private wards. The hospital now contains about 60 beds. A nurses' home is being given by Major Mallinson, at a cost of £5000.

Coombe Lying-in Hospital.

The clinical report of this Dublin hospital for 1929 makes the familiar remark that some of the deaths could have been prevented by efficient antenatal care; nevertheless the morbidity-rate was "reasonably low"—3·8 per cent. The attendance at the prenatal clinics is rapidly increasing, but the "emergencies" far outnumbered the booked cases.

Donations and Bequests.

Mrs. Mary Ann Major, West Cliffe-road, Bournemouth, widow of Herbert Coddington Major, M.D., left £1000 to the Royal Medical Benevolent Fund, £500 each to the West Riding Medical Charitable Society, the Royal Infirmary for the Blind, Frisinghall, the Distressed Gentlefolks' Aid Society, £200 to the Bedford County Hospital, £100 to the Home for Infirm and Aged Women (Jersey), and £100 each to the Jersey Female Orphan Home and the Jersey Society for the Blind.—Among other bequests the late Mr. Joseph Sawyer, of Kenley, Surrey, left £1000 to the Purley Cottage Hospital.

Royal Northern Group of Hospitals.

In addition to the Royal Northern Hospital at Holloway, this group comprises the Royal Chest Hospital, City-road, the Grovelands Hospital, New Southgate, and the Reckitt Convalescent Home at Southend-on-Sea. At the Royal Northern Hospital and its branches, 5752 new in-patients were treated, and the new out-patients numbered 54,196. The enlargement and reconstruction of the out-patients' department is a pressing need. At the Chest Hospital 604 in-patients were treated, and there were 34,579 out-patients' attendances. At the Grovelands Hospital 1315 patients were treated, and at the Reckitt Convalescent Home 637. Since the establishment of the Contributors' Certificate Fund, in 1921, it has collected over £38,000. The general debt of the hospital is now £97,331. The new private hospital for 65 paying patients will cost £57,000 of which £35,000 has been given, and £15,000 lent by Sir Howell J. Williams.

King Edward VII. Welsh National Memorial Association.

At the annual meeting of the Board of Governors held at Carmarthen the President, Mr. David Davies, said that there had been a net decrease of 61 in the number of deaths from tuberculosis in Wales and Monmouthshire, the decrease being most marked in Glamorgan, Monmouthshire, and Carnarvonshire. A high percentage of cases—roughly half—of those referred to the Association were found to be non-tuberculous. Increasing use was made, both in pulmonary and surgical cases, of the trained specialists and equipment provided by the Association. Prof. Lyle Cummins had expressed the view that, in the fight against tuberculosis, the most favourable field for further progress lay in the period of childhood and adolescence, and Dr. R. J. Matthews had confirmed the fact that the critical years in tuberculosis are those of adolescence. This conclusion emphasised even more strongly the importance of the educational campaign in elementary schools.

A Friendly Society Congress.

The ninety-fifth annual high court of the Ancient Order of Foresters, which brought some 800 delegates to Greenock last week, was addressed by Mr. W. Adamson, Secretary of State for Scotland, who said that he was watching the increasing expenditure on sickness and disablement claims with great anxiety. While legislation might be required to bring schemes of social insurance into a complete whole, yet even now much could be done, he thought, by whole-hearted coöperation between all engaged in the service. Mr. A. Marsden, in his address as High Chief Ranger, spoke with satisfaction of a surplus of £1,750,000 in the voluntary section and one of £2,750,000 on the State side. The position of panel doctors had, he said, been made more difficult by the reduction in the interval necessary for removal from one panel to another, and he believed the present procedure placed an undue strain upon the conscientious doctor. Mr. Marsden mentioned two features which in his opinion had won for the insurance principle the confidence of the insured population: (1) freedom to manage their own health insurance affairs by themselves or their representatives, and (2) in the case of friendly societies, liberty to deal with their own brethren in times of sickness and need. The court rejected the proposal that surpluses should be pooled and refused to urge the Minister of Health to make ophthalmic and dental treatment statutory benefits.

Adult Orthopædic Patients.

Adult patients are now being admitted to the Derbyshir County Council's Orthopædic Hospital at Bretby, whic has hitherto been used for children only. A single-store building has been added containing 32 beds, divided equall between men and women. The hospital will continue t specialise in cases of surgical tuberculosis.

Central Hospital for Durham.

The Durham county council has approved a scheme fo the erection of a central hospital to serve the whole of th administrative county. Two adjoining estates, extendin to 62 acres, on the northern boundary of Durham City, ar to be purchased at a cost of £22,000. It is officially state that "practically all the old poor-law hospitals are inadequat and out of date."

Sussex Provident Scheme.

The list of amounts paid to local hospitals in connexio with this scheme for services rendered to subscribers durin the first six months of this year marks a total of £7410 2*s.* 9*d.* or £1361 17*s.* 7*d.* more than for the correspondin half-year of 1929. The Royal Sussex County Hospita received £2992; Royal Alexandra Hospital for Sick Children £873; New Sussex Hospital for Women and Children £709; Hayward's Heath Hospital, £457; Hove Hospital £404; Sussex Maternity and Women's Hospital, £307 Sussex Eye Hospital, £201. Among other payments mad to coöperating institutions and agencies was the sum o £276 to the Brighton Corporation. The Queen's Nurse are in the list for the first time.

Fellowship of Medicine and Post-Graduate Medica Association.

There are two weeks remaining of the special cours arranged by the Fellowship of Medicine at the All Saints Hospital in Genito-Urinary Diseases. Instruction consist of clinical cystoscopic demonstrations on men and women From Sept. 1st to Sept. 13th the staff at the Queen's Hospital Hackney, will provide an all-day course in diseases o children, where a variety of cases will be shown. The annual revision course at the Westminster Hospital will b held from Sept. 15th to Sept. 27th. Teaching will b given in all departments of the hospital. Courses arranged for October include those on diseases of the throat, nose and ear, diseases of children, gynæcology, tropical medicine orthopædics, and a general course (revision), also evening courses for the M.R.C.P. and the Final F.R.C.S. examinations Post-graduates are invited to apply to the Fellowship o Medicine, 1, Wimpole-street, London, W. 1., for particulars of the winter programme, the list of 1931 special courses and the "general course" provided by the associated hospitals.

School Hygiene in Ireland.

At the Trade Union Congress held in Sligo recently a lively discussion took place on the condition of the primary schools as affecting the health of the children. Mr. Frisby, of the National Teachers' Organisation proposed a resolution calling on the Government to make a radical improvement in the conditions of the school buildings and to provide for their sanitation and upkeep. He said that in every county one could see schools which were ill-built and insanitary, a menace to the health of both children and teachers. There could be no effective education in such schools. Senator Cummins drew attention to the fact that the School Meals Act only applied to urban areas, and said that in country districts children who came long distances often had to go hungry all day. The listlessness due to long fasts made it difficult for such children to learn. It is not easy to understand why the School Meals Act is limited to urban areas, as the need for it is quite as great in the country. One of the unanimous recommendations of the committee of inquiry on health services was that the Act should be made applicable in rural as well as urban areas.

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, August 18th, to SATURDAY, August 23rd.—ALL SAINTS' HOSPITAL, Vauxhall Bridge-road, S.W. Afternoon and Evening Course of Clinical and Cystoscopic Demonstrations (Male and Female). Two weeks. Further particulars from the Fellowship of Medicine.

Appointments

BRUCE, C. D., M.B., Ch.B. Edin., has been appointed Medical Officer of Perth Prison and Medical Superintendent of the Criminal Lunatic Dept. State Institution for Defectives.

RUSSELL, BEDFORD, B.Chir. Camb., F.R.C.S. Eng., Surgeon in Charge of the Throat Dept., St. Bartholomew's Hospital.

WALKER, G. F., M.D., Ch.B. Leeds, Hon. Physician, Royal Infirmary, Sunderland.

WATSON, R., B.Chir., Camb., L.R.C.P. Lond., M.R.C.S., D.P.H., Assistant Medical Officer and Assistant School Medical Officer, Doncaster.

Vacancies

For further information refer to the advertisement columns.

Bath, Royal United Hospital.—Asst. H.S. At rate of £120.

Bedford County Hospital.—Asst. H.S. £130.

Birkenhead County Borough Infirmary, Tranmere.—Res. Asst. M.O. £350.

Birkenhead General Hospital.—H.P. Also Cas. O. Each at rate of £100.

Birmingham, City of, P.H. Dept., Tuber. Section.—Asst. M.O. £350.

Birmingham, Highbury Hospital, Moseley.—Res. Asst. M.O. £300.

Birmingham, Midland Hospital, Easy Row.—H.S. £200.

Birmingham, Queen's Hospital, Medical School.—Med. Reg. £200.

Blackburn Royal Infirmary.—3rd and 4th H.S.'s. £175 and £150 respectively.

Bradford City, Municipal General Hospital, St. Luke's.—H.P.'s and H.S's. Each at rate of £200.

Carlisle, Cumberland Infirmary.—2nd H.S. Also H.S. to Special Depts. Each at rate of £155.

Cheshire County Council.—Deputy County M.O.H. £1000.

Chesterfield and North Derbyshire Royal Hospital.—H.S. At rate of £100–£175.

Chester Royal Infirmary.—H.P. and H.S. Each £150.

Colchester, Essex County Hospital.—Asst. H.S. and Reg. £120.

Connaught Hospital, Orford Rd., Walthamstow, E.—Sen. Res. H.S. At rate of £150.

Coventry and Warwickshire Hospital.—Res. H.P. Also Res. Cas. O. £160 and £125 respectively.

Croydon County Borough, Public Assistance Dept.—Res. Asst. M.O. for Mayday-road Hospital. £300.

Denbigh, North Wales Sanatorium, Llangwyfan.—3rd Asst. Res. M.O. £250.

Derby, Derbyshire Royal Infirmary.—Ophth. H.S. £150.

Dewsbury, New Dewsbury and District General Infirmary.—Jun. H.S. £150.

Dorchester, Dorset County Hospital.—H.S. £160.

Dudley, Guest Hospital and Eye Infirmary.—Asst. H.S. £160.

Dumfries and Galloway Joint Sanatorium Board.—Asst. Med. Supt. £300.

Durham County Council.—Asst. Welfare M.O. £500.

Edinburgh, Jordanburn Nerve Hospital, Morningside Park.—Asst. Phys. £400.

Evelina Hospital for Children, Southwark, S.E.—H.S. At rate of £120.

General Lying-in Hospital, York-road, Lambeth, S.E.—Res. M.O. At rate of £100.

Gloucester County and City Mental Hospitals.—Jun. Asst. M.O. £350.

Gloucester, Gloucestershire Royal Infirmary and Eye Institution.—H.P. At rate of £150.

Great Yarmouth General Hospital.—Sen. and Jun. H.S.'s. £150 and £140 respectively.

Guy's Hospital, Dental School, London Bridge, S.E.—Teacher of Conservative Dental Surgery. £1000.

Halifax Royal Infirmary.—3rd H.S. £125.

Hertford County Hospital.—H.P. At rate of £150.

Ilford, King George Hospital.—Res. M.O. £200.

Infants Hospital, Vincent-square, Westminster.—Two H.P.'s. Each at rate of £75.

Inverness, Northern Infirmary.—H.P. and Jun. H.S. £100.

Leicester Royal Infirmary.—H.S.'s and Cas. O. Each £125.

Liverpool Eye and Ear Infirmary, Myrtle-street.—Hon. Asst. S. to Ear, Nose, and Throat Dept.

Liverpool Open Air Hospital for Children, Leasowe.—Jun. Res. M.O. £200.

Liverpool, Public Assistance Committee.—District M.O.'s. Each at rate of £250.

Liverpool, Walton Hospital, Mill-road Infirmary, Smithdown-road Institution, and Alder Hey Children's Hospital.—Res. Asst. M.O.'s. Each £200.

Leeds Jewish Herzl-Moser Hospital.—Res. M.O. £100.

London, County of.—Coroner. £1700.

London Female Lock Hospital, 283, Harrow-road, W.—H.S. £150.

London Hospital, E.—Surgical 1st Asst. and Registrar. Also Medical 1st Asst. and Registrar. Each £300.

London Lock Hospital, 91, Dean-street, W.—H.S. At rate of £200. Also Two Surg. Regs. Each £100.

Manchester Joint Committee on Cancer Research.—Asst. in Cancer Research Laboratories. £400–£650.

Manchester Royal Eye Hospital.—Jun. H.S. £120.

Merthyr General Hospital.—Res. H.S. At rate of £150.

Middlesex Hospital, W.—Medical Men interested in Radium Treatment of Malignant Disease.

Miller General Hospital, Greenwich-road, S.E.—Cas. O. £150.

Newcastle-upon-Tyne, Hospital for Sick Children.—Hon. Asst. Surgeon.

Newcastle-upon-Tyne, Royal Victoria Infirmary, Pathological Dept.—Bio-chemist. £450.

Oldham Royal Infirmary.—Two H.S.'s to Special Departments. Each at rate of £175.

Preston and County of Lancaster Royal Infirmary.—Two H.S.'s. Each at rate of £150.

Rochdale Infirmary and Dispensary.—Jun. H.S. £175.

Royal Air Force Medical Service.—M.O.'s.

Royal College of Physicians.—Milroy Lecturer.

St. John's Hospital, Lewisham, S.E.—Res. Cas. O. At rate of £100.

St. Pancras Metropolitan Borough.—Asst. M.O. £500.

Salford, Hope Hospital.—Res. Surg. O. £400.

Sheffield Royal Hospital.—Res. Anæsthetist. At rate of £80.

Shrewsbury, Royal Salop Infirmary.—Res. H.S. At rate of £160.

Southampton, Royal South Hants and Southampton Hospital.—Two Asst. H.S.'s. Each at rate of £180.

South Shields, Ingham Infirmary.—Jun. H.S. £150.

Stafford, Staffordshire General Infirmary.—H.S. and H.P. At rate of £200 and £150 respectively.

Swansea County Borough, Infectious Diseases Hospital.—Res. M.O. £350.

Taunton and Somerset Hospital.—H.P. £100.

Ventnor, Royal National Hospital for Consumption, &c.—Asst. Res. M.O. At rate of £300.

Victoria Hospital for Children, Tite-street, Chelsea, S.W.—H.S. At rate of £100.

Walsall Manor Hospital.—Res. Asst. M.O.'s. £200 and £150 respectively.

Warwick County Mental Hospital, Hatton.—Jun. Asst. M.O. £350.

West London Hospital, Hammersmith-road, W.—H.P., Two H.S.'s., and Res. Anæsthetist. Each at rate of £100.

Wolverhampton Royal Hospital.—Cas. O. and Res. Anæsthetist. At rate of £125.

Births, Marriages, and Deaths

BIRTHS.

CHARTERS.—On May 9th, at Namirembi, Uganda, the wife of A. D. Charters, M.B., B.Ch., of a son.

CORY.—On August 7th, at Guildhall-street, Bury St. Edmunds, the wife of Dr. J. W. E. Cory, of a son.

DOWELL.—On August 2nd, at the Royal Infirmary, Derby, the wife of W. H. Dowell, M.R.C.S., L.R.C.P., of Castle Donington, of a son.

DURRANS.—On August 5th, at Cornelia Hospital, Poole, Dorset, to Margaret Durrans, wife of S. F. Durrans, M.R.C.S., L.R.C.P.—a son.

FITZSIMONS.—At "Tattysallagh," Caerleon, Mon., to Sheila, wife of Dr. J. O'C. Fitzsimons, of Naas, Co. Kildare—a daughter.

MILLS.—On August 10th, the wife of James Denholm Mills, B.M., B.Ch., of Shortlands, Seaford, Sussex, of a son.

THOMSON.—On August 2nd, at Woodland House, Penrith, the wife of Douglas D. C. Thomson, M.R.C.S., L.R.C.P., of a daughter.

MARRIAGES.

GILLESPIE—HOWARD.—On August 9th, at St. Columba's (Church of Scotland), Pont-street, S.W., R. D. Gillespie, M.D., M.R.C.P., to Audrey Margaret Mary, elder daughter of the late C. R. Howard, M.D., O.B.E. (Milit.), Frome, Somerset, and Mrs. Philip F. Howley, London.

DEATHS.

BRAUND.—On August 3rd, Arthur Mather Braund, M.R.C.S., L.R.C.P., of Hillside, Stratton, North Cornwall.

BROOK.—On August 10th, at Pottergate, Lincoln, Lieut.-Colonel Charles Brook, F.R.C.S., R.A.M.C. (T.) (retired), in his 92nd year.

LLOYD.—On August 6th, Frederick George Lloyd, M.R.C.S. Eng., L.R.C.P. Lond., of Oakwood-court, W., aged 65.

REES-THOMAS.—On August 9th, at Cross-street, Basingstoke, William Henry Rees-Thomas, M.D., M.R.C.S., L.R.C.P., aged 60.

THOMSON.—On August 8th, on R.M.M.V. *Alcantara* in South Atlantic, Emmeline Sibyl, wife of F. G. Thomson, M.A., M.D., F.R.C.P., of 28, Circus, Bath. Buried at sea, August 9th.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

INDEX TO "THE LANCET," VOL. I., 1930.

THE Index and Title-page to Vol. I., 1930, which was completed with the issue of June 28th, is now ready. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 7, Adam-street, Adelphi, W.C.2. Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

NOTES, COMMENTS, AND ABSTRACTS

THE AUSTRALIAN CANCER ORGANISATION.

By Arthur Burrows, M.D., M.R.C.P., D.M.R.E.,
RADIUM AND CANCER ADVISOR TO THE COMMONWEALTH GOVERNMENT.

(*Concluded from p. 331.*)

A GENERAL CONFERENCE.

In the beginning of April, 1930, the first annual conference of the cancer organisations in Australia was held at Canberra. This conference, which was well attended and enthusiastic, discussed such subjects as the progress made in the cancer campaigns in the various States, the organisation of the treatment of cancer by special physical and chemical methods and the results obtained thereby, possible avenues of research in respect of cancer, the evaluation of the various methods of treatment of cancer, and the organisation of the national resources against cancer. It was called by the Minister for Health and an official report of its deliberations will appear in due course.

It was the misstatement of some of the facts and figures brought forward at this conference which led to certain erroneous paragraphs in respect of the cure of cancer in Australia being inserted in the Australian and English lay press. The statements as they appeared in the daily press were given a somewhat sensational turn and were not actually in accord with the reports officially presented and discussed at the conference.

RESULTS OF TREATMENT.

The general position is as follows. Until the end of 1929 (a period which, allowing for different dates of starting, averages out at roughly a year of activity for the whole of the Australian centres) over 3000 cases were treated at the newly constituted cancer centres, of which approximately 2500 were treated by radium. One of the hospitals in Australia which became a radium centre already possessed equipment with deep X ray apparatus, and one or two others at the date of the conference were still waiting for delivery. So that, in the case of Melbourne, the numbers of patients treated at the cancer centre did not include those who were treated by deep X rays alone, but the figures are available for the deep X ray cases treated at the Royal Prince Alfred Hospital, Sydney. The number of cases treated at each centre is roughly proportional to the population of each State and about 8 per cent. of the 2500 cases treated were not malignant.

It was not possible to analyse the results obtained from returns of cases treated right up to date, but the figures of the patients treated up to June 30th, 1929, were analysed by me. At the time that these figures were given it was stated definitely that the word "cure" could not be used, and that it was certain that a very considerable proportion of the cases quoted as "well" would recur in due course. The expression "well" that was used is substantially the same as the term "clinical cure" which is often used in America, and means that no symptoms or signs of the disease could be detected at the date on which the returns of the case sheets were made. The analysis of the patients treated by radium was presented simply with the object of giving some idea of how the work was progressing up to date, and represents merely the early work done at the cancer centres, with the exception of Adelaide, which started late.

It has not been possible to produce all at once groups of experienced radium therapists everywhere in Australia, even though a full post-graduate course has been given at the Sydney University, and a considerable amount of individual instruction t the various State centres and sub-centres. Wh the work which is set forth in the following table w carried out, some of the medical men were ju emerging from the student stage of radium wo

* These glands are chiefly advanced secondary glands occurri after the primary growth had been removed by surgery at so earlier date.

The work is steadily improving and is better the present time than it was at the period which th table covers. It, however, still leaves something be desired and efforts are being made in all directio to ensure improvement.

COMMENT ON THE RESULTS.

The results in the treatment of carcinoma of t tongue and buccal cavity are disappointing, but it h not been possible to indicate the considerable numb of cases in which the primary growth disappear under radium treatment. The majority of the cas which did not improve were unsatisfactory owing t the development of secondary glands.

In Australia, as apparently in England, the idea burying radium needles is the thing which has appeale most to the general medical imagination and it h been difficult, possibly because it needs more technic knowledge, to induce the centres to develop to th extent necessary the application of radium from th surface. Certainly our results from the treatment secondary glands show quite well, when the cas sheets are examined, that the burying of radiu needles in secondary squamous-celled cancer gland in the neck is almost useless. Carcinoma of the ski also shows considerable scope for improvement, bu it must be remembered that, in the first instanc through the necessity of circumstances, many advance cases were treated, as well as patients who ha previously received radiation treatment which ha rendered them radio-resistant.

The obligation of attempting to cure all cases in on treatment and with it the correlated duty of providin only the very best treatment for every cancer cas in the first instance is steadily being taught an inculcated into the minds of the medical practitioner carrying on the radium work.

Carcinoma of the cervix shows 25 per cent. o immediate apparently perfect results. This relativel low figure probably arises from the fact that in number of instances it has been difficult to restrai the inexperienced radiotherapist from changin

pidly from one technique to another instead of rrying out one method thoroughly. Efforts are ing made to straighten out this difficulty, and to ve an example of what can be done even now; at isbane General Hospital, where a very considerable mber of cases of carcinoma of the cervix were ated and one technique was almost constantly plied, 50 per cent. of the cases treated showed no gns or symptoms of the disease after nine or more nths—that is, up till April, 1930.

The total number of cases which showed no signs symptoms of malignant disease nine or slightly re months after radium treatment, excluding dent ulcer, was 123. This represents nearly one-arter of the patients treated. How many of these ses will remain permanently well time alone will w, but it is certain that a proportion of them will e on without recurrence.

Deep X ray treatment has also given some very tifying results, which is all the more pleasing king to the fact that this work was started and rried on in Australia despite a considerable spondency and often opposition.

An attempt is being made to have microscopic amination made of every tumour examined. ing to deficient facilities in one or two centres s has not been done as completely as desired, but hin a month or two it will be possible for every tre to examine every case histologically. So half the cases have had microscopic examinations de although, as has above been indicated, this is t as high a proportion as will shortly be possible. t what can be done in this matter has again been wn at Brisbane General Hospital where, in 99 of a group of 119 cases of serious cancer treated, tions for pathological examination were prepared l reported upon.

The question of the follow-up of cases after treat-nt is giving some little difficulty in certain quarters, the number of cases so far that have been missing omparatively small. Again in this respect Brisbane s an example, as in the case records for that centre ainst the names of only two patients was it found essary to insert the statement "no information ained."

THE FUTURE.

So far it can certainly be said that the Australian periment in cancer treatment and organisation s been fully justified, and a very large number of ple who would not otherwise have obtained it e been completely or partially relieved of the nptoms or signs of cancer, and it is generally felt t this work has been all to the good with a definite mise of steady progress in the future. In all tres the predominant feeling is one of hopefulness l confidence. There now remains the necessity for intaining and improving the standard of cancer atment throughout Australia by the control and provement of old techniques together with the roduction of new ones. It is also necessary that this at national experiment should be maintained as a ty and that the whole organisation should be t on its present basis, by which means uniformity methods of treatment, of recording cases, and of owing-up results will be maintained and any new hods, both from home and abroad, brought rapidly he notice of the various centres.

The organisation that has been laid down is the leus of a great scheme and represents an attempt deal with the cancer problem on modern lines by hods which bring to bear on the question both ional and local powers of organisation and iative.

XTENSIONS AT PAPWORTH SETTLEMENT.—ce George has opened the large new cabinet-making , the foundation-stone of which was laid a year ago the Duke of York, at Papworth Village Colony. His al Highness commented upon what he described as the traordinary fact" that not a single child of the married rculous members of the colony has suffered from rculosis.

THE NATURE OF MILTON'S BLINDNESS.

THE conjectural diagnosis of the cause of Milton's blindness is an interesting exercise to which an article is devoted by Mr. Arnold Sorsby in the July number of the *British Journal of Ophthalmology*. The known facts are briefly as follows. In the first place we know that the blindness was not due to any externally visible affection. In the sonnet addressed to his friend Cyriak Skinner, Milton says:

> "Cyriak, this three years' day these eyes though clear
> To outward view, of blemish or of spot,
> Bereft of light, their seeing have forgot."

As a boy Milton was so studious that from the age of 12 he scarcely ever went from his lessons to bed before midnight "which indeed was the first cause of injury to my eyes, to whose natural weakness their were also added frequent headaches." Nevertheless in his early years he was skilled in using the sword, so that the defect of sight at that time could not have been very great. It was not until about the age of 35 that the trouble with his eyes became very serious, but even then he would not spare himself. He says:

> "When I was publicly solicited to write a reply to the defence of the royal cause; when I had to contend with the pressure of sickness and with the apprehension of soon losing the sight of my remaining eye; and when my medical attendants clearly announced that if I did engage in the work, it would be irreparably lost—their premonition caused no hesitation and inspired no dismay."

In describing the onset of his blindness in a letter intended to be shown to Dr. Thevenot, a Parisian oculist of great repute, he says, writing in 1654, when he had been blind for about three years:

> "It is ten years, I think, more or less since I felt my sight getting weak and dull, and at the same time my viscera generally out of sorts. In the morning if I began as usual to read anything, I felt my eyes at once thoroughly pained, and shrinking from the act of reading, but refreshed after moderate bodily exercise. If I looked at a lit candle a kind of iris seemed to snatch it from me. Not very long after a darkness coming over the left part of my left eye (for that eye became clouded some years before the other), removed from my vision all objects situated on that side. Objects in front also, if I chanced to close the right eye, seemed smaller. The other eye also failing perceptibly and gradually through a period of three years, I observed some months before my sight was wholly gone, that objects I looked at without myself moving, seemed all to swim, now to the right, now to the left."

From this passage, and especially from the mention of a "kind of iris" when he looked at a candle, some writers have argued that Milton's disease was chronic glaucoma. As Mr. Sorsby points out, however, it is a large assumption that the expression "kind of iris" alludes to the rainbow colours round lights which are sometimes seen in glaucoma, and the age of onset—the early thirties—as well as the nature of the field defect, occurring suddenly, and temporal, not nasal, in position—are distinctly against that diagnosis.

On the other hand, there is good reason to believe that Milton suffered from progressive myopia. The early trouble with his eyes brought on by excessive study points to this. Later, the sudden loss of the temporal field in his left eye suggests very strongly a detachment of the retina in that eye. It was three years after the loss of sight in the left eye that the right one appears to have followed suit. Its gradual failure and Milton's own description of the swimming about of objects, culminating in complete blindness save for perception of light, suggests a progressive myopia leading to a retinal detachment. This presumption is strengthened by the knowledge that Milton in his youth had trouble with his eyes connected with overwork. We may presume that he was born with an hereditary tendency to myopia (his father, we are told, read without spectacles at the age of 84); that his studious life favoured the development of the myopia and of the choroido-retinal degeneration that so often attends it; that the sudden failure of vision in the left eye was due to retinal detachment; and that the gradual failure of the right, though it

may have been due solely to retinal degeneration, was very probably completed by a second detachment. The theory of detachment was first mooted by Dr. Dufour, of Lausanne, in 1909. Mr. Sorsby discusses other theories, but we agree with him that this one is by far the most probable.

A MEMORIAL TO MARGARET MACDOWALL.

To the Editor of THE LANCET.

SIR,—It has been suggested by some of those who knew and admired Margaret Macdowall and her work for children of limited intelligence, that many might care to subscribe to a memorial. It is thought that such a memorial might take the form of a new edition of her book, "Simple Beginnings in the Training of Mentally Deficient Children." This book, which was first published in 1919, and is still in constant demand, has now been out of print for some time, and it is estimated that a new edition, with some biographical notes added, would cost approximately £100. If, as is hoped, the response to this appeal brings in a substantial sum, it is proposed to use the balance, and any proceeds from the sale of the book, to create a fund from which grants or loans could be made to help educated girls to train for work among mentally deficient children. Mr. Harold Moreland has kindly consented to act as treasurer of the fund, and will acknowledge any donations, large or small, sent to him at Cherrycroft, Gerrards Cross, Bucks. The fund will close on Oct. 31st.

We are, Sir, yours faithfully,

R. COCKBURN.	BERTHA JAMES.
MAURICE CRAIG.	E. F. PINSENT.
EVELYN FOX.	A. F. TREDGOLD.

August 12th, 1930.

ULCERS OF THE SKIN.

THE first two papers in the July number of the *Archiv für Schiffs- und Tropen-Hygiene* describe unusual cases of ulcer of the skin. On p. 345 Dr. H. Ziemann and Dr. A. Waegener tell of a German planter in Portuguese East Africa, aged 28, who in April, 1927, fell into a ditch and grazed his right knee externally. In a fortnight the wound began to inflame. The local doctor treated him with two intravenous injections of neosalvarsan, and with caustic and permanganate, but ultimately he had to come home, and in June, 1928, came under care in hospital in Berlin. There were several ulcers on the outside of the knee, extending along the lower third of the thigh and the upper end of the leg, the edges of the ulcers were pigmented and rolled, many suppurating pockets were found, and the knee was flexed to an angle of 130°. Serial photographs reproduce the appearances (at first very discouraging) from time to time. All kinds of treatment were used, drugs, X rays, sunlight, autovaccines, antiserum, skin grafting, without avail, until on Sept. 26th, Dr. Ziemann found in scrapings, not from the floor but from the edge where there was no suppuration, leishmania parasites, when he ordered an intravenous injection of stibenyl 0·1 g. to be given. This very small dose caused a severe reaction—collapse and later albuminuria with casts. Four days later 0·01 g. stibenyl was given intramuscularly, and as tolerance increased the dose was raised to 0·3 g. The ulcers were dressed with philonin ointment (copper iod-ortho-oxychinolin-sulphate and silver sulphate, āā 0·1 g., boric acid and acridin, āā 1 g., balsam of peru, 10 g., irradiated cholesterol, 0·25 g., zinc ointment to 100 g.) an ointment said to be very useful for wounds that do not heal. The patient still had reaction from the stibenyl treatment, but his ulcers began to heal rapidly, and he was discharged from hospital on Nov. 2nd, and was later reported completely cured. The authors note that this is the first report of leishmania of the skin from East Africa. They suggest that the original wound was probably infected by a phlebotomus carrying the parasite. The monocytosis in the blood was never higher than 4 per cent. The history of this case shows the importance of seeking leishmania parasites at spots where there is no suppuration.

The other communication (p. 351) is by Dr. Garry, surgeon to a Jerusalem hospital, reporting an epidemic of ulcers on and about the ankle, which occurred in Palestine in 1920. About 10 patients were seen by Dr. Garry, mostly poor people, who came from the coast and walked barefoot. Fusiform bacilli were often present, but could never be cultivated. The ulcer first appeared as a papule the size of a pea, red and tender. Next day there was effusion, occasionally pus, drying to a scab, under which an ulcer formed in two or three days, covered with what sometimes looked like a diphtheric membrane. The ulcers were very painful at night. No lymphangitis was noticeable. They healed spontaneously in about two months. Dr. Garry tried many remedies, the most successful being lactic acid dusted into the lesion under a wet saline dressing. A single application only was needed in some cases. All the ulcers so treated healed within three weeks.

TONSILLECTOMY IN RHEUMATIC FEVER

IN what they describe as a preliminary report[1] William Robey and Dr. Maxwell Finland, of Boston, "unhesitatingly offer tonsillectomy as a safe therapeutic measure" during the acute attack of rheumatic fever, and claim that in several cases "the results have been brilliant." Referring to the figures upon which this double claim is based, one finds that out of 50 cases operated upon during the acute attack no less than 13 (that is, over 25 per cent.) are admitted to have had a definite exacerbation of symptoms. The criteria selected for comparing with the results of ordinary medical treatment are the number of days of elevated temperature, the number of days of joint symptoms, and the duration of the patient's stay in hospital. From the tables presented few conclusions can be drawn; the average duration of joint symptoms is recorded as 40 days in operated and 36 in unoperated cases (which seems very high), while the temperature remained raised in the operated cases for an average of ten and in the unoperated cases of eight days. Thus even if these criteria are regarded as sufficient, they do not provide any basis for the main claims of the paper.

No attempt was made to follow up the cases after discharge from hospital, and apparently the view was taken that the operation may, at least in certain successful cases, be taken as a cure. But the chief characteristic of rheumatic fever is a sudden or, more often, insidious invasion of the heart and nervous system by the causative virus, so that a follow-up of cases over a long period can be the only means of estimating the results of any specific course of treatment. Robey and Finland recognize, indeed, that "an initial attack or a recurrence may take place after tonsillectomy," but even this does not give them pause in "unhesitatingly offering tonsillectomy."

ROASTING AN OX.—In aid of Loughborough Hospital, an ox has been roasted whole at Kegworth. It weighed 40 st., cost £20, and was roasted and eaten in the field in which it had grazed during its two years of life. The first slice, which was declared to be "well and truly cut," was sold for £4 10s.

LEEDS PUBLIC ASSISTANCE HOSPITALS.—The Leeds public assistance committee has given approval to a scheme for the appropriation of St. Mary's Infirmary, St. James's Hospital, and Rothwell Infirmary for the use of the sick of the city, whether poor or not. St. James's Hospital, which of late years has been used by the guardians as a general hospital, is to be adapted for the treatment of the acutely sick.

ADDRESSES AND ORIGINAL ARTICLES

DIABETES AS A PHYSIOLOGICAL PROBLEM.*

By J. J. R. Macleod, M.B., LL.D. Aberd., F.R.C.P. Lond., D.Sc. (Hon.) Toronto, F.R.S.,
REGIUS PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF ABERDEEN.

LECTURE I.

These lectures give me the opportunity to present a review of certain investigations in experimental diabetes, which have been carried out during the past few years under my direction in the Physiological Laboratory of the University of Toronto. Most of these researches will be dealt with in the first lecture and, in the second one, I shall consider a problem in metabolism which is now coming to the forefront in both laboratory and clinic—namely, the control of the secretion of insulin.

History of Two Depancreatised Dogs.

I shall begin by giving a short account of the clinical history of two dogs which were kept alive by treatment with insulin for about four years after complete removal of the pancreas. The animals remained throughout this time in excellent condition, and death occurred in one of them on the fifth, and in the other on the sixth day after discontinuing insulin. There cannot be the slightest doubt that both dogs would have survived to the full span of their normal lives had the treatment been continued.

I regret now that this plan was not followed. The reason for removing insulin was to determine the intensity of the resulting diabetes by observing, among other things, the behaviour of the respiratory quotient, and it was intended that this should be done on the third and fourth days. Unfortunately, a serious fire broke out in the laboratory on the morning of the third day, and it took all this day to repair damage to the respiratory apparatus. The dogs being as yet apparently unaffected, it was decided to continue with the programme as originally planned, except that the respiratory observations were postponed to the fourth and fifth days. Although we knew from our experience with other similarly treated dogs that we were incurring grave risks of losing the animals from coma, on account of their fattened condition, we expected to be able to guard against this by treatment with insulin immediately any definite symptoms, such as vomiting and drowsiness, showed themselves. But unfortunately, these symptoms only developed after it was too late to save the animals.

During their sojourn in the laboratory, both dogs were under constant observation and each was occasionally used in the first year for experiments relating to diabetes. Several of the results have been published from time to time, and in the clinical histories which I now offer I will indicate where these may be found. It will be convenient if I first of all give an account of each animal during the course of the insulin treatment, and then describe that of the diabetes which supervened when it was discontinued.

1. Dog 23, a female mongrel, weighing about 8 kg., was completely depancreatised on Sept. 17th, 1923, by Dr. F. N. Allan. It was kept on a diet of meat and cane sugar with insulin injections twice daily, on which it maintained its weight fairly well. On March 5th, 1924, it was used by Drs. Allan and Sokhey in their investigations of the effect of diabetes and of insulin on the excretion of phosphorus.[1] On March 8th this observation had to be terminated by giving food and insulin, because of unfavourable symptoms. At this time the dog weighed 7 kg. It was placed on the retired list and raw pancreas was added to its food, in view of the observations of Allan, Bowie, Macleod, and Robinson[2] that this addition prevents the occurrence of serious and often fatal hepatic changes in insulin-treated, depancreatised animals. An amount of sugar considerably exceeding the assimilation limit was also given daily, so that marked glycosuria was always present. This was done in order to avoid risk of the development of hypoglycæmic symptoms in the night, from which other animals had been lost. On Oct. 12th, 1926, the weight had increased to 10·8 kg., and the only fact worth recording during the interval is that the dog on several occasions was mated while in heat, but did not become pregnant. It was now being fed twice daily with 200 g. raw lean meat, 50 g. raw pancreas, and 50 g. cane sugar, and 16 units of insulin were injected before each feeding. A conditioned salivary reflex had become established, so that whenever the attendant approached the cage with the hypodermic syringe in his hands the animal pressed its body against the bars and salivated profusely in anticipation of the feeding which was to follow. From Oct. 12th to 15th, the 24 hours' urine was collected and respiratory observations were made on the 12th and 14th. The average daily excretion of nitrogen was 13·9 g., and of glucose 82·3 g. Assuming that a D : N ratio of 3·65 would have obtained if protein alone had been metabolised, the total glucose intake works out at 156 g. (51 g. from protein and 105 g. from cane sugar), so that 74 g. of glucose was used, and the glucose equivalent † of one unit of insulin was 2·3. On Oct. 6th and 14th the respiratory quotient was 0·86 and the energy expenditure 69 calories per kg. and day; on the 15th these values were 0·83 and 74·5 respectively. There were no ketone bodies in the urine.

About a year later, on Sept. 27th, 1927, another similar metabolic study was conducted by J. J. Weber, the animal during the interval being on the above diet and always in apparently normal condition, very lively and vociferous. At this time it weighed 11·2 kg. Urine was collected daily until Oct. 6th, the average daily excretion of nitrogen being 11·2 g. and the carbohydrate utilisation 136 g., giving a glucose equivalent of 4·25. On Sept. 29th the respiratory quotient was 0·922 and the energy expenditure 78·5 calories per kg. and day; on Oct. 27th these values were 0·904 and 72·3 calories respectively. As judged from the behaviour of both the glucose equivalents and the quotient, the animal was utilising more carbohydrate than it had done a year previously. Similar metabolic studies were again undertaken by Mr. Weber from Oct. 31st to Nov. 4th, and from Nov. 29th and Dec. 6th, with the results given in Table I.

Table I.

1927.	Weight.	Average daily nitrogen excretion.	Average daily glucose utilised.	Glucose equivalents.
	kg.	g.	g.	
Oct. 31st to Nov. 4th.	13·5 to 12·5	13·54	143·4	4·3
Nov. 29th to Dec. 6th.	14·1 to 11·3	13·6	117	3·65

Respiratory analyses were made on two of the days of each period, the average quotient for the first one being 0·906 and the energy expenditure 71·7 calories per kg. and day; for the second period these values were 0·917 and 69·4 calories respectively. No traces, either of ketone bodies or of albumin were found in the urine, which was tested for their presence daily.

2. Dog 32, a female Irish setter, weighing 7·27 kg., was depancreatised by Dr. Allan on Feb. 14th, 1924. The subsequent history of this animal up to March 24th, 1925, has already been published by Markowitz and Simpson.[3 4] The most noteworthy incident during this period was that the dog became pregnant and gave birth on Jan. 1st, 1925, to six pups, three being born dead. The milk flow was good, and the mother suckled the three pups. On Jan. 2nd she developed marked symptoms of hypoglycæmia, and the blood-sugar was found to be 0·067 per cent. Prompt recovery was effected by injection of glucose. Since the dose of insulin and the food intake had not been changed, it was concluded that loss of sugar in the milk, which was

*The Oliver-Sharpey Lectures delivered before the Royal College of Physicians of London on April 29th and May 1st.

† This equivalent is obtained by dividing the grammes of glucose utilised by the number of units of insulin injected.

being secreted plentifully, was responsible for the hypoglycæmia. From now on the blood-sugar concentration was measured daily, and since it did not again reach a dangerously low level, no change was made in the standard diet or the dosage of insulin. On Feb. 1st, 1925, the pups were weaned, and during March the carbohydrate balance of the mother was determined for a period of a week. It is interesting to compare the results at this time with those obtained between Oct. 25th and Dec. 25th, 1924. This is done in Table II.

March 3–7 ..	10·0 After	12·2	133·5	4·17
„ 22–24 ..	10·0 weaning.	12·4	121·7	3·8

As pregnancy advanced the excretion of nitrogen declined, due to retention of nitrogen by the fœtuses. At the same time there was a slight falling-off in the utilisation of glucose, which indicates that no significant amount of insulin could have been added to the maternal organism from the fœtal pancreas. After weaning, the carbohydrate balance was practically the same as it had been six months previously.

During the next 18 months the dog was maintained in a perfectly healthy state on the standard diet and the usual insulin dosage. She did not again become pregnant, although frequently mated while in heat. The urine always contained sugar. The next metabolic observation was undertaken by Dr. Chaikoff between Oct. 7th and 13th, 1926, when the dog weighed 12 kg. The average daily excretion of nitrogen was 14·6 g. and the glucose utilised was 126 g., giving a glucose equivalent of 3·9. The average respiratory quotient of two of the days was 0·885, and the energy expenditure 63·9 calories per kg. and day.

Between September and December, 1927, metabolic observations were undertaken by J. J. Weber on three occasions of one week each. The average results for each period were as shown in Table III.

TABLE III.

1927.	Weight.	Average daily nitrogen excretion.	Average daily glucose utilised.	Glucose equivalents.	R.Q.	Calories.
	kg.	g.	g.			per kg.
Sept. 30th–Oct. 6th.	13·0	13·5	134	4·2	0·876	64·5
Oct. 31st.–Nov. 9th.	13·4	15·0	143	4·4	0·903	60·3
Nov. 29th.–Dec. 6th.	13·8	14·45	119	3·7	0·909	60·1

The urine was always found to be free of ketones and protein. The morning blood-sugars on Dec. 9th and 10th were 0·440 and 0·440 per cent. respectively. It is clearly shown that no change had occurred in the assimilative power for carbohydrate, although a large proportion of the available sugar was metabolised.

The remarkable constancy in the metabolic balances over a period of several years in both these animals shows conclusively that no agency could have become developed in the body to alter the assimilative powers for carbohydrate.

The choice of diet was made in the light of various trials on other depancreatised animals. In the first attempts meat alone was fed, but although it was greedily consumed there was a steady fall in body-weight and symptoms of poor nutrition usually supervened. On this diet, however, Banting and Best [5] succeeded in keeping a dog in good condition for over two months, when it was killed. To prevent the emaciation, cane sugar was added to the diet (with corresponding increase in insulin dosage), but although this had the desired effect and anima could now be kept alive for periods up to eight month they ultimately succumbed to a condition in whic symptoms of acute jaundice were prominent; th was found on post-mortem examination to b associated with extreme fatty changes in the live There was also during life evidence of very imperfec digestion of the food, the fæces containing muc undigested muscle-fibre besides large quantities fat. Believing that the absence of pancreat ferments, upon which this inadequate digestio obviously depended, might be related to the hepat changes, it was decided to add raw pancreas (50 g.) the daily diet. The resulting improvement, both the condition of the fæces and the general well-bein of the animals, was very striking. The experien of M. E. Hédon [6] corroborates ours, but that Penau and Simonnet [7] does not. These worke succeeded in keeping a depancreatised dog for 74 days on insulin and a diet composed of meat, milk, an bread, with powdered lime. Hershey, in the Toron laboratory, has been investigating this problem, an by feeding easily digestible fats, particularly lecithi has succeeded in keeping several depancreatised do alive for considerably over eight months, but w must await his report before we can say wheth healthy survival is possible without administratio of pancreas. My impression is that dogs may va and that their ability to survive is related to th presence or absence of nodules of pancreatic tissue the submucous layers of the duodenum. Bowie has found that, in about 50 per cent. of both norm and depancreatised dogs, pancreatic nodules can detected in the duodenal wall, closely associated wi the pancreatic ducts. These nodules do not conta islet tissue, but they may secrete into the intesti just sufficient pancreatic juice to have a favourab effect on digestion.

The fattening effect of insulin and sugar is usual very marked in depancreatised animals, and w early noted in rabbits that were repeatedly used f the assay of insulin, especially when sugar had al to be given because of convulsions. In norm animals, however, the fattening does not contin for long, even although the insulin and sugar a continued, as we have shown by carefully controll observations on pigs at the Rowett Institute (Mage Macleod, and Middleton [11a]). In animals of su normal weight, on the other hand, the treatment m be of value.

PREGNANCY DURING DIABETES.

Our failure to detect any influence of pregnan on the diabetic symptoms of dog 32 prompt Markowitz and Soskin [8] to repeat the observatio on other animals with equally negative results. two dogs that were depancreatised during the lat stages of pregnancy, and thereafter given small dos of insulin, the partial diabetes which supervened w as severe as after pancreatectomy in non-pregna animals. These results are apparently at varian with those obtained by Lawrence [9] in the case of diabetic woman. During the first 27 weeks of t pregnancy the diabetes was severe, and the patie required 44 units of insulin a day, but it improv greatly during the following 10 weeks, at the end which Cæsarean section had to be performed account of nephritis. Just before the delivery (twins) the carbohydrate tolerance had increased far as to make it unnecessary to give insulin, a Lawrence computed that 100 g. more of carbohydra could be tolerated than before the pregnancy. Aft delivery the diabetic condition became worse agai The record certainly sustains the view that th

etuses from the twenty-eighth week on were contributing sufficient insulin to combat the diabetic ymptoms in the mother, and it also gives evidence o show that their secretory powers became stimulated hen the percentage of sugar in the mother's blood as raised by the administration of sugar.

It is difficult to reconcile these conflicting results. here are, however, at least two points of difference etween our experiments and the observations of awrence. These are: (1) the dogs were completely epancreatised, whereas the patient was still in ossession of some islet tissue; and (2) the dogs were eceiving relatively much more insulin *plus* carbohydrate than the patient. In the light of what we now now regarding the variations which may occur in the ontrol of the internal secretion of insulin, it is quite ossible that the remaining healthy islets of the nother's pancreas were stimulated to secrete more much heavier than when she first came under observation. Both animals were decidedly fatter than the average. As has already been remarked, neither showed symptoms of any kind until within a short period of death. The results of the metabolic studies were exactly what was expected in the light of those obtained from the numerous other fattened diabetic animals which have been observed in the Toronto laboratories, and they stand out in sharp contrast with those obtained on lean animals which will be dealt with later.

The D : N ratio of dog 23 on the second day after removal of insulin stood at 6·01, and that of dog 32, on the third day, was 4·12. On the following days, in the case of both animals, respiratory observations were made during the forenoon; sugar was then given and the respiratory measurements continued during the afternoon. A small but decided rise occurred in the respiratory quotient, and a small but variable proportion of the sugar reappeared in the urine. The total ketone excretion in dog 32 was of about the same magnitude

insulin, and that regeneration of new islets occurred s the pregnancy advanced. That this may have ccurred is at least suggested by the fact that for me time after delivery the diabetic symptoms of e mother were less severe than they had been uring the earlier weeks of the pregnancy. But they timately returned, which would seem to indicate at a temporary improvement in the secretory nction of the maternal pancreas was responsible r the amelioration. On the other hand, evidence pporting the view that the fœtal insulin had nefited the mother in Lawrence's case is found the fact that the blood-sugar at the time of delivery as much lower in the fœtal than in the maternal ood. The second difference may explain why we ere unable to demonstrate any fœtal contribution insulin, for it is well known that when insulin is latively in excess of the carbohydrate turnover the ldition of each extra unit has a much lesser effect an otherwise.

OURSE OF DIABETES ON WITHDRAWING INSULIN FROM TREATED ANIMALS.

The observations were undertaken by Dr. Soskin, nd the results of the urinary and respiratory analyses e given in Table IV.

It will be observed that dog 23 was somewhat ghter than she had been a few months earlier—1·4 kg. as compared with 14·1 kg.—but that dog 32 ad practically maintained her weight and was per kilogramme body-weight as the largest reported in man (0·45 g. per kg. for man), and it was not demonstrably affected by the ingestion of sugar, although this probably was responsible for the ketone excretion not rising to higher levels than it did. Unfortunately, the blood was not examined.

At post-mortem examination it was found that pancreatectomy had been complete in both animals. The duodenal wall adjacent to the bile and pancreatic ducts was examined microscopically by Drs. D. J. Bowie and W. L. Robinson. No pancreatic tissue could be detected in the case of No. 23, but a small piece embedded in the submucosa was found near the stub of the chief pancreatic duct in No. 32. This measured 2 mm. by 3 mm., and

TABLE V.

	Sample.	Dog 23. Per cent.	Dog 32. Per cent.
Muscle glycogen .	1.	0·111	0·16
	2.	0·173	0·15

	2.	0·049	0·061
Liver fat ..	1.	44·31	41·9
	2.	44·24	41·9

apparently had no duct connexion with the intestine. Only a few of the cells composing it contained violet-staining granules, probably zymogen. A most careful search, in which the special staining methods previously described by Bowie were used,[10] failed to reveal any islets. It may be remarked that this was to be expected, in view of our experience with numerous similar pancreatic nodules in other animals (cf. Bowie [11]). There was much subcutaneous and mesenteric fat, especially in No. 32. All the organs appeared to be healthy on naked-eye examination, but the liver was large and pale. Microscopic examination did not reveal anything of note, except that the liver cells were very large and vacuolated, and the circular muscle-fibres of

the aorta were swollen and shreddy in appearance. In the latter also, areas were noted in which gelatinous changes, leaving open spaces, had occurred. There was no hardening of the arteries. Chemical analysis was made of the muscles for glycogen and of the liver for glycogen and fat.

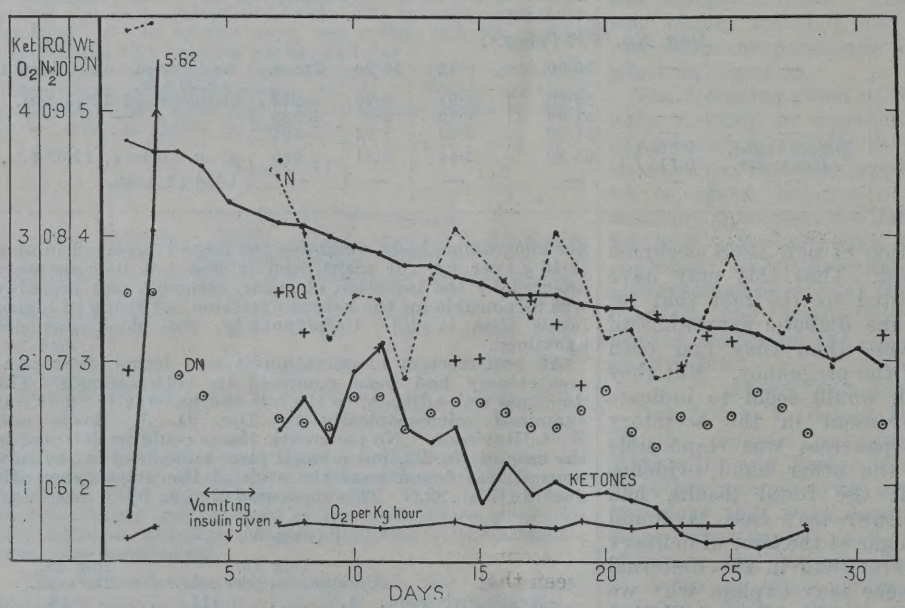
The results were as given in Table V. The very low glycogen and the high fat content of the liver are noteworthy.

When we bear in mind that the normal span of life of a dog is 12–15 years and that of a man 60–70, we may assume that the four years during which both these completely depancreatised animals lived would correspond to 20 years in the case of man, and undoubtedly, had the insulin treatment not been discontinued, the dogs would have survived much longer. None of the symptoms of cataract, of gangrene, of arterio-sclerosis or of nephritis, which some have supposed may supervene after the blood-sugar has been supernormal for some time, was manifested by either animal.

The Course of Pancreatic Diabetes when Food but No Insulin is Given.

In view of the great accession to our knowledge of diabetes which resulted from von Mehring's and Minkowski's discovery that this disease follows experimental removal of the pancreas, it is surprising that the number of complete records of the condition is not large. The literature is surfeited with accounts of the symptoms and the clinical history of diabetes mellitus in man, but, although these accounts have given useful guidance in its diagnosis and dietetic treatment, they have not taught us as much as have

FIG. 1.



Curves showing the behaviour of body-weight, excretion of nitrogen and ketone bodies, respiratory quotient, D:N ratio, and the oxygen consumption in a depancreatised animal during a period of a month after removal of insulin. The values for the various curves are indicated in the columns along the ordinates. Time in days is given on the abscissa. + = R.Q. ⊙ = D:N ratio.

the experimental investigations concerning either the fundamental cause of the disease or its rational treatment. The reason for this is probably because the most severe cases in man are never completely diabetic (cf. Joslin,[12]) there being always some more or less undamaged islet tissue left in the pancreas. Not only will the insulin which this secretes prevent diabetes from developing to its full intensity but—and this is more serious from the scientific point of view—the secretion will not be constant from day to day. These variations in the internal secretion of insulin have been responsible for many errors of judgment regarding the efficacy of this or that therapeutic measure in treating the disease. From time to time, for example, various substances have been advocated as antidiabetic remedies because they brought about some diminution in the glycosuria or seemed to effect a temporary improvement in the clinical condition. In some countries local plants have for long had a reputation as remedies, more especially those of the myrtle family. But so long as some islet cells remain functional it is most likely that any beneficial action which such substances may temporarily display is due to their stimulating influence on the secretion of insulin, and it is evident if this be the case, that their prolonged administration must be detrimental, since over-stimulation of the already weakened islets will lead to exhaustion and further decay. On several occasions I have had sent to me various of these reputed remedies with such assurances of their efficacy from the clinical standpoint that I have investigated their action on depancreatised dogs, the invariable result being that they had no effect on the diabetic symptoms. They did not alter the symptoms in complete diabetes although they may have temporarily alleviated them in the incomplete form of the disease as met in man.

In view of these facts it is clear, I think, that experimental pancreatic diabetes must be regarded as the final court of appeal in giving a decision as to whether any drug or other remedial measure should be used in the treatment of diabetes in man. As I would further insist that the reputed remedy must be capable not only of removing the symptoms of the disease but also, by its repeated administration, of maintaining the animal in normal condition, as we have seen insulin can do. Since, therefore, the depancreatised animal is indispensable in the investigation of the problems of diabetes, it is important that we know precisely for how long it may live and the behaviour of the symptoms when no remedial measures are taken. Dr. Soskin[13] has just completed an investigation along these lines in Toronto, and, with his permission, I will refer to some of the most important facts which he has brought to light.

After depancreatisation, the animals were treated with insulin for some weeks before the observations were started. They were all apparently in good condition when the insulin was withdrawn, and none of them was excessively fat. As we have seen, fatter animals never survive for more than five or six days after removal of insulin, so that they would have been unsuitable for one of Dr. Soskin's main purposes, which was to see for how long a depancreatised animal can remain alive without insulin, but with every other care. In all cases food (meat, gelat-

and casein) and water were allowed throughout the observation, although several of the animals refused to take the former. The urine was collected daily and the amounts of glucose, nitrogen and ketone bodies in it were determined. On certain days also the animals were placed, usually for periods of two or three hours each, in a respiratory apparatus of the Benedict type. I have described this apparatus elsewhere,[13a] and need only remark here that its accuracy was proved periodically by burning measured amounts of alcohol in it.

The observation, of which the results are shown in the curves of Fig. 1, is the most complete we have on record. The animal took food (300 g. lean meat, containing therefore 60 g. protein and 30 g. fat) throughout, and excreted several grammes of nitrogen less than was contained in the food, owing, no doubt, to imperfect digestion and absorption in the absence of a secretion of pancreatic juice. The very considerable variability in the nitrogen excretion is probably also to be related to the faulty digestion. The D : N ratios after the first week averaged about 2·6, but varied somewhat from day to day, and it is interesting to note that they ran more or less parallel with the nitrogen excretion, a relationship which was also noted in other animals of the series. This would seem to indicate that increased protein metabolism was accompanied by the excretion of a greater proportion of the sugar derived from this source. The ketonuria started on the first day of the diabetes and became very high on the third and fourth when, indeed, vomiting, which in dogs is the first general symptom of coma, became so acute that insulin had to be administered in order to save the animal. After this the ketonuria gradually declined and although, no doubt, the administration of insulin was responsible for the inception of the recovery, it is significant that in other depancreatised animals not so treated the ketonuria usually attained a maximum about the fifth day, and then gradually declined without insulin. This stands out in sharp contrast with the course of the ketosis in fattened animals, which do not survive the coma unless treated immediately upon the appearance of its first symptoms. In only one case in the series, the results of which are given in the curves of Fig. 2, did severe ketonuria develop at a later stage. The respiratory quotient in the animal of Fig. 1 varied between 0·680 and 0·727, the higher quotients being caused by an increase in carbon dioxide expired rather than by a decrease in oxygen retained in the body. No relationship can be traced between variations in the quotient and the glycosuria or ketonuria.

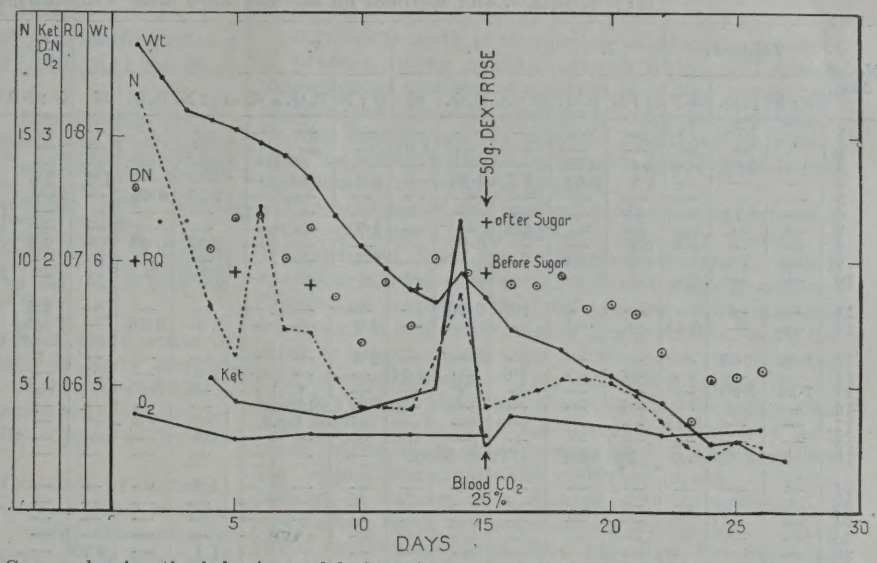
The second of the charts (Fig. 2) shows the course of the diabetic symptoms in an animal which did not regularly take its food. Towards the end of the second week of the observation, the ketonuria, which had previously been moderate, became very marked, and was accompanied by a great increase in the excretion of nitrogen and a fall in the percentage of carbon dioxide in the blood. Curiously enough, also, the body-weight at this stage increased for a day or so, but the notes do not indicate to what this was due. After the fifteenth day, on which sugar was given, the body-weight, the nitrogen excretion, and the D : N ratios all fell steadily until the twenty-sixth day, when the ratio was 1·14. The ketonuria and the carbon dioxide content of the blood remained steady.

The Significance of the D : N Ratio and the Respiratory Quotient in Diabetes.

Tables VI. and VII. are compiled from Dr. Soskin's protocols, and they show the most significant results obtained with regard to the D : N ratio, the respiratory quotient, the ketone body excretion, and the proportion of sugar recovered in the urine after sugar ingestion.

It is seen that after the third day of the diabetes the D : N ratios were usually at or slightly above

FIG. 2.



Curves showing the behaviour of body-weight, excretion of nitrogen and ketone bodies, respiratory quotient, D : N ratio and the oxygen consumption in a depancreatised animal during the period of a month after the removal of insulin. The values for the various curves are indicated in the columns along the ordinates. Time in days is given on the abscissa. + = R.Q. ⊙ = D : N ratio.

2·5 in four of the animals, including those of which the results are shown in the curves. In the remaining six animals the ratio was never over 2, and it varied considerably. Since there can be no doubt that extirpation of the pancreas was complete in every case, these results show the fallacy of taking the D : N ratio as a criterion of the intensity of the diabetes, as Markowitz and I pointed out several years ago.[14]

The behaviour of the respiratory quotient was also contrary to common belief. In phlorhidzin poisoning, as also in human diabetes, the quotient is between 0·660 and 0·707 when allowance is made for the protein metabolised. During the past few years it has been frequently measured in depancreatised dogs in the laboratory at Toronto, and has also been found at correspondingly low levels, at least during the week or so after removal of insulin, and we were greatly surprised when L. Hédon published results showing that much higher quotients may occur at later stages of the diabetes.[15] It was, indeed, partly to satisfy ourselves that this is really the case that the present observations were undertaken, and it can be seen that high quotients were observed in three of the nine animals in which respiratory observations were made. Confirming Hédon, it was found that the high quotients occurred at a late stage of the diabetes, and since an increase in carbon dioxide excretion rather than a decrease in oxygen-uptake was responsible for them, the question arose whether they might depend on a state of acidosis. Dr. Soskin therefore determined the alkali reserve of the blood (Van Slyke method) in many of the animals, but without finding that this bore any relationship to the high quotients. It is true that he sometimes found very low values for carbon dioxide—25·5 volumes per cent. in one case—but there was no apparent parallelism between this and the respiratory quotient. Hédon

suggests that, since the high quotients are most usually seen after the diabetes has existed for some time, they may be due to a loss of power by the liver to convert protein and fat into carbohydrate, a process which, by absorbing oxygen, would keep the quotient at a low level. He believes that combustion of what carbohydrate remains in the body is responsible for the higher quotient, but it is difficult to see how the energy thus derived could maintain the animal in life for more than a few hours.

RECOVERY OF INGESTED SUGAR.

Perhaps the most interesting of the results were those relating to the extent to which administered glucose reappeared in the urine, and its effect on the respiratory quotient and the excretion of nitrogen. In every instance the ingestion of glucose caused an increase in respiratory quotient, and a decrease in the excretion of nitrogen (Table VII). The results confirm those of Wierzuckowski [16] (see also Deuel, Wilson, and Milhorat [17]), who also observed in phlorhidzin-poisoned dogs that the rise in respiratory quotient was particularly well marked when the glucose was given in two portions, one an hour o so after the other, a procedure which was followe in many of the present experiments.

* Calculated by usual method allowing for fall in nitrogen.
† Taken several days previously. ‡ Died on 13th day. § Died on 38th day.

Much of the ingested sugar reappeared in the urine and a rough general parallelism can be seen betwee the proportion which reappeared and the extent o the rise in respiratory quotient. Although calculation in metabolism are treacherous unless all the data hav been observed over long periods of time, it is never theless often useful to attempt them with the shorte period data, on the assumption that the latte correspond to what the former would have been On this basis we may calculate from the amoun of sugar utilised the extent to which the quotien would be expected to rise.

Thus on the twenty-third day of Experiment IX., whe the most marked rise in respiratory quotient occurred, th oxygen consumption per kg. body-weight and per hou before sugar was 723 c.cm., or 128·4 litres in 24 hours, an the quotient, 0·714 (cf. Soskin's tables [13]). According t the Zunz-Lusk tables, this means that the total hea production was 603·5 calories, and that 3 per cent. of carbo hydrate was used to produce it, equalling 18 calories, o 4·3 g., of carbohydrate. After sugar the quotient rose t 0·813, which means that 36 per cent. of the energy came fro carbohydrate and, assuming that this level was maintained then, during a period of eight hours, 43·2 litres of oxyge were used, or $43·2 \times 4·82 = 208$ calories, or 50·8 o carbohydrate. The excess consumed, according to th respiratory analysis, was, therefore, somewhere about 47 g. whereas actually 63·6 g. of glucose disappeared.

The most important result of the research is tha both the respiratory quotient and the sugar balanc show definitely that the completely diabetic anima is capable of oxidising large amounts of carbo hydrate and, this being so, it is not surprising that th excretion of nitrogen should fall decidedly. Thu one more nail is put in the coffin of the long moribun

d now quite dead theory that diabetes is due to a
s of power by the tissues to oxidise carbohydrate.
is power may be depressed, as I have elsewhere
inted out,[21] but this depression is probably
ondary to other disturbances of metabolism.

mparison of Diabetes in Fat and Lean Depancreatised Dogs.

The differences in the course of pancreatic diabetes
lean and fattened dogs are very striking; the most
portant are as follows:

Fat animals.	*Lean animals.*
Death usually occurs about fifth day, preceded by mptoms of vomiting, coma, anhydræmia.	Animals may live for over a month. Vomiting may appear about fifth day, but animals usually recover.
After coma appears, treatnt with insulin sometimes s to prevent death.	Symptoms very readily removed by insulin.
Hyperglycæmia very marked.	Hyperglycæmia moderate.
Ketonæmia marked.	Ketonæmia not so marked.
D : N ratio after third day ally above 3·65.	D : N ratio much lower and may be well below 2 by the second week.

The diabetes is in every regard far more acute in
fattened animal, and the relatively more marked
perglycæmia as well as the higher D : N ratios
ongly suggest that fat must be a source of some of
sugar. This hypothesis is also supported by the
owing observations:

. The D : N ratio on the fifth day in fattened
ancreatised dogs often exceeds 5 : 1 after making
wance for the glucose which might theoretically
derived from the glycogen stores of the liver and
scles (cf. Chaikoff [18]).

. Repeated injection of epinephrin may cause
siderably more extra glucose to be excreted than
be accounted for after making allowance for that
ivable from glycogen and protein (Chaikoff and
ber [19]).

. Excessive ingestion of fat may cause an excretion
extra glucose which exceeds that derivable from
ogen and protein (Soskin [20]).

have discussed elsewhere the further evidence
ch indicates that gluconeogenesis is not restricted
rotein (Macleod [21] and Macleod and Gottschalk [22]),
will only add here that the two criteria upon
ch the denial of this hypothesis rests—namely,
constancy of the D : N ratio and of the respiratory
tient in completely diabetic animals are definitely
wn by our researches to be unsound. These
os are undoubtedly constant under strictly
dardised conditions in animals poisoned by
rhidzin, but this is not true diabetes, since insulin
ill available in the body of the animal. Finally,
hould be pointed out that the conclusion that fat
form sugar in the animal body is also supported
umerous clinical observations on diabetes mellitus,
ch have been admirably summed up by
muyden.[23]

THE MEDICAL TREATMENT OF CANCER.*

By A. T. Todd, M.B. Edin., M.R.C.P. Lond.,
HON. ASSISTANT PHYSICIAN TO THE BRISTOL ROYAL INFIRMARY.

Although there is no medical treatment of cancer at present, or no medical system which will ensure regression of malignant growths in a high percentage of cases, the title of this lecture was chosen deliberately. It was hoped that the surgeon might be impressed from the outset with the fact that medical or medicinal treatment may really be of value.

The attitude of the medical profession to cancer is rather peculiar; it is, perhaps, the only disease, as differentiated from malformation or injury, which has been handed over to the surgeon without reserve. Physicians explain this by saying that medical treatment is ineffective, and is likely to be so until the cause is known, when some vaccine or serum therapy may become possible. This attitude is rather deplorable, for though the cause of cancer may be discovered, it is quite likely that the discovery may not help much more than the discovery of Koch's bacillus has helped the treatment of tuberculosis. A comparison of cancer as a disease with tuberculosis is justifiable; there are some strong similarities. Sixty years ago tuberculosis was regarded by some as probably neoplastic, and there were almost as many theories as to its cause and so-called types as there are for cancer now. We know the cause of tuberculosis now, and can reproduce the disease; but most of us have stopped trying to treat the disease; we treat the patient instead, to his benefit. Cancer may turn out to be similar; we have been treating the disease as intensively as possible, and the results are well known. May it not be well to follow the programme of other chronic diseases, and try treating the patient? May he not have the disease because of some metabolic or other abnormality of which the relationship is obscure at present?

Lead Selenide.

This research was commenced in 1925, shortly after the revival, or rehabilitation, of the lead treatment of cancer was brought about at Liverpool. Lead is an old remedy for cancer; Ambroise Paré used it with success, and we (the plural used to include the team) have obtained some results from a modification of his method.[1] As there had been signs of promise from selenium in cancer, it was considered that the union of lead with selenium might give better results than lead alone. A colloidal lead selenide was made and, after careful testing on

* A lecture and demonstration of cases delivered to the British Association of Surgeons at Bristol, on May 2nd, 1930.

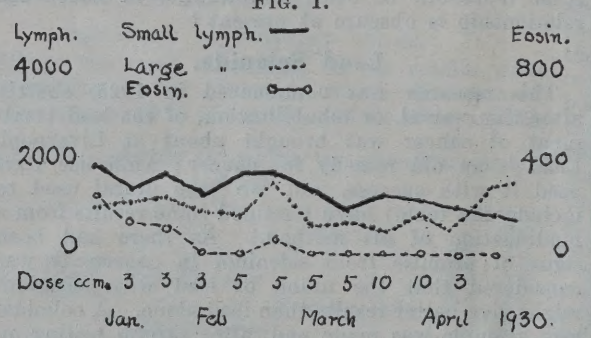
animals, used for man. Fortune was kind to us, for our first few cases happened to be more than usually susceptible to this treatment; thus we were encouraged to continue.

A new method is often successful at the start. Trousseau said: "Let us make haste to use this remedy while yet it cures." In order not to be misled, we made the test as difficult as we could; we accepted for treatment only advanced and completely inoperable cases. The only choice of cases was certification that nothing could be done, and that the patient was not actually moribund. A leader in experimental medicine said, when this programme was outlined to him, that if we were successful in 1 per cent. of cases we would have done much; we can definitely show more than that. But if I am asked for exact percentages and statistics I am unable to give them. It is impossible to give percentages on about 100 cases, for though we have treated more than this, for various reasons, only about 100 are worthy of scrutiny. Moreover, how shall we warp statistics to show relief of pain, prolongation of life and, more important—the gratification of the patient given hope and action instead of a passive expectancy of death?

We do not expect to cure the cases we have chosen to treat. The late advanced case, riddled with metastases and often with involvement of vital structures is not the type of case on which to base encouraging statistics. Even though the cancer were removed, the cicatrisation of repair would probably kill more quickly than the cancer. We chose these cases to demonstrate the utility, or otherwise, of this treatment in producing relief of pain, euphoria of the patient and regression of the cancer; then, when a technique was learned, we should hope to apply the method to earlier cases, with less widely spread growth, and therefore some hope of survival. There are several valuable monetary prizes for the discoverer of a cure for cancer, but it is

FIG. 1.



Leucocyte count, absolute, of non-reactive case. Alteration of the dose did not affect the leucocytes.

probable that these prizes will never be awarded; though the cancer may be got rid of, the patient dies. We have records of a tolerable number of cases of widely spread cancer treated by this method in which at autopsy little or no growth was found. Until diagnostic methods have improved to the degree at which late cancer is a rarity, there is no point in attempting more; for, though a remedy more active than ours is found, it could not be accepted as a cure, for these late cases would die the quicker from its use.

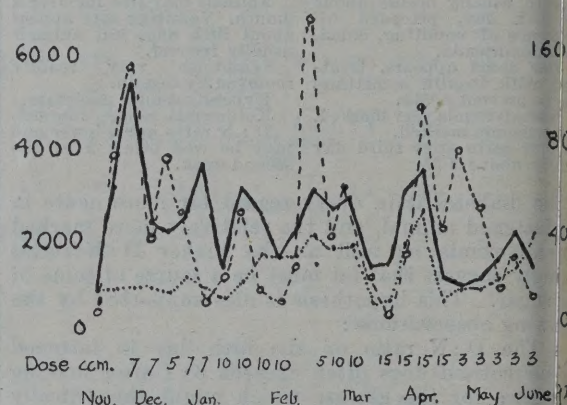
To give a brief example; a patient with a large, bleeding, sarcoma of the lower dorsal spine was one of the first treated. We gave a large first dose, and were gratified to see the bleeding stop and the mass shrink. About a week later we doubled the dose, and the visible mass became gangrenous. As it extended into the peritoneum, the patient died; at the autopsy only one or two small masses had escaped gangr —i.e., the remedy was excellent, but the patient died of

Throughout this research our programme has be to develop a technique with the hopeless cases, th apply the method as an addition to the pres surgical and radiological treatments.

THE PREPARATION USED.

As the technique of the treatment has been pu lished,[2] only a brief summary need be given he The preparation we use is available to all, bein

FIG. 2.



Leucocyte count of reactive case. The lines and figures have same significance as in Fig. 1.

0·4 per cent. sol of lead selenide, manufactured by British Drug Houses, Ltd. It is labelled D4S, and no profit from the sale of colloid or of the monograph is made by any member of this research team. No patient, though some have been wealthy, has been allowed to pay any fee for treatment. I have been asked why one firm is allowed a monopoly; the reason is that we were able to teach one firm the very exact method necessary to produce a non-toxic colloid; we could not hope to publish a description accurate enough for any chemical manufacturer to use.

The colloid is of low toxicity when made in the proper manner; a rabbit will tolerate 4 c.cm. per kilogramme. It is not possible to state the lethal dose for an adult human, but as much as 33 c.cm. has been given in one dose without adverse effects. The toxicity does not appear to depend upon the colloid directly; adverse effects, such as temporary increase of pain around the neoplasm and pain at the sacrum appear to be proportional to the amount of action on the neoplasm. These reactive effects are considered to be due to protein poisoning from breakdown of cancer tissue. Symptoms of toxic action of lead are unusual, colic is seldom observed. Immediate shock-like reactions are seen occasionally; they are similar to the crises observed after injection of preparations of any of the heavy metals. These immediate crises are readily prevented by administration of ephedrine hydrochloride and adrenalin just before the injection.

DOSAGE.

The size of the initial dose depends upon the nature of the neoplasm. From our experience we divide neoplasms into two classes:—

1. Likely to be *resistant:* squamous carcinoma of tongue, vulva, skin generally; adenocarcinoma of breast; carcinoma of cervix; carcinoma of rectum. For these an initial dose of 5 c.cm. is given.

2. Likely to be *sensitive:* any neoplasm which has recently been radiated with gamma rays; sarcoma; endothelioma; carcinoma of ovary; hypernephroma;

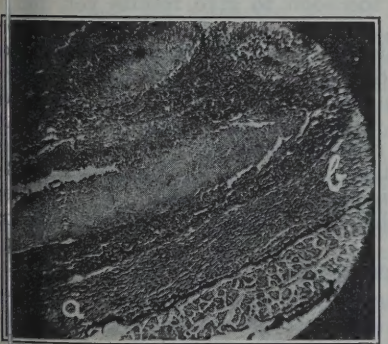
imary or secondary carcinoma of liver or kidney. For ese an initial dose of 1 c.cm. is given.

We give the colloid intravenously at weekly intervals. The size of the later injections depends upon ie amount of focal and general reaction, for this, s was said above, appears to be proportionate to ie amount of action on the neoplasm. A definite, ppreciable reaction is desired, it should last for about 4 hours and comes on from 6 to 48 hours after the njection; the time of onset of reaction varies from atient to patient, but is fairly constant for a single atient. When the reaction has passed there is sually a feeling of well-being with increase of appetite nd diminution of pain; some of the patients describe as a tonic action. We increase the size of the jection by 1 or 2 c.cm. in sensitive neoplasms, and to 4 c.cm. in non-sensitive neoplasms, until we find e maximum dose which is followed by a satisfactory inical and hæmatological reaction; that dose is then aintained. We claim that the treatment has a vourable action in the majority of the cases; it is timated that in about one-fifth of the patients there no appreciable result, but in the remainder more or ss improvement is found to follow.† If the treatent is given haphazard and in large injections there ll be only unfavourable results. We tried maximal ses for a time, that is, we gave the patients as much they would stand; the result appeared to be an crease in the rate of growth of the cancer. Too nall doses might have the same effect. We claim at the treatment is good, but the explanation of action is not yet proved.

THE REMEDIAL EFFECT.

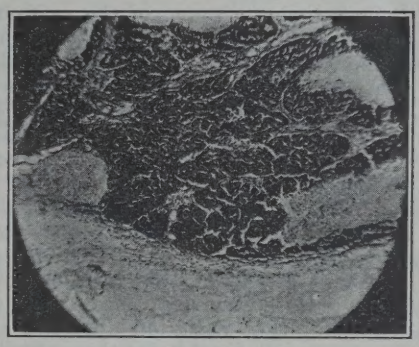
As with all new remedies a specific, or immediate, tion on the cancer cell was considered to be the planation. The Liverpool school pointed out certain resemblances in the cells of certain neoplasms to certain cells of the decidua, and correlated the known abortifacient action of lead on the decidua with this. They considered that the preparation of lead which they used was taken up by the cancer cell and the ested lead occasioned the death of the cell. This ory was not accepted in Bristol, for we found that more of this supposed cancer cell poison we gave, quicker was the growth of the cancer; then ue analyses always showed that there was less tal lead in the cancer than was found in the normal ues. Since every so-called specific remedy is nd later to have an indirect action, we considered t lead selenide would also act indirectly. Examination of the blood, originally undertaken to guard against anæmia and other toxic manifestations, showed that there was a definite sequence of changes after injection. In the cases which showed response we found that the small lymphocytes and eosinophil leucocytes of the blood showed an increase; while in cases which did not respond this blood change was not observed (Figs. 1 and 2). In addition, we found that the normal fat-splitting enzyme of the blood, which was usually increased in late cancer, showed a diminution when the treatment was being effective.

FIG. 3.



ort adenocarcinoma. Junction tissue appears as a well-marked belt **a—b**. The same amount of metal lead (but as guaiacolate, not selenide) and radium as in Fig. 4. Necrosis of the superjacent cancer is almost complete.

FIG. 4.



Twort adenocarcinoma. Absence of junction tissue, presumably from gamma radiation after selenide. Necrosis of cancer is trivial. Cf. Fig. 3.

It would take a long time to go into the many possibilities and give explanations as to what these cell changes might signify; to condense, it is considered that lead selenide is a stimulus to the defence which is put up against the irritation or invasion of a malignant neoplasm. The cellular defence, if it exists, is familiar to the pathologist as a more or less imperfect barrier of lymphoid and plasma cells, fibroblasts, eosinophil and basophil cells, and that endothelial cell which has many names, but is best called the macrophage. In slowly growing cancers this surrounding, or junction tissue, is abundant, and it is conceivable that it is a barrier; in rapidly growing cancer the junction tissue is scanty, and perhaps this is the reason for the rapidity of growth. On the other hand, it can be argued that the poverty in junction tissue in rapidly growing neoplasms is due to the lack of time for junction tissue to develop.

We have fairly definite evidence that this treatment increases the lymphocytes, plasma cells and eosinophil leucocyte of the blood. We know that any electro-negative colloid, of which D48 is one, will tend to increase the activity of the macrophages. We find that hyperplasia of fibrous tissue frequently follows to an embarrassing degree, for in cases of extensive cancerisation of the peritoneum, this fibrous hyperplasia often kills the patient from stenosis of ureter or intestine. Though we do not say that the cells of the junction tissue are derived from the cells of the blood stream, and that increase of lymphoid cells in the blood will be followed by an increase round the neoplasms, yet the stimulus which causes increase in the one place might be expected to cause an increase in the other.

Chemotherapy plus Irradiation.

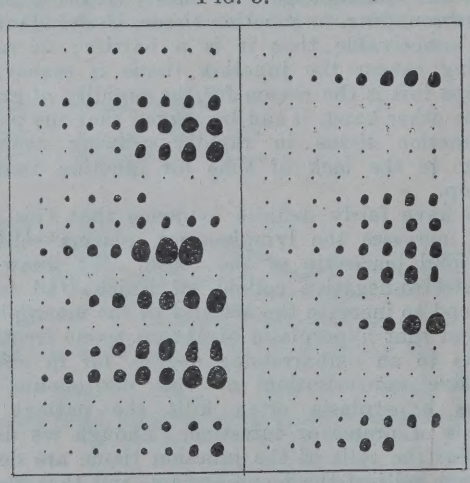
This conception of our treatment, being a stimulus to the defensive action of the junction tissue in addition to any possible stimulation of general defence mechanisms, is of importance with regard to combination of such chemotherapeutic agents and radiotherapy. We find that radium treatment of implanted mouse cancer, the Twort adenocarcinoma, appears to cause an increase of this junction tissue, and we are inclined

†This estimate is made from the whole of this series; if id comprised mainly carcinoma of lip and tongue, or other tant types, more than one-fifth would be found nononsive.

to think that the regressing action of gamma rays in vivo is due to stimulation of this junction tissue, rather than to direct noxious action on the cancer cell. The plates show that where junction tissue is plentiful and well formed the proximal cancer cells are necrosed, wholly or in part. Where junction tissue is scanty or absent the cancer shows no necrosis, even though the dosage of radium was kept constant (Figs. 3 and 4). Since, then, radiation and some lead compounds both increase this mesoblastic defence tissue, a union of the two ought to be more potent than either singly. Though proof of this opinion is not complete, we have evidence supporting it in man and in animals, and I have verbal accounts of some encouraging results from other centres.

Our early efforts to combine radiation with lead selenide were unfortunate. A record has been published,[3] and full details are not necessary here. In brief, we found that the application of half carcinoma doses of radium, radon, or X rays shortly after treatment with lead selenide was followed by a prompt increase of the rate of growth of the neoplasm; this was one reason for considering the possibility that radiation does not act primarily on the cancer cell, for if it did there should not have been increased growth. We know that there is a stimulating dose for cancer, but this is regarded as considerably less than half the accepted dose. When 12 cases had been radiated after injection of lead selenide, and the stimulation was observed in each case, we stopped this in man and continued the research on animals. We found that the result was the same in implanted cancer; radium applied in usual dosage soon after selenide injection resulted in larger growths and more rapid death than was found in the untreated control animals. We have reason to believe that it is the selenium which is responsible

FIG. 5.

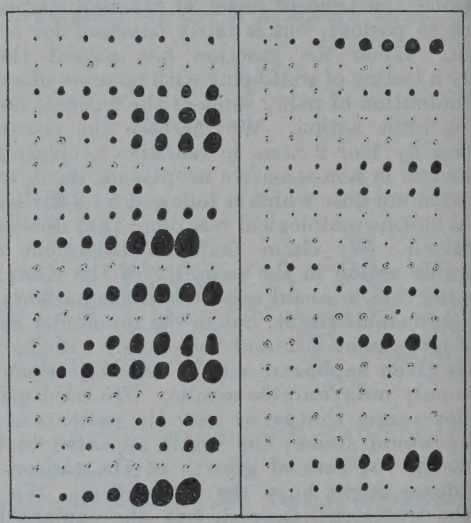


Twort adenocarcinoma treated by oral administration of pure vitamin A. Controls left; treated animals right. Each horizontal line is composed of the silhouette of the cancer at weekly intervals. The size is reduced about ten times.

for this, for a colloidal lead guaiacolate could be administered before irradiation without this adverse result. Fig. 3 showing well-formed junction tissue and necrosed cancer is from a mouse treated with lead guaiacolate and then radiated. Fig. 4 showing the reverse is from a mouse receiving lead selenide and then radium; both sets were given exactly the same amount of lead metal and radium. The explanation appears to be as follows:

The members of the selenium group of metalloids are peculiar inasmuch as they are ionised by deep X and by gamma rays. We have proof for sulphur, which is nearly related to selenium that laws for the one will h for the other, that diminution of the size of the particle followed by increase of toxicity; this would follow, t smaller the particles the larger would be the surface availa for chemical action. We picture the selenide taken by the macrophages and possibly the fibroblasts around cancer in the junction tissue; here the colloid is sometim visible as relatively large clumps in the cytoplasm. Wh

FIG. 6.



Twort adenocarcinoma treated by oral administration of vitamin D. Controls left, treated animals right, as in Fig.

gamma rays reach it some or all of this mass is ionised, toxicity is increased, and the cell containing it is destro When a non-ionisable colloid, such as the guaiacolate is used this cell destruction does not follow.

We, and others, are attempting to work ou technique for radiation therapy concurrently wh selenide. It is too soon to give results yet, but this laboratory, and at least one other, there h been results which give promise of this combinat being useful. Such a combination would req less radiation and less selenide. For the present are careful not to subject to radiation any pati who has been recently treated with selenide. ask for any radiation to be given first, in the h that this will increase the junction tissue and function, and that the selenide will cause a furt increase.

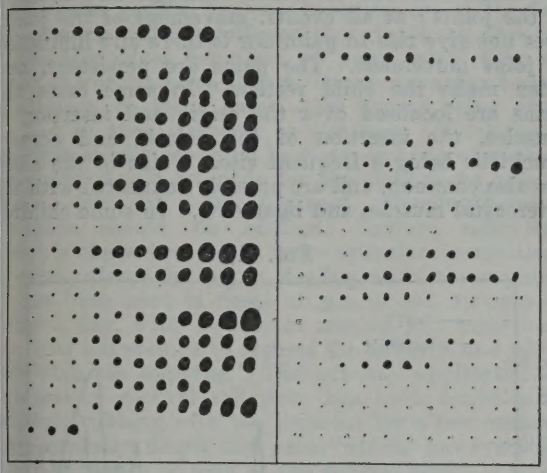
Additional Treatment.

The remaining part of the treatment we use n not detain us so long, but its importance is not the for this. In view of the known fact that lead te to be stored in the bones as a compound lead-calc phosphate, we considered that the patients ought to be treated with any substance likely to dimi this storage; otherwise any condition associated v acidosis would occasion a liberation of unkn amounts of ionic lead from the skeleton and cause poisoning. The obvious remedy was calcium chlor for this would not only cause enough acid shift in plasma to prevent much bony deposit of lead, bu would also give the organism a sufficient depô calcium for any depletion of the skeleton.

In addition, we know that cancer tissue and the pla of cancer patients show a poverty of calcium. The pov of calcium is proportional to the rapidity of growth o cancer; the more virulent and advanced the growth less is the calcium content of cancer and plasma; perio sarcoma appears to be an exception. Moreover, researches on the acid-base equilibrium of cancer pat and animals show that in precancerous states and in ca before cachexia has developed, the patient is alkalot

kalosis is accompanied by a diminution of ionised, or tive, calcium. Calcium chloride, though a neutral salt, uses acidosis by relinquishing hydrochloric acid in the kaline intestine, the calcium becoming carbonated from aste gases. Calcium chloride would appear to be indicated it would correct the alkalotic shift and thereby increase e diminished calcium, while at the same time it would ave a depôt of calcium for absorption. Our patients all ceive 3 g. of calcium chloride daily; this is given as an buminate, and the formula is published.[5]

FIG. 7.



wort adenocarcinoma treated by weekly intravenous injection of lead selenide. Controls left. Note slow rate of growth of controls and much slower growth of the treated animals.

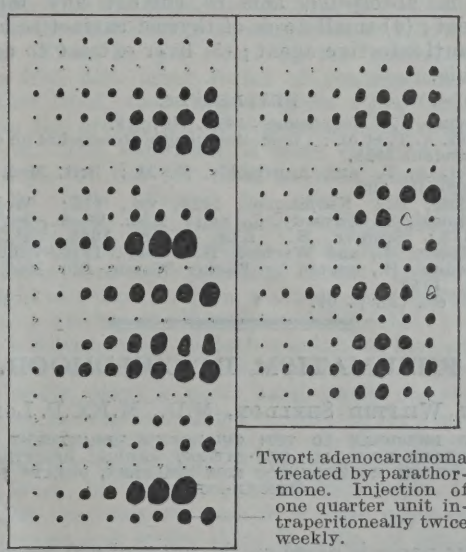
In the hope of increasing the assimilation of calcium, e started giving our patients the fat-soluble vitamins bout a year ago. The fat-soluble vitamins, in ddition to having this remineralising action, are aid, at the present time, to have an anti-infective ction. It would take too long to consider the roblem of cancer as an infective disease, and though any would not subscribe to this belief at present, ow will deny that the advanced cases we treat are condarily infected. The fat-soluble vitamins ould be of help in combating this septic factor. he evidence in the literature is very conflicting as the value of vitamin medication in cancer; the eason may be the different concentrations and ixtures employed by various workers. We have one a good deal of experimentation with vitamin eding of mice with implanted cancer and we can ay, with some assurance, that Ostelin, pure itamin A and pure D all diminish the growth of wort carcinoma. Pure vitamin D, especially, is arkedly inhibitory, the retardation and regression f the implant which follows its ingestion is quite s marked as that of treatment with lead selenide Figs. 5, 6 and 7).‡ Owing to the generosity of the ritish Drug Houses we have been able to treat our uman cases with very large doses of vitamin D of ite; it appears to be really useful when the amount f oily solvent can be tolerated. One instructive ase is worth a brief description here:

About a year ago I was asked to see a patient who had eveloped acute pain in the right chest. A radiogram owed a large solid mass. A little later two nodules appeared in the subcutaneous tissues of the left chest wall. A few days afterwards his right eye became paralysed. On examination I found a complete ophthalmoplegia of the eye, a solid right base, two large masses in the left chest wall and spastic diplegia of the legs. I concluded that this was probably sarcomatosis, and advised excision of one of the superficial masses; this was found to be a polymorph-celled sarcoma, and this diagnosis has been confirmed by several authorities. In view of the rapidity of the symptoms in this case and the scarcity of beds, I advised the patient's doctor that it would be well to wait and watch the rate of growth; if the latter was not so rapid as we thought we would attempt treatment. The patient was advised to rest and to eat as much spinach as possible, and as he had an unlimited supply he ate a great deal. The remaining superficial mass rapidly disappeared, the right base became resonant again and X rays showed no opacity, his diplegia passed off. A few weeks later he came to see me. Then he was able to do what he wanted, which was to go to as many race meetings as possible; provided he covered his lamé eye, he felt very well. This man had no treatment but spinach, a vegetable especially rich in vitamin A and in carotene. His recovery may have been coincidence, but in view of our animal results I am inclined to attribute it to vitamin A. It should be pointed out that after about six months he had a relapse and died.

Besides the fat-soluble vitamins, parathyroid extract increases the calcium of the plasma and tissues. We have observed the effect of this in animals; given by the mouth it appears to have no action. Collip's parathormone, given by injection, however, appears to have a definite retarding action in mice implanted with Twort carcinoma (Fig. 8).

Thyroid extract, a true tonic by virtue of its action in stimulating metabolism and immunity processes, has a place in the treatment of cancer. We usually give a small daily dose. Finally, to combat the anæmia usually present in advanced cancer and the anæmia occasioned by prolonged injection of lead compounds, we give the patients liver extract. Again

FIG. 8.



Twort adenocarcinoma treated by parathormone. Injection of one quarter unit intraperitoneally twice weekly.

we have experimental evidence that animals with implanted cancer do better if given liver extract. We give a daily dose corresponding to four ounces of liver.

Conclusions.

This is, in outline, the treatment we give our patients, and the reasons for giving it. We do not advise anyone to adhere to our programme; we must, for we are in hopes of finding a better treatment. But the method, as we practise it on advanced cases, will probably not reduce the mortality of cancer appreciably. We hope that the surgeon will reduce

‡ The implanted cancer noted here in the animal experiments Twort adenocarcinoma from the Imperial Cancer Research und. We use solely a very slowly growing strain, for the ore rapid strains do not allow sufficient time to observe ie effects of this treatment. This slow strain is maintained y implanting from small, slowly growing tumours. Selenide eatment of rapidly growing implanted cancer has given rela- vely poor results in this laboratory, nothing like the results gured here. The rate of growth can be inferred from the gures; charting commences about four weeks after implanta- on and thence at weekly intervals.

this mortality by applying this method in association with the present surgical procedures:

1. Until we, or others, have found a method for the concurrent treatment by radiation and selenide, to treat such cancers as are likely to be influenced with radiation first, and as thoroughly as possible. After radiation is over and the patient has had time to recover, to treat by this method.

2. In inoperable cancer to remove as much as possible by surgical means and afterwards to try to make the remainder regress with selenide. It seems logical to expect a better, and easier, result when most of the mass has been removed. In cases of cancer with metastases in liver or kidney it will be well to remove the primary growth, for the metastases in liver and kidney appear to require small doses of colloid and do badly on the larger doses required by their primary growths.

3. Especially we advise giving the treatment after operations which are regarded as having been complete. In an unknown percentage of the cases completion has not been achieved and recurrence follows. Since reaction, and adverse effects of the treatment largely depend upon the amount of destruction of the cancer, these cases should and do react little, and the treatment is little hardship.

Finally, we strongly advise that the whole of the method is used; we cannot be sure how much the interaction of the various medicaments conduces to the results we get. That is, we advise that the patient be given: (1) lead selenide to increase local and general defence mechanisms; (2) calcium chloride to increase ionised calcium by acidosis, to correct alkalosis, and to furnish a depot for calcium assimilation; (3) fat-soluble vitamins in large doses, especially vitamin D as Radiostoleum or pure D, to increase calcium absorption and to combat any infective element; (4) small doses of thyroid extract as a tonic and anti-infective agent; (5) liver extract to combat anæmia.

RHEUMATISM IN CHILDHOOD.

BY WILFRID SHELDON, M.D., M.R.C.P. LOND.,

JUNIOR PHYSICIAN TO THE CHILDREN'S DEPARTMENT, KING'S COLLEGE HOSPITAL; OUT-PATIENT MEDICAL REGISTRAR, THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

THIS paper is based on the notes of 600 consecutive cases of rheumatism seen during the last two years at the rheumatic clinic of the Hospital for Sick Children, Great Ormond-street. Many were under observation during the whole of this period.

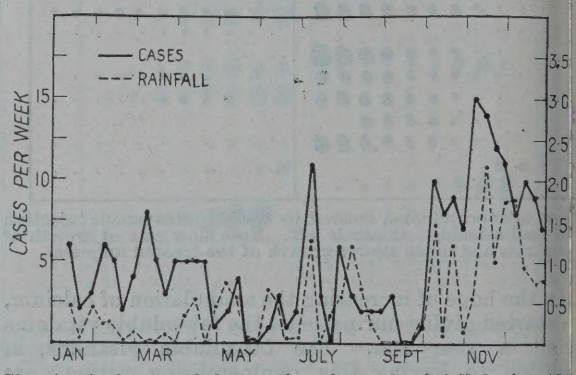
The children can conveniently be divided into four groups: (1) those with rheumatic pains in the limbs (235); (2) those with a history of rheumatic fever or acute articular rheumatism (133); (3) those with chorea (197); (4) those with rheumatic heart disease (266).

Rheumatic Pains.

Children who complain of recurring pains in the limbs form an important group in a rheumatic clinic because of the possibility that some of them ma later on develop heart disease. The joint pains tha occur with rheumatic fever are not included in th group.

Rheumatic pains are seldom met with before th age of 3 years. Although most common in the leg they also occur in the arms, over the shoulders, an round the neck. Usually they can be localised b the child to some definite area of the limb, often i the neighbourhood of joints although not actuall in the joints; at all events, movement of the join does not give rise to pain, nor is there any limitatio of joint movement. The pains are persistent, an often make the child restless. In some cases th pains are localised over the origin and insertion muscles, the insertion of the deltoid and corac brachialis being a frequent site. Pains in the che are also common, and are possibly connected with th intercostal muscles and ligaments. In some childre

FIG. 1.



Showing incidence of rheumatic pains and rainfall during 19

the pains seem to be particularly frequent at nig soon after the child has got into bed; such night pai can often be eliminated by putting the child to sle between blankets. Pains that occur during the d are as frequent in the morning as in the evenin and are not related to fatigue.

There seems little doubt that the incidence rheumatic pains bears some relation to cold and w weather. In Fig. 1 the continuous line represen the number of children per week who complained pains in the limbs while attending the rheumat clinic at Great Ormond-street during 1929. The brok line represents the weekly measurements of rainf in inches recorded at Camden-square, N.W., duri the same period. For these latter figures I a indebted to the British Rainfall Association. The is sufficient parallelism between the two lines justify further investigation into this aspect rheumatism. A discrepancy between the lines obvious in March when, although rain fell on one d only, the incidence of rheumatic pains remain practically constant. Following upon a fairly d May and June, the first week of July was very w and complaints of limb pains were then numerou September was a month of drought, and there we practically no complaints of pains. The droug terminated in the first week of October, and with t fall of rain complaints of pains were resumed.

The pathological process concerned in the producti of rheumatic pains is uncertain, and the evidence f regarding them as rheumatic rests on their clinic association with other manifestations of rheumatis In 52 out of 266 children with rheumatic heart diseas pains in the limbs over several months was the on evidence of rheumatism that preceded the discove

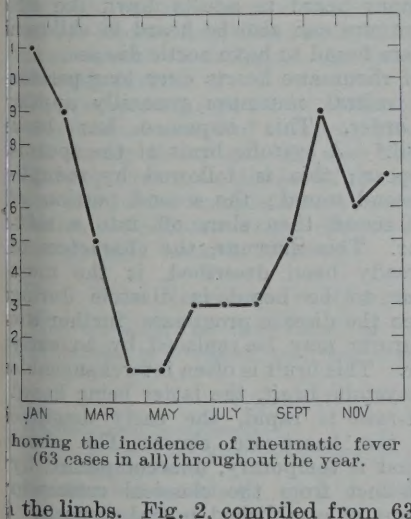
f the heart lesion. A history of pains in the limbs receded 15 out of 197 cases of chorea. The common mpression that these pains afford early evidence of heumatic infection is borne out by these figures. t is unusual for the reverse to happen—namely, that ains in the limbs should be a late symptom of heumatism, appearing for the first time several ionths or years after a child has shown other signs f rheumatic infection.

In the treatment of children suffering from rheuatic pains general hygienic measures are of the first mportance. It is significant that rheumatic children ractically never complain of pains while they are way at a convalescent home. Damp, draughty houses redispose to these pains, new houses being often s bad in these respects as old ones. Thick boots nd long stockings should be worn, and in wet weather rovision should be made for the child to be able to hange into dry shoes at school. Sleeping between lankets should be advised. Sodium salicylate, hich is of great service in acute articular rheumatism, often disappointing in dealing with these pains. t has been used in doses of grs. 5 and 10 once or wice a day, with inconstant results, and sometimes he drug has seemed to depress the children and interre with the appetite. The external application of niment of methyl salicylate has been found more elpful; rubbing with the liniment for a few minutes ill generally dispel the pains which, however, are kely to return so long as the general health remains nimproved. For this purpose a period of conalescence and the judicious use of a suitable tonic, uch as equal parts of the syrup of the iodide of iron nd malt, are often of value.

Rheumatic Fever.

In common with the other rheumatic manifestations, heumatic fever, or acute articular rheumatism, is rarely encountered before the age of 3 years. Out of 133 instances of acute articular rheumatism, the youngest example occurred in a child 2½ years old, and three cases developed at the age of 3 years. Rheumatic fever is particularly likely to occur during the cold and wet months, being in this respect similar to rheumatic pains in the limbs. Fig. 2, compiled from 63 cases of rheuatic fever, gives the number of cases occurring in ach month of the year, and shows how the incidence f the condition falls off during the summer months.

FIG. 2.



howing the incidence of rheumatic fever (63 cases in all) throughout the year.

A feature of rheumatic infection, no matter what inical form it takes, is the inability of the patient to stablish a lasting immunity after one attack. Of he 133 cases now under discussion, 21 experienced a econd attack and two had three attacks. The shortest nterval between any two attacks was six months.

The symptoms of rheumatic fever are often milder in childhood than in adults, and the classical description of painful swollen red joints, one joint being affected after another, is not always seen. The affected joint is invariably painful, but swelling is not always evident, while a red flush over the joint is less common than swelling. Occasionally only one joint is affected.

The relation between rheumatic fever and heart disease is too well recognised to need discussion. Coombs [1] has recently stated that every child with rheumatic polyarthritis may be assumed to have an infected heart also, although clinical evidence of the heart affection may not always be found. Of the 133 cases of rheumatic fever at the clinic at the Hospital for Sick Children, 93 (70 per cent.) showed evidence afterwards of cardiac involvement. Of the remainder, rheumatic fever was followed by chorea in five cases, and by pains in the limbs in 12 cases. Only 23 children (17 per cent.) have been entirely free of rheumatic symptoms since their attack of rheumatic fever. These figures illustrate the necessity of keeping under observation for some time children who have once had rheumatic fever. The supervision of these children should be one of the functions of a rheumatic clinic.

Chorea.

The age incidence of chorea begins a little later than the other manifestations of rheumatism, being uncommon before the age of 5 years, when schooling begins. Poynton [2] has recorded an example of rheumatic chorea in a baby of 10 months. Sydenham's chorea is so often associated with other forms of rheumatism that it is now generally accepted as a rheumatic manifestation. Of 197 cases of chorea at the rheumatic clinic at Great Ormond-street rheumatic heart disease occurred in 52, rheumatic fever preceded five cases, and in 15 instances rheumatic pains in the limbs either accompanied or followed the chorea. Thus 36 per cent. of the children with chorea had also other forms of rheumatism. On the other hand, there appear to be other factors at work in the production of chorea besides rheumatic infection. The condition is more common in girls than boys—of the 197 children with chorea, there were 2·1 girls affected for every boy—whereas rheumatic fever and rheumatic carditis are evenly distributed between the sexes. The onset of chorea often dates from some psychical shock. In one child the fright of a thunderstorm was sufficient to start the chorea; a caning at school preceded another; minor street accidents seem to be becoming an increasingly common forerunner. The mental stress of education undoubtedly plays a part, particularly competitive education such as is entailed in working for a scholarship. Children who are apt to develop chorea are almost always quick and intelligent and keen on their school work, but for the sake of their health it is a pity that they cannot work in a class where marks do not exist and where there is neither a top nor a bottom place. I have endeavoured to obtain figures showing the effect of schooling upon the production of first and later attacks of chorea, but this has proved impracticable. In this connexion the school medical service should be able to gather valuable information.

TABLE I.

Children attending clinic after—			
1st attack of chorea ..	142	4th attack of chorea ..	3
2nd ,, ,, ,, ..	40	5th ,, ,, ,, ...	1
3rd ,, ,, ,, ..	9	6th ,, ,, ,, ...	2

Chorea is very likely to relapse. From Table I. it may be seen that one or more relapses occurred in 28 per cent. of 197 children.

TREATMENT.

There is little doubt that, in the treatment of acute chorea, rest in bed is the most important factor. Difficulty arises when the choreic child has recovered sufficiently to return home. When should the child go back to school? Here no general rule can be laid down. At the clinic at the Hospital for Sick Children the average time that children with chorea have been exempt from school has been six months. This has seemed unnecessarily long in some cases, while others have relapsed on returning to school after an absence of 12 months. The home circumstances must influence the decision. If absence from school implies that the child will spend most of the day in the street dodging traffic it is better for that child to return to school early. When there is a garden and the mother or some other responsible person is at home all day, six months away from school should be a minimum. A stay at a convalescent home is valuable, particularly if a mild amount of education can be combined with the convalescence. In many cases half-day attendance at school for two or three months before allowing whole-day attendance has proved useful. Once a choreic child returns to school he soon makes up the ground lost through absence. Close coöperation with the school medical service and the education authorities is essential in the management of these children.

Rheumatic Heart Disease.

Of the 600 children with rheumatism whose notes have been analysed, 266 were found to have heart disease—a percentage of 44. Table II. summarises the evidence of rheumatic infection being present before the onset of heart disease.

TABLE II.

	Cases.
Acute articular rheumatism preceded carditis in ..	87
Chorea preceded carditis in	52
Recurrent pains in the limbs preceded carditis in	52
Tonsillitis—no other symptoms—preceded carditis in	7
Carditis dating from scarlet fever	10
Carditis dating from diphtheria	4
Carditis dating from tonsillectomy	2
Insidious—no preceding rheumatic history	36

The group in this Table to which I wish to allude is the last—the 36 cases of insidious heart disease. In these a careful inquiry into the child's history failed to reveal any item suggestive of rheumatism. Unfortunately, the rheumatic process seems to be none the less destructive for being insidious in onset. Of the 36 children only one has recovered. This was a boy who was found to have a dilated heart with an apical systolic bruit; 18 months later the heart became normal. Four children of this group first attended with systolic and mid-diastolic apical murmurs; the mid-diastolic element has now gone, although the systolic murmur persists. Of the remainder, 24 have a well-marked mitral systolic murmur and four of these are certainly proceeding to stenosis. One boy has aortic regurgitation, while of six children who have attended with mitral stenosis of insidious origin two have died. Rheumatic heart disease coming on insidiously tends to run a slowly progressive course, which it is difficult to influence by therapeutic measures.

The early diagnosis of rheumatic heart disease may sometimes offer considerable difficulty when a child has a soft systolic bruit at the apex, but the heart is not enlarged. In many of these the bruit is temporary and disappears when the general health improves. A history of acute rheumatism or chorea suggests that the bruit is organic. Organic systolic murmurs are often more easily heard when the child is lying down or lying on his left side than when he is standing up. They also show little variation with inspiration and expiration. Such cases as these, in which the diagnosis of rheumatic disease of the heart is in doubt, may with advantage be supervised in a rheumatic clinic for a few months, until the significance of the bruit has been determined.

The presence of a murmur at the apex during diastole is a valuable sign of organic disease. The most common murmur to be heard during this period is a mid-diastolic murmur, and this often enables one to be sure that a systolic bruit is organic. In order to hear a mid-diastolic murmur it is generally necessary to have the child lying down. The murmur is separated from the second sound by a short interval, giving rise to three sounds at the apex—a systolic murmur, then the second sound, followed by the mid-diastolic murmur. Its point of maximum intensity is a little internal to the apex-beat, and it is very localised, seldom covering an area more than an inch or an inch and a half in diameter. The following case throws some light on the way in which this murmur is produced:—

A girl, aged 5, was sent to the rheumatic clinic on account of heart disease. She was found to have complete heart block, the ventricular rate being 44 per minute, while the auricle was beating at 80 per minute. In addition to a systolic murmur at the base of the heart, there were systolic and mid-diastolic murmurs at the apex. The mid-diastolic murmur occurred 44 times each minute, which indicated that it was produced by the action of the ventricle rather than by that of the auricle.

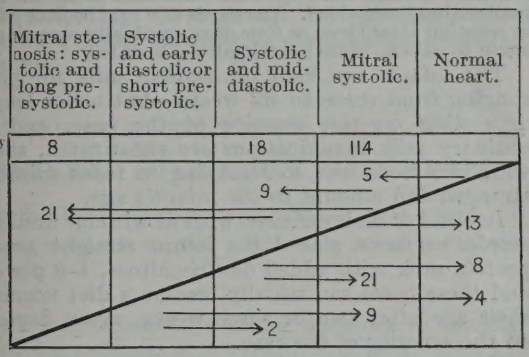
It seems likely that the murmur is due to the ventricle sucking blood from the auricle during diastole through a thickened or stiffening mitral valve. Sutherland[3] has expressed the view that the diastolic murmurs at the apex in rheumatic heart disease originate from the aortic valve, but there is little to support this. Other evidence of aortic disease, such as Corrigan's pulse and a big pulse pressure, is wanting; moreover, the typical aortic regurgitant murmur heard in adults down the left border of the sternum can also be heard in children who at autopsy are found to have aortic disease.

Observation of rheumatic hearts over long periods shows that the mitral murmurs generally appear in a definite order. This sequence has been described by Still.[4] A systolic bruit at the apex is the first to appear; this is followed by reduplication of the second sound; the second portion of the reduplicated sound then slurs off into a mid-diastolic murmur. This murmur, the characters of which have already been described, is the most common murmur to be heard in diastole during childhood. When the disease progresses further the mid-diastolic murmur may be replaced by an early diastolic murmur. This bruit is often interchangeable with a short presystolic bruit, the latter being heard when the heart-rate is rapid, the early diastolic reappearing as the heart-rate slows. The short presystolic murmur is temporary, unaccompanied by a thrill, and distinct from the classical crescendo presystolic murmur of established mitral stenosis.

When the acute infection of the heart subsides the murmurs just described will often be found to retrace their steps. After a few months the early diastolic and short presystolic murmurs settle down into a mid-diastolic bruit, which may persist for several months or years. In some cases the mid-diastolic bruit reverts to a reduplicated second sound, which gradually returns to a normal second sound. In a few cases the systolic murmur also disappears and, as far as one can tell, the heart is then normal. On

The other hand, mitral stenosis may slowly develop from the stage of systolic and diastolic bruits; the first sound at the apex then gradually becomes sharper and louder, while the mid-diastolic murmur sinks up with the first sound until finally the long rumbling presystolic murmur characteristic of mitral stenosis is fully developed. Mitral stenosis does not develop for several years after the original attack of endocarditis. Of the cases analysed, three years was the shortest period in which mitral stenosis developed, but often double that time is required. Fig. 3 shows how the mitral murmurs in 232 children have

FIG. 3.



Illustrating the progress of mitral murmurs towards stenosis (above oblique line) and towards recovery (below line) in 232 children.

changed during a period of from one to two years' observation. The murmurs have remained unchanged in 140, 21 are proceeding to mitral stenosis, while 12 have lost their diastolic murmurs, and in 25 the heart has become normal.

Aortic regurgitation was present in 6 per cent. of 266 children with rheumatic heart disease, a figure which agrees closely with that of other observers. Rheumatic nodules in the subcutaneous tissues, most commonly over the elbows, knuckles, knees, ankles, and occiput, almost invariably indicate the presence of active rheumatic carditis.

The recuperative power of children against disease is a continual source of encouragement to those who work among them, and the very fact that children with early rheumatic disease of the heart are in some cases capable of completely overcoming their heart affection stimulates every effort to help them in their struggle towards recovery.

Tonsillectomy in Rheumatism.

The question of the value of tonsillectomy in rheumatism is a vexed one, and much has recently been written on the subject. Of 600 consecutive cases of rheumatism at the rheumatic clinic at Great Ormond-street tonsillectomy has been performed on no less than 540 (90 per cent.). Of these, 393 were operated upon before their admission to the clinic. Table III. shows the relation between operation for removal of tonsils and the onset of rheumatic pains (174 cases), chorea (143 cases), and rheumatic fever (111 cases). Cases in which visible tonsil remnants remained after the operation have not been included in this Table.

TABLE III.

Rheumatic pains occurred—		
Before and not after tonsillectomy in	.. ..	52 cases.
Before and after ,,	.. ..	53 ,,
After and not before ,,	.. ..	69 ,,
Chorea occurred—		
Before and not after tonsillectomy in	.. ..	73 ,,
Before and after ,,	.. ..	20 ,,
After and not before ,,	.. ..	50 ,,
Rheumatic fever occurred—		
Before and not after tonsillectomy in	.. ..	71 ,,
Before and after ,,	.. ..	4 ,,
After and not before ,,	.. ..	36 ,,

These figures show that approximately one-third of the cases of rheumatic pains, chorea, and rheumatic fever commence these symptoms of rheumatic infection after the tonsils have been removed. In addition, the pains continued after the operation in half of 105 children who had rheumatic pains in the limbs before the removal of their tonsils; and of 93 children who had chorea before removal of their tonsils the chorea relapsed after the operation in 27 per cent.

Unless it can be shown that tonsillectomy has a definite influence in the prevention of cardiac disease, there seems small justification for the operation merely on the ground that the child is a rheumatic subject. Miller[5] has suggested that tonsillectomy is a useful prophylactic measure against rheumatic heart disease, but convincing proof either for or against this view is most difficult to establish. Analysis of 266 children with rheumatic heart disease showed that in 46 cases (17 per cent.) the tonsils had been removed before signs of cardiac disease were discovered. It seems more probable that the value of tonsillectomy in rheumatic children is in proportion to the degree of impairment of the general health attributable to the tonsils. In other words, the tonsils of rheumatic children should not be removed unless there is evidence that they are affecting the general health adversely. Such evidence as a history of repeated sore-throats, chronic enlargement of the tonsillar glands in the neck, and the appearance of the tonsils must all be taken into consideration. The size of the tonsils alone is an unreliable guide, small scarred tonsils being often as injurious to the child's health as hypertrophied tonsils.

I wish to express my sincere thanks to the medical staff of the Hospital for Sick Children, Great Ormond-street, for their permission to make use of figures gathered from the rheumatic clinic.

WILLESDEN CANCER CLINICS.—The report of the first six months' work of the Cancer Clinics, opened by the Willesden Urban District Council, shows that 52 patients attended, most of whom had been attracted by advertisements, posters, and leaflets. In 18 cases the advertisements of various kinds had awakened fear that some condition which had been looked upon as trivial might be cancer, and one patient actually was found to be suffering from cancer in an early stage. Of the others, 17 had "conditions requiring operation or treatment;" 11 had "conditions known to be forerunners of cancer," while six were suffering from conditions the relationships of which to cancer have not yet been established. In 20 cases it was possible to make a definite statement that the patient was not suffering from cancer. The report adds that the clinics have been the means of securing treatment for 12 patients suffering from cancerous or pre-cancerous conditions at a stage of the disease when there is every reason to believe that a cure will be effected or the danger removed.

CLINICAL AND LABORATORY NOTES

PROTEIN MILK IN INFANT FEEDING.

BY NORMAN HILL, M.D., M.R.C.P. LOND.,
PHYSICIAN TO THE METROPOLITAN HOSPITAL AND TO THE BELGRAVE HOSPITAL FOR CHILDREN;
AND
A. W. C. MELLOR, M.B. CAMB.,
LATE HOUSE PHYSICIAN, BELGRAVE HOSPITAL FOR CHILDREN.

PROTEIN milk, or the *Eiweiss-Milch* of Finkelstein, has long been in use both on the Continent and in America as a milk modification suitable for the feeding and treatment of infants suffering from the various forms of diarrhœa and malnutrition. Its value in these conditions does not appear to have been fully appreciated in this country, and although recently the English literature has contained several accounts of feeding with acidified and lactic acid milk, little or nothing has been written concerning protein milk, whilst even the latest text-books contain scant information regarding its application.

Protein milk is prepared, roughly, by rubbing through a fine sieve the dried curd obtained by coagulating a quart of milk with rennet, gradually adding to this curd a pint of buttermilk and making up to the quart with boiled water. Dried varieties are now on the market. The composition of this mixture differs somewhat according to the amount of fat in the milk employed; Holt [1] gives the average as: protein 3·75 per cent., fat 3–3·5 per cent., sugar 1·8 per cent., salts 0·65 per cent.; whilst Langstein and Meyer [2] give: protein 2·8–3 per cent., fat 2–2·5 per cent., sugar 1·2–1·6 per cent., and salts 0·45–0·5 per cent. The calorie value is from 12–14 per ounce.

The advantages of this milk are: (1) the high protein content tends to make the stools less frequent and also alkaline; (2) the small amount of sugar minimises the risk of fermentation; (3) the moderate fat forms soaps which favour the production of formed stools; and (4) the presence of lactic acid makes the curd more easily digested.

As the preparation of fresh protein milk takes a great deal of time and trouble, and as it appears to have no advantage over the dried variety, we have used the latter in all cases, the percentage composition approximating to the higher values in Langstein and Meyer's table. This mixture has a calorie value of about 12 calories to the ounce, and we have used the standard strength in all cases of whatever age. As one of us (N. H.) has now been using this milk for some four years, it seemed to us that a useful purpose might be served in briefly summarising the results.

A SERIES OF CASES FED ON PROTEIN MILK.

Rather less than a hundred cases altogether have been fed on protein milk, a number which we realise is small. In the early trials only the most severe and often apparently hopeless cases of ileocolitis were given it, so that any attempt to prove its efficacy or otherwise by mortality-rates would be fallacious. Latterly we have given this milk early in the disease and kept the infants on it for longer periods, a procedure which we found fully justified by results. In cases of severe ileocolitis our routine is now as follows.

If the infant is not too collapsed and dehydrated, an initial dose of castor oil is given, and the child is fed for the first 12–24 hours on boiled water sweetened with saccharine or 5 per cent. lactose. After this, protein milk is started, at first with no added sugar but sweetened with saccharine gr. 1 to the quart. The sweetening is important, as not a few infants refuse to take protein milk unsweetened, as it has a peculiar, rather sour and unpleasant taste. As soon as the stools have started to improve, which occurs as a rule in one to four days, dextrimaltose is added, at first in very small quantities (half a drachm per feed) and then gradually increasing until eventually 6–10 per cent. has been added. We have been guided in the rate of addition by the state of the stools, it being possible in some cases to add much more rapidly than in others. For the first few days the infant may lose weight, or the weight remain stationary, but often after the first few days the weight increases even before the dextrimaltose has been added. The stools as a rule become alkaline in reaction after three or four days, gradually changing back again to acid as more dextrimaltose is added.

The infants are kept on protein milk for periods ranging from three to six weeks—but never longer—depending on the severity of the case, and then ordinary milk modifications are substituted, starting with two feeds and so returning to feeds suitable in strength and amount to the infant's age.

In cases of malnutrition, with or without undigested stools, we have placed the infant straight away on protein milk with added dextrimaltose, 4–6 per cent., and these cases can usually resume a diet normal for their age after two or three weeks, again depending on the severity of the case.

Two cases of the series in which this milk was used were cases of hypertrophic stenosis of the pylorus with the loose and frequent stools which occasionally follow operation. In both cases the condition rapidly improved and the infants recovered. The youngest case in our series was aged 3 weeks, an infant which was sent to hospital on account of vomiting and loss of weight and suspected duodenal stenosis. This infant took the protein milk well, gained weight, and left the hospital thriving on a simple milk modification.

We have made no fixed rule for the quantity and frequency of feeding, and treat each infant individually, giving as a rule sufficient protein milk to satisfy. Infants fed on this milk sometimes become constipated, but this can usually be overcome by the addition of more dextrimaltose to the feed.

A definite advantage when feeding with protein milk, in cases either of ileocolitis or malnutrition, is that a return to an ordinary feed suited to the infant's age may be made more quickly than when using ordinary milk or dried milk modifications. We have found this fairly consistently and, in addition to benefiting the infant, it enables the institution to employ its accommodation to the best advantage. An occasional difficulty arises in cases of ileocolitis when the protein milk without added dextrimaltose has led to an improvement in the stools, but the stools have relapsed as soon as any dextrimaltose was added and the infant's general condition has become worse, whilst without the added dextrimaltose the feeds were not of sufficiently high calorie value for the infant even to maintain its weight. Some of these infants were tried on other foods without success, whilst in others we attempted to add dextrimaltose, also without success.

COMMENTS.

We consider that protein milk is of very definite help in certain difficult cases of infant feeding, and in many cases in our series it appeared to be the only mixture which the infant would tolerate. Griffith and Mitchell,[3] in discussing protein milk,

[1] Holt: Diseases of Infancy and Childhood. New York. 1926, p. 129.
[2] Abt's Pediatrics. Philadelphia, 1923, vol. ii., p. 749.
[3] Griffith and Mitchell: Diseases of Infants and Children. Philadelphia, 1927, vol. i., p. 158.

state that "although the truth of the original theories which led to the production of casein milk seems repeatedly to have been disproved, the fact remains that the preparation is one of very great value, particularly in many diarrhœal disturbances in infancy." With this we are in complete agreement.

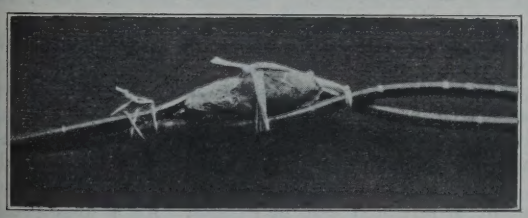
The main points to remember when using protein milk are: (1) that it is a "medicinal food" and that infants should not be kept on it for more than six weeks; (2) that saccharine should be used for sweetening purposes at the onset in cases of ileocolitis; (3) that no gain in weight can be expected until sugar in the form of dextrimaltose is added, and this addition should never be delayed for more than a few days; (4) that although protein milk is a most useful adjunct to infant feeding, it must not be considered as a panacea for every nutritional disturbance occurring in infancy.

CATHETER-EXTRACTION OF A URETERAL STONE PER URETHRAM.

By E. H. R. Altounyan, *M.C.*, M.D. Camb.,
Assistant Surgeon to the Altounyan Hospital, Aleppo, Syria.

Urologists are always urging surgeons to attempt non-cutting methods in the removal of stone from the urinary tract. That manipulation may occasionally be successful is illustrated by the following case.

An Arab male, aged 40, was admitted on Nov. 5th, 1928, with a vesical fistula following a suprapubic cystotomy for stone, performed elsewhere. His general condition was poor, and all urine came through the suprapubic cystotomy, in the scar of which a keloid had developed. On the follow-



Stone removed per urethram. It measured 1·8 × 0·8 cm.

ing day the scar was excised and the bladder drained. On Dec. 4th a stone impacted in the urethra was removed by external urethrotomy. On Jan. 10th, 1929, he underwent a second operation to close the suprapubic fistula, and yet a third on Feb. 5th. The last was successful. On March 4th the urine was still dirty, and a complete X ray examination was repeated, and revealed: (1) a stone in the right ureter, (2) a stone in the pelvis of the left kidney.

In view of the poor general condition of the patient it was decided to attempt to dislodge the ureteral calculus by catheterisation. Two ureteral catheters were passed well up the right ureter, and X rays showed them lying one on each side of the stone. On removing the catheters with considerable effort, something, presumably the stone, was felt to give, though at the moment it seemed probable that the catheters had broken off in the ureter. Next day the procedure was repeated; only after passing the catheters well up towards the kidney it was decided slowly to twist them round and round before pulling them down.

This manœuvre apparently freed the stone from the ureteral wall and at the same time secured a firm grip for the catheters, for on slowly withdrawing them, while keeping up a twisting movement, the calculus was safely delivered at the meatus. The most I had hoped for was a dislodgment into the bladder, but apparently the mouth of the ureter had been drawn down to the orifice of the prostatic urethra, and the transit of the bladder was thus safely accomplished. It seems important to pass the catheters as high as possible towards the kidney. The passage of three or four very fine catheters or sounds might make the result more certain.

It is difficult to explain how it was that on two successive occasions the catheters passed up one on each side of the stone. The whole operation was performed without an anæsthetic, local or general, and patient experienced only moderate pain.

The cases in which manipulative removal of ureteral stones should be attempted must always remain rare, more particularly in view of the fact that the operation of ureterolithotomy is comparatively safe. Personally I would strongly deprecate the use of all special instruments, however ingenious, as their danger increases in direct ratio to their efficiency. The method described of twisting catheters appears worthy of trial.

A CASE OF ECLAMPSIA TREATED WITH SPINAL ANÆSTHESIA.

By R. H. Paramore, F.R.C.S. Eng.,
Gynæcological Surgeon to the Hospital of St. Cross, Rugby.

All cases of eclampsia are of interest, and the one here reported is of especial interest because, in spite of spinal anæsthesia, and even after Cæsarean section and decapsulation of the right kidney, further fits appeared—due apparently in part to the effect of pituitrin.

RECORD OF THE CASE.

The patient was a well-developed primigravida aged 24, seven months pregnant. She was admitted to the Hospital of St. Cross, Rugby, on March 10th, 1930, comatose from eclampsia. She had noticed swelling of the ankles and hands for three or four weeks. On the advice of a nurse who found albumin in the urine, she consulted a doctor (March 5th) but disregarded instructions. The day before admission (Sunday, March 9th) she was up and about, and helped in the cooking. At dinner she ate meat, potatoes, peas, and Yorkshire pudding. She rested in the afternoon, but at supper (9 P.M.) had more peas. At 9.30 P.M. she went to bed, complaining of headache. During the night (3.30 A.M.) she awoke her husband, complaining of feeling unwell. He discovered her in a fit on his return from fetching her mother. Two further fits occurred at intervals of an hour's duration. The doctor was called and gave the patient a quarter grain of morphia and sent her to hospital a distance of ten miles. In the ambulance she had another fit.

She was admitted at 8 A.M., and had a further fit at 9.25 A.M. Chloroform was given. Eight ounces of highly albuminous urine were obtained by catheter, but did not boil solid. A simple enema was without effect, the injection being retained. I saw her soon after; she then looked bloated and was semi-comatose and lying on her back. At 10.45 A.M. spinal anæsthesia (tropacocaine 1·5 c.cm.) was induced under chloroform; she struggled a good deal. She was kept well over in the left lateral position, and the foot of the bed was raised on blocks. At 2 o'clock her condition was rather improved, and there had been no further fit.

The next day (March 11th) she was much better. A good deal of urine had been passed and the bowels had been opened. The blood pressure was 160/95. Water, solution of glucose, lemon water, or water with sodium bicarbonate only were allowed. The day after (March 12th) she was very much better and seemed to be improving fast. Eighteen ounces of urine had been collected, but it still contained a great deal of albumin. The child was alive.

The problem of the renal state—now the central question—was considered; it was thought that the pregnancy must be terminated if the albumin did not diminish rapidly. Hot baths thrice daily were ordered. On March 13th the patient had three hot baths, and on the 14th she had one, but they seemed to do more harm than good. On the 13th she appeared still better; 38 oz. of urine had been collected but it still contained much albumin. The blood pressure was 150/100. But on the 14th she did not look so well—she looked confused. Getting to the bath and back—even with a chair—seemed to have prejudiced her recovery, and that evening the fits recurred. She had one, at 8.40 P.M., for which chloroform was given, and another at 9.14 P.M. Chloroform and spinal anæsthesia were

repeated, and it was decided to empty the uterus and incise the capsule of the right kidney.

At 10.45 P.M. Cæsarean section was done under chloroform, and a small living child (3 lb.) was delivered; pituitrin, 1 c.cm., was given. The abdominal incision was extended upwards and the intestines packed to the left. The peritoneum over the right kidney was incised and its capsule split. By a stab wound in the loin a tube was inserted to drain the kidney area. The peritoneum over the kidney was sewn up, and the abdominal wound closed in the usual manner, without drainage. Omnopon, 1 c.cm., was injected after the operation and, by some extraordinary fatuity, pituitrin, ½ c.cm., was given every four hours. The next day she did not seem to have responded to the treatment as I expected. She did not seem to be passing as much water as she should have been doing. It was not clear to me then that the pituitrin was probably the cause, but it was stopped early in the afternoon of that day. In spite of that, however, the patient had another fit at 4.5 P.M. and a further severe one at 5.40 P.M. For both of these chloroform was given, and at 6 P.M. spinal anæsthesia was induced for the third time. With the patient still under the influence of the chloroform, the rectum was washed out. Yet during the night (2.55 A.M.) a further fit occurred, chloroform and omnopon being given. This was the last. At 7.15 A.M. a simple enema produced a good result; but the omnopon was repeated as a precaution.

On March 17th the patient was much better, the urine increasing, and no further fit had occurred. On the 18th she was so much better as to appear nearly normal; she was sleeping a great deal. On the 19th she appeared to be convalescing rapidly, and only a trace of albumin was found in the urine. On the 21st she was smiling and spoke normally: the œdema had all gone and she did not remember her illness. The wound in the loin was nearly healed and the abdominal wound was normal. The temperature had remained normal. She left the hospital with scarcely any albumin on April 5th. The child did not survive the third day.

DISCUSSION.

As in two former cases,[1] [2] spinal anæsthesia seemed highly efficacious in stopping the fits but in this patient the fits recurred. This is partly to be attributed to the visceral state, which was worse in this case than in the others, as shown by the œdema and the marked albuminuria. Tropacocaine, which acts by reducing the tonicity of the abdominal wall muscles and the blood pressure, cannot be expected to cause more than fleeting changes. Its effect only lasts about an hour and it is thus much more likely to be of service in the fulminating cases of eclampsia—in which a relatively sudden visceral block (to the blood flow) has occurred—than in those in which the pathological process has been progressing more gradually.

In the present case, however, two other factors seem to have come into play. The attempt to deal with the renal state by means of hot baths seems to have precipitated subsequent attacks, whilst the use of pituitrin seems to have determined their persistence. I cannot but think that the hot baths would have been without misadventure—and all for the good—could the patient have been lifted from her bed into the bath, but getting out of bed into the wheeled chair and from the chair into the bath and the return to bed were too much. The visceral block was made worse by the movements and the strain of standing.

It was amazing that the Cæsarean section and incision of the renal capsule should have been followed by further convulsions. The patient had not been fed during her illness in hospital; she had been starved, had been given only water, or water and glucose, or lemon water, and had had no milk. Not only did the fits stop but the urine increased when the pituitrin was stopped, after an interval. In this respect, the reference by Dale[3] to the "long persistent" "antidiuretic" effect of "vasopressin"—one of the active principles of pituitrin—is of interest. If pituitrin has such an effect, the action of spinal anæsthesia, which seems to favour diuresis in eclamptic cases,[4] is not likely to operate. While pituitrin act by constricting the renal arterioles, the spinal anæs thetic operates by reducing the compression of th renal capillaries.

Reflection on these points recalled an earlie experience.

In April, 1928, I performed Cæsarean section on a mult para of 38 because she had a small round pelvis and albu minuria. It was her third pregnancy and she was in labou Albuminuria had complicated her second pregnancy, whic had ended in miscarriage. The operation was performe in the morning under spinal anæsthesia and pituitrin wa injected after the child was extracted. This was quit unnecessary, for the spinal anæsthetic acted well as hæmostatic—as Whitehouse and Featherstone [5] hav recently repeated that it usually does. Throughout th afternoon the patient complained bitterly of "after-pains, and at 7 P.M. had an eclamptic fit.

It almost seems that pituitrin, when injected int women on the verge of eclampsia, induces the fits. I certainly affects the renal vessels; experimentally i has been shown that pituitrin "in a dramatic fashion inhibits the ingravescent polyuria of the heart-lung kidney preparation (Verney [6]). In this respect it i interesting to recall the insistence with which Nichol son [7] long ago emphasised the presence in the bloo of a body acting like digitalis and at times eve constricting renal arterioles to obliteration to explai the state of the kidney and the oliguria or anuri associated with eclampsia. The state of the kidne in pregnant women which predisposes to eclampsia however, is not occasioned by a rising percentage o an increased activity of such a body in the blood but pituitrin injected into an individual whos viscera are already in a state predisposing to a meta bolic convulsion is another matter. Pituitrin i largely used in obstetric practice, and, it seems to me rather indiscriminately. Possibly this may partl explain the occurrence of some or perhaps many case of post-partum eclampsia.

The moral seems to be that pituitrin should not b given as a routine after labour, particularly in case in which eclampsia appears in the least likely—e.g cases with headache, œdema, albuminuria, oliguria Pituitrin after labour is given to prevent or chec bleeding; it should not be forgotten that bleedin at parturition is a normal occurrence and has beneficial effect if not in excess. As a prophylacti for eclampsia, bleeding from the uterus is as effica cious as venesection. Moreover, since the bloo volume increases during pregnancy and must b reduced after the delivery for the normal to b reached, the woman can well afford to lose a certai amount.

I wish to thank Dr. Kremer, the resident medical office who was in charge, for his interest in the case reported an for his care in looking after the patient.

SKIPTON DISTRICT HOSPITAL.—After a long loca discussion the hospital committee have decided to convert large house, named Whinfield, with additions, into a hospita which it is expected will ultimately contain 66 beds. Th total cost, including that of acquisition, will be £11,15 It is proposed to extend the building by the addition of two-storeyed block.

MEDICAL SOCIETIES

EIGHTH INTERNATIONAL CONGRESS OF DERMATOLOGY AND SYPHILIS.

COPENHAGEN, AUGUST 5TH–9TH.

(FROM A SPECIAL CORRESPONDENT.)

Eczema.

As anticipated in your columns, the discussion on the ætiology and pathogenesis of eczema proved to be the most important item on the programme at Copenhagen, and was attended by the whole Congress. It was introduced by Prof. J. Darier (Paris) and Prof. J. Jadassohn (Breslau), who emphasised the main points of their introductory papers, which had been circulated in advance. Prof. Darier took the view that eczema is a clinical entity only in so far as concerns its histology, which is that of a serous exudation in the Malpighian layers (spongiosis), whatever its cause may be. It is, in effect, an "intolerance" of the epidermis to certain stimuli, which vary in quality and degree. It is a vital reaction, and the phenomena implicated do not lend themselves to dogmatic generalisations. Prof. Jadassohn's contribution, which included a somewhat cumbersome classification, was more categorical. He withdrew from the picture the pyodermias, the reactions to fungi, seborrhœic manifestations, and the so-called lichenoid eruptions, and proposed to admit for consideration under the term of eczema only those reactions caused by chemical or physical stimuli, the histological and clinical manifestations of which are well known. They are all of an "allergic" type—that is to say, they occur only in persons of a specific susceptibility, which can be either inborn or acquired—and the causal agent (the antigen) to which they react, and which can nowadays be ascertained by various means, may be either single or multiple. The work of Prof. Bruno Bloch (Zürich), who followed as a "Co-Rapporteur" of the discussion, introduces a new phase into our conceptions of the pathogenesis of the disease, and opens up a fresh avenue of research. As already noted in THE LANCET,[1] he has succeeded in reproducing the clinical and histological picture of eczema in animals. Guinea-pigs have been permanently sensitised by cutaneous applications, intradermal and intracardiac injections of concentrated extract of the *Primula obconica*, contact with which is sometimes a cause of eczema in susceptible human subjects. It is therefore proved that the "antigen" of an eczema—i.e., its cause—can reach the skin either directly or from the blood stream, and when it is known the prophylaxis and therapy are not far to seek. The whole problem depends for its solution on the elucidation and recognition in the future of hitherto unknown causes, and these may be either of external (exogenous) or internal (endogenous) origin. Regarded in the light of these researches eczema is, in the great majority of cases, a specific reaction of the epidermal cells to *exogenous* toxæ, which can be discovered by the investigator in proportion to his care and experience in weighing up the evidence afforded by the history, occupation or trade, environment, and the way of life of the individual patient. The cutaneous tests of certain food antigens appear to be of considerable value in this connexion, and some new work by Gardner and Keston (New York), on Specific Sensitisation in Eczema, read at this Congress, comes at an opportune moment. It is suggested by Gardner and Keston that infantile eczema is the result of a susceptibility to a certain food. If this is not recognised and the reaction persists, the skin becomes more sensitive and may react to more and more antigens as the child grows, so that not only foods, but clothing material, certain pollens, and even bacteria and fungi are rendered causative in the elicitation and continuation of the cutaneous response. This is the type of eczema with which urticaria, asthma, and so on, are frequently associated. It is noteworthy that this line of research demonstrates that eczema occurring for the first time in adult life is rarely due to food, and the majority of these cases are due to direct contact (exogenous) with chemical or physical antigens, or to specific sensitisation to fungi or bacteria. An entirely new aspect of the problem was contributed by Dr. H. W. Barber (London), whose experiments with Dr. G. H. Oriel's urinary proteose have already been published.[2] If future investigations should confirm their findings, which apply to asthma as well as eczema, and possibly to other dermatoses, such as dermatitis herpetiformis of Dühring, yet another avenue of research which may influence and strengthen our therapeutic endeavours will have been opened up.

Tuberculosis of the Skin.

The subject of tuberculosis of the skin and its treatment, introduced in an excellent paper by Dr. H. W. Adamson (London), inspired the production of many of the official communications and provoked much discussion. Prof. A. Reyn (Copenhagen), Finsen's successor in the realm of actinotherapy, demonstrated superb cosmetic effects in properly treated cases of lupus vulgaris. A novel point on which he insisted was the importance of pressing the local applications of the Finsen lamp. A very short interval only should be allowed to elapse between the sessions, and in his experience it is by no means necessary to wait for the subsidence of a reaction from a previous irradiation. Better and more rapid results have followed a combination of the local treatment with the general arc-light baths. After an apparent cure, which followed in the majority of instances in from 8 to 12 months, a prolonged and careful observation for relapses must always be instituted. The more quickly these could be dealt with, said Prof. Reyn, the better the ultimate result. It was, furthermore, of the utmost importance that all practitioners should be prompt in their diagnosis and refer the patient to the proper quarter before the disease had caused disfigurement. An early lupus patch could easily be excised, and this was sometimes the most satisfactory treatment, and certainly had the great advantage of saving time and eradicating the focus. Other speakers confirmed the desirability of excision in early cases. The results of the salt-free and other dietetic measures had not been at all encouraging in Copenhagen, although Prof. O. Ganz (Heidelberg) reported considerable improvement in the exudative type of case. The gold treatment was, for the most part, also condemned, and the general opinion of X rays was that if they were used at all they should

[1] THE LANCET, August 2nd, 1930, p. 251.

[2] Ibid., p. 231.

be applied with extreme caution and only by those who had seen the serious results of overdosage, among which epithelioma had certainly to be feared.

An important paper was contributed by Bruusgaard (Oslo), who succeeded in demonstrating that quite a large proportion of lupus vulgaris in children had been contracted from cases of open pulmonary tuberculosis in one or other of the parents, the relatives, or the nurse who came in daily contact with the children. Such children always showed some pulmonary or hilus gland infection on careful radioscopy, and he was convinced that it was only very rarely that the disease was contracted by way of the skin or alimentary canal. Whenever children were exposed to the possibility of infection they should be removed to a healthy environment, or such steps taken as would render the chances of such a disaster remote. The observation by Prof. R. Volk (Vienna), that although in some cases the bovine bacillus might be the causal factor in production the greater number of lupus cases were infected with the human variety, was in agreement with the views of most authorities. According to him the clinical picture produced is thus not so much the result of a special virulence as the reaction of the patient's own tissues—i.e., his individual resistance. This picture is neither constant nor fixed, and can very easily be altered by the patient's unaided reactions—or by the injection of substances like tuberculin or sanocrysin—for better or worse. It follows, and this was emphasised by other speakers, that injections of all kinds in lupus vulgaris should never be given without a most careful and exhaustive preliminary examination of all the systems in which tuberculous foci might be lying dormant.

Erythema Multiforme.

Of the shorter communications that by Prof. E. Ramel (Lausanne) was by far the most interesting and important. He has carried his investigations on the ætiology of erythema multiforme a stage further, and it seems probable that the syndrome is yet another manifestation of tuberculosis in the human subject.

The preliminary results of "échelon" or "passage" inoculations of the blood of patients in the acute stages into guinea-pigs was reported by Ramel and discussed at a Congress of French dermatologists in Paris last year, and have also been published in this journal.[3] His claims were substantiated by another investigator, who has repeated his experiments, and who announced his confirmatory results at this Congress. Ramel has now found the tubercle bacillus by guinea-pig inoculation in the blood of 21 patients submitted to the test, and in one of these he has actually succeeded in demonstrating the organism (in films stained by the Ziehl-Nielsen method) *from the lesions themselves.* If this latter procedure can be successfully repeated by other workers the tuberculous origin of erythema multiforme, with its occasional joint and serous cavity complications, will have to be accepted as proven. The rôle of the streptococcus, which has always been regarded as causal, in this country at any rate, will then be relegated to the position of a determining or sensitising factor like sunlight, trauma, or the action of certain drugs in the antipyrin group.

Psoriasis.

Another interesting communication of a more speculative kind was that submitted by the Dutch dermatologist, Dr. v. Kerckhoff (Leiden), on the ætiology of psoriasis. In a series of histological sections stained by solutions of nitrate of silver he demonstrated the absence, or relative diminution, of melanin and pigment cells in the basal layer of the epidermis. This deficiency was noted not only in the psoriasis patches themselves, but also in the apparently normal skin of such patients. Exposure of the body to sunlight and artificial light was followed by an irregular and patchy pigmentation which demonstrated the loss of function to the unaided eye. Kerckhoff deduces from these and other complex facts that psoriasis is a "light deficiency disease"—a disease in which an inefficient oxidation is an underlying association. Such a theory is further supported by the fact that all the local applications used in treatment are more or less powerful oxidising agents, such as pyrogallol, chrysarobin, and its synthetic standardised, and much more cleanly and powerful substitute, cignolin, which is effective in a concentration as low as 1 per cent. in the average case of the disease.

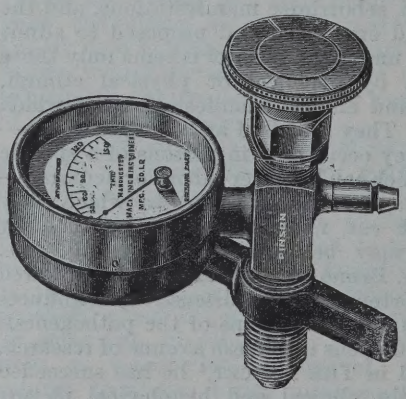
NEW INVENTIONS

AN IMPROVED FINE ADJUSTMENT OXYGEN VALVE.

I HAVE made some improvements in my fine adjustment oxygen valve, particularly with regard to the pressure gauge which indicates the quantity of gas left in the cylinder. The gauge shown in the accompanying illustration has an improved movement which obviates backlash of the pointer, and is also cheaper in production. It is built as an integral part of the valve, which does away with the comparatively expensive union between gauge and valve—a union too, which was rather liable to develop leaks if accidentally knocked or tampered with.



The instrument is manufactured by the Manchester Machine and Instrument Manufacturing Co., Ltd., 2, Booth-street, Manchester.

K. B. PINSON, M.B., Ch.B. Birm.

TUNBRIDGE WELLS JOINT HOSPITAL.—The scheme for a joint hospital on the Culverden site is likely now to come to fruition. An amalgamation between the General and Counties and the Eye and Ear Hospital is considered likely to help both institutions. The original scheme was declared by an advisory committee to be a sound but uneconomic one. The cost was to be £1200 per bed, but the committee found that a modern hospital could be built and equipped for £1000 per bed. Revised plans and estimates have now been presented and for 180 beds—70 more than in the two hospitals at present—the cost will be £180,000. This figure has been approved by the governors who are assured that the reduced cost will in no way sacrifice the permanent efficiency of the new hospital. An appeal to supplement the money already raised for the first scheme is to be launched as soon as the holiday season is over.

REVIEWS AND NOTICES OF BOOKS

The Autonomic Nervous System.

By ALBERT KUNTZ, Ph.D., M.D., Professor of Anatomy in St. Louis University School of Medicine, Missouri. London: Baillière, Tindall and Cox. 1930. Pp. 569. 31*s.* 6*d.*

IN view of the ceaseless output of articles and books concerned with one or other of the numerous aspects of sympathetic activity, physiological and clinical, it is well that the fundamentals of what is coming to be a highly important subdivision of medical science should be set down in a historical framework and at the same time rendered conspicuously clear. The foundation of advance must be anatomical; to postulate functions is meaningless if evidence of anatomical mechanisms whereby they can be carried out is awanting. The student of the subject must go back to the beginning, and there is the more reason for doing so in that the morphology and microscopic anatomy of the involuntary nervous system, so called, have not yet been fully elucidated. He owes a debt of gratitude to Prof. Albert Kuntz for this compact study of essentials, which is distinguished alike by its scholarliness and its reserve.

Adopting Langley's original nomenclature, Prof. Kuntz divides the autonomic system into its components, sympathetic and parasympathetic, and deals seriatim with anatomy (microscopical and general), physiology, and development; thereafter a series of chapters are devoted to the innervation of particular organs (heart, blood-vessels, respiratory system, glands, and so forth, including all the main structures of the body); other chapters handle controversial subjects such as vagotonus and sympathicotonus, the autonomic innervation of striped muscle, and the relation of visceral sensitivity to referred pain. Finally, a sketch is given of diseased states of the system, and of its surgery. This brief conspectus gives the reader some idea of the width of range of the topics to which the author turns his attention, and at the same time must suggest to the instructed mind many points on which information is likely to be wanted. One disadvantage of the work is that the author perforce has to set down more or less dogmatically conclusions which subsequent knowledge may modify, or to draw them from insufficient data. These difficulties Prof. Kuntz has, in our view, met with remarkable skill, for he never fails to indicate in what respects knowledge is incomplete, or to outline conflicts of opinion and evidence and allow the reader to come to heuristic decisions for himself. As a single instance, he declares "it cannot be denied that muscle tonus is influenced directly or indirectly through the sympathetic nerves," yet does not omit to state how inconclusive much of the evidence is, and finally (and, as it seems, correctly) refuses the view assigning a definite (plastic) component of muscle tone to the direct effect of autonomic nerves on muscle-fibres. This fairly represents, we believe, the exact stage to which present information takes us (see THE LANCET, July 19th, p. 127). Again, judgment is suspended in respect of operations on the sympathetic system for relief of visceral pain, yet here also the far-reaching possibilities of the procedures are not ignored.

An extensive bibliography adds to the value of a work worthy of unreserved praise.

Mycoses of the Spleen.

By GEORGE ALEXANDER GIBSON, M.D., F.R.C.P., Physician to the Radcliffe Infirmary and Reader in Morbid Anatomy in the University of Oxford. London: Kegan Paul, Trench, Trübner and Co., Ltd. 1930. Pp. 169. 12*s.* 6*d.*

THIS book is written to prove, in the words of the author, that "we cannot escape the main indication that acholuric jaundice, splenic anæmia, and Banti's disease are infective in origin." Dr. Gibson produces much evidence in support of his thesis that the infecting organism is a mould, but it is not altogether convincing. It rests mainly upon the demonstration, by various staining methods, of structures within spleens removed during life or after death from patients who suffered from the conditions named, these structures being held to be mycelial threads. In many of Dr. Gibson's illustrations the structures do indeed appear very much like fungi; in others the resemblance is not particularly close. If we bear in mind the numerous pitfalls in the interpretation of histological appearances of this kind the evidence supplied seems far from conclusive. The bodies found in the lungs of asbestos workers look extraordinarily like minute crustacea; no one has yet been bold enough to claim that they are crustacea. In the absence of normal controls, the isolation of moulds from 7 out of 37 enlarged spleens is not impressive, and the results of animal experiments give little support to the theory. The author passes lightly over the difficulty of reconciling the hereditary disposition and the microcytosis of acholuric jaundice with the infective hypothesis. It must be remembered, however, that Dr. Gibson speaks with authority; he was one of the first to attribute a mycotic origin to certain types of splenomegaly and has devoted many years to the study of these conditions. Moreover his views have found much support, notably in France, and they are not lightly to be dismissed. The case remains unproven but the avenue requires further careful and unbiased exploration. Chapter XI. containing details of the author's own cases makes heavy reading; the subject matter here included might with advantage have been arranged in tabular form. The book includes a valuable compendium of recent French literature on splenomegaly.

On Faith and Science in Surgery.

By Sir JOHN BLAND-SUTTON, Bart. London: William Heinemann. 1930. Pp. 109. 7*s.* 6*d.*

UNDER this title Sir John Bland-Sutton has republished ten addresses delivered, between the years 1925 and 1930 inclusive, on various occasions when medical or public audiences were gathered together in the metropolis, in large provincial towns in this country, and in the United States and Canada. The various essays, in the course of publication as a collation, have been edited for the purpose and freely embellished with excellent wood engravings. All of them are fairly covered by the title, and provide striking examples of their author's manifold learning and great skill in translating that learning into simple precepts and readable information. Many discoveries and observations made by naturalists have the closest relation to medicine, and in those directions animal psychology and animal inventiveness parody the

activities of mankind, and suggest both texts to the philosopher and therapeutic measures to the doctor. Sir John's olla podrida is a reply to the double suggestiveness. He deals with foods and drugs, and with the sensations of animals that have been swallowed alive; with methods of ligature and with the mentality of conjoined twins; with "attic salt for gall-stones," and the aquatic origin of man; with "the glandular pantheon" and the conquest of sepsis—to pick out a few intriguing titles which will induce readers to consult the little volume. That indeed is the idea of this brief notice, for those who read will be repaid.

Ultra-violet Radiations and their Uses.

By ROBERT AITKEN, M.D., F.R.C.P.E., Lecturer on Diseases of the Skin, Edinburgh University; Assistant Physician in charge, Dermatological Light Department, Royal Infirmary, Edinburgh. London: Oliver and Boyd. 1930. Pp. 208. 10*s.* 6*d.*

Dr. Aitken, who has had 17 years' experience with ultra-violet light as a therapeutic agent, is well qualified to speak authoritatively on the uses and limitations of light treatment. He considers that ultra-violet radiation is valuable in the treatment of many dermatological conditions, such as alopecia, furunculosis, psoriasis, burns, and so forth, and that it is of the greatest use in the treatment of lupus. Dr. Aitken is also a firm believer in the general tonic value of ultra-violet light treatment and in its sedative action on restless patients. He discusses critically the sections of the report of the Medical Research Council (1927–28) which deal with this subject, in view of his own clinical experience and of the report of the Scottish Board of Health for 1926.

The historical and scientific sections of the book add little to our knowledge of the facts on which actinotherapy is based, and it may perhaps be questioned whether a restatement of these facts in an elementary form is justified, in view of the number of elementary text-books on actinotherapy already in existence. The statement that eosin painted on a part renders it more sensitive to light will be queried by other experimenters, since actual injection of this dye into the tissues is usually considered necessary to obtain a sensitising action.

Physiological Principles in Treatment.

Sixth edition. By W. LANGDON BROWN, M.D., F.R.C.P., Physician to St. Bartholomew's Hospital. With the collaboration of R. HILTON, M.B., M.R.C.P. London: Baillière, Tindall and Cox. 1930. Pp. 464. 10*s.* 6*d.*

THE importance of physiology in medicine and particularly in the understanding of essential principles of treatment requires to-day no emphasis. There is still, however, a tendency towards haphazard therapeutics and a lack of appreciation of the fundamental defects which treatment aims at correcting. A realisation of disorders of function must depend upon an accurate knowledge of human physiology. This volume contains a mass of sound advice and wise guidance. The book is comprehensive in scope and is written with such a full appreciation of practical issues as to be a valuable handbook of treatment. In this edition the sections on diabetes, the parathyroids, vitamins, gastric secretion, and the treatment of Graves's disease have been revised, and new work on the ovarian hormones and liver treatment in pernicious anæmia has been incorporated. A large portion of the book is taken up with a consideration of alimentary and metabolic disorders, and we miss any full consideration of anæmia and the uses of blood transfusion, or on the value of such measures as phrenicotomy and artificial pneumothorax. However, the book makes no claim to be a complete review of modern principles of treatment, and the authors are to be congratulated upon the discretion they have shown in the selection of the subject matter. Their book should be in the hands of all who would guide their treatment along rational lines.

Science in Soviet Russia.

By J. G. CROWTHER. London: Williams and Norgate, Ltd. 1930. Pp. 128. 7*s.* 6*d.*

IN a series of interesting chapters Mr. J. G. Crowther who has already shown himself a capable exponent of scientific subjects in simple language, communicates the result of a short visit to Russia where his time was spent in the scientific institutions of Leningrad and Moscow. He acknowledges inability to speak or read Russian, so that the information which he gives, as well as his deductions, are based on communications the accuracy of which he could only check by personal observation. The outcome is a very readable account of what "science" in Russia to-day really implies, with certain well-balanced estimates of what the future may bring forth.

The limitations of the information are obvious. Mr. Crowther writes frankly from the communistic point of view, and admits that in the organisation of scientific work in the Soviet Union definite stress is laid upon the political views of the workers—in other words, those who falter in their allegiance to Soviet dispensation may at any moment find themselves without occupation. What will come of the "integration of science, the State, and the industry of the country"—the phenomenon which we are asked to envisage—may or may not be that world-power which Mr. Crowther regards as possible in 20 years' time, for the accuracy of the forecast must depend upon the conditions under which this union of public interests and individual endeavour takes place. To take as an example of what is meant by "integration" we find a Government department under which certain scientists receive certain salaries to do whole-time work, the result of which will be expressed in terms of pure science or of applied science, as the work can be utilised in industrial directions. It would seem that the outcome of the particular activities must depend for its value primarily on the capacity of the men chosen to do the work, but indirectly upon the security of tenure enjoyed by the workers. Soviet Russia recognises no difference between "pure" science and "applied" science, recognising that all research work demands the same ideals of honesty, accuracy, and pertinacity; but will these ideals be reproduced materially if, to quote the author, "a purging of intellectual institutions takes place" when "'wobblies' have been given the sack."

Every page in this enthusiastic little book suggests that the vast and multiple efforts towards scientific discovery made under the creative urge of modern Russia must bear fruit in directions which imply vast national wealth and the power that will spring therefrom. But every page also suggests that the world is watching a gigantic experiment, and this at a distance from accurate knowledge of conditions which renders thoughtful surmise little better than guessing.

THE LANCET.

LONDON: SATURDAY, AUGUST 23, 1930.

THE HEALTH OF THE CASUAL POOR.

FEW small sections of the community have been o much the subject of investigation and legislation s those individuals who tramp about the country nd seek shelter at night in casual wards. From udor times until the present there has been a ong series of enactments and official inquiries oncerning vagrancy and the reactions of the agrant upon society at large. The last of these fficial investigations was entrusted by the present linister of Health to a Departmental Committee, hose terms of reference were "to inquire into the dministration of the laws relating to the relief f the casual poor, and to make recommendations ith special regard to the assistance of persons eeking work, and to persons suffering from hysical or mental disability"; this Committee, hich began its work at the end of last year, as just issued a report, of which a brief summary ppears on p. 415.

It is worthy of special note that in this latest nquiry the attention of the investigators is specially rawn towards the disabilities of the destitute ayfarer. Hitherto, the health of the tramp, hen it has come up for consideration, has been egarded more from the point of view of the ublic than from his own, and from time to time e has been suspected as a disseminator of disease nd generally as a "nuisance injurious to health." hus, in 1893, and again in 1904, the late Dr. H. E. RMSTRONG, at that time M.O.H. for Newcastle-on-yne, published reports in which he showed the elation of small-pox to vagrancy. Again, at the eginning of 1928 a number of cases of small-pox ropped up among persons in casual wards and ccounted in some measure for the spread of ne disease from district to district. On this ccount and by means of Circular No. 859, boards f guardians were requested by the Ministry of Iealth to instruct their medical officers to examine ll casuals daily. This routine examination was ontinued for nine months during which period ver 100 cases of small-pox among casuals were rought to light. At the same time a general urvey of the physical conditions among casuals as made by the various medical officers, and out f 120 reports received from these officers 80 per ent. testified favourably to the physical well-eing of the casuals examined. Apart from this vidence the Committee at the outset of its nquiry had no sort of statistical data upon which o base further investigations, or form conclusions bout the physical disabilities of casuals; such evidence, however, as was given by the various witnesses during the course of the inquiry generally corroborated that of the medical officers referred to above. The estimates of the proportion of casuals suffering from mental disabilities, as given by witnesses, showed a wide variation; to secure some statistical information on this matter, therefore, the Committee wisely availed itself of the offer by the Board of Control to allow Dr. E. O. LEWIS of that department to undertake a special investigation on their behalf. It will be recalled that in his report, which was published by the Mental Deficiency Committee of 1929, Dr. LEWIS arrived at the somewhat startling conclusion that the mean incidence of mental defect in England and Wales was 7·34 of the population at large. The results obtained on this occasion by Dr. LEWIS from the examination of nearly 600 casuals in various representative institutions throughout the country are equally arresting, and they appear in Appendix III. of the report under consideration. Briefly, it appears that, of 592 casuals examined (including 50 women), 159 showed signs of abnormal mental condition; thus, 15·7 per cent. were classed as feeble-minded, 5·4 per cent. as insane, and 5·7 per cent. as psychoneurotic. All the mental defectives were of the feeble-minded type and no idiots or imbeciles were observed; the majority of those classed as insane were suffering from senile dementia, and several of those in the psychoneurotic group resembled cases of "shell-shock." Stammering, often severe, was frequently observed among members of this last group.

Arguing both from the accepted teaching that the incidence of mental deficiency in any group of persons is a reliable index to the amount of subnormal mentality in the group as a whole, and from his actual observations in the present instance, Dr. LEWIS concludes that the majority of casuals must be considered as persons of subnormal intelligence. If this be so it would help to explain in some measure perhaps the social inefficiency which characterises so many of the vagrant class. Several other interesting and significant observations were made about the physical condition of casuals examined during this special inquiry. Thus, the group of casuals as a whole was found to be surprisingly free from respiratory disease, and only one definite case of advanced phthisis was found; chronic alcoholism was diagnosed in no less than 75 cases; skin diseases were very rare, and as an indication of general bodily cleanliness it is recorded that, despite diligent search, only one case of scabies was found, and only very few casuals showed marks of flea-bites. From a consideration of the figures for height and weight and from other circumstances, Dr. LEWIS concludes that the nutritional condition of the casuals examined was not materially inferior to that of the general population. The total number of cases which Dr. LEWIS was able to examine in the time available is small, but his results as regards the mental conditions of casuals certainly justify the Departmental Committee in recommending, as they have, that there should be periodical inspection of casuals both by the medical officers of the

institutions to which they resort and by specialist medical officers of mental deficiency authorities. The thought that, as Dr. LEWIS computes, some 1800 mental defectives—apart from others of unstable mind—are roaming the country as destitute wayfarers is disturbing and warrants the hope that arrangements for medical examination such as the Committee recommends may be instituted without delay. On the other hand, Dr. LEWIS'S observations on the bodily cleanliness, skin state, and nutritional condition of casuals are more reassuring and would seem to imply that in many casual wards, at any rate, the measures designed and carried out for the personal hygiene and bodily comfort of the casual poor have not fallen far short of the standards which the Committee would like to see generally adopted.

The report of the Committee appears opportunely, at a time when the administrative care of destitute persons has passed to new and larger authorities, armed with greater powers than had their predecessors for carrying out such medical recommendations of the Committee as may be subsequently endorsed by the Minister of Health.

MEDICAL TREATMENT OF CANCER.

DELAY in the diagnosis of malignant growths or their occurrence in such inaccessible situations that no radical cure may reasonably be expected from surgery, X rays or radium, involves the patient in a situation generally so hopeless that no systematic plan of treatment can be undertaken apart from the relief of physical suffering by sedatives. The prevailing atmosphere of gloom appears to induce in physicians a paralysis of effort which is both unreasonable and discreditable, for although it may be true that little can yet be done in the way of specific treatment for advanced malignant disease a great deal can be done for the victims of it. The paper by Dr. A. T. TODD in our present issue is a notable contribution to this neglected aspect of practice, and it is rendered particularly interesting by reason of his conviction of the value of lead selenide in the treatment of cancer. The introduction of the treatment of malignant disease by intravenous injections of colloidal lead by Prof. BLAIR BELL and his colleagues at Liverpool was first announced in 1922; but in view of the toxicity of the remedy it seemed wise to the Liverpool workers to delay publication of the methods by which their remedy was prepared and subsequently to restrict its general supply for a time. The thorough investigation of the potentialities of lead did not, therefore, take place for some time, and even then the disastrous results of the indiscreet use of the method obscured the important clinical fact that occasionally very remarkable benefit followed its employment. It is now clear from the work of TODD in Bristol and of THOMSON and SANDERS in Birmingham that occasionally in the treatment of advanced malignant disease various compounds of lead in suitable doses may produce definite improvement without subjecting the patient to the risk of the rapid deterioration of his general physical condition that sometimes followed the use of very large doses. In Birmingham and in Bristol the tentative conclusion has been reached that lead acts indirectly by stimulating some general resistance to malignant disease and, on this assumption, as Dr. TODD emphasises in his paper, it is desirable to employ any additional measures that could conceivably assist the process.

The evidence for the existence of such general resistance to invasion by malignant growth is drawn chiefly from clinical observation. Any careful observer must be impressed with the unequal progress of some fatal cases of cancer; for long periods all activity of the growth may appear to be suspended, and the patient's condition remains stationary until in a comparatively short time the disease makes serious headway. Alternating phases of this kind are by no means uncommon and it is difficult to explain them on any other basis than that of a waxing and waning of general resistance. There is further the fact, with which radiologists are familiar, that sometimes exposure of one superficial metastasis of growth to X rays is followed within a few days by definite regression of other metastases which have been shielded from the direct effect of the rays; this suggests the possibility that absorption of the necrotic products of radiation has induced a systemic reaction to the disease. Finally, there are the few but indubitable instances of spontaneous recovery from malignant disease.

The nature of the factors underlying these clinical phenomena remains obscure, but that is no reason why physicians should not attempt to influence them favourably; such work has a value beyond the relief obtained in individual cases, for in a discouraging field it serves to keep alive that spirit of independent clinical inquiry which is the essence of medicine. Dr. TODD makes few claims. The group of workers under his guidance have not expected to cure the patients accepted for treatment, since these were advanced inoperable cases chosen only on certification that nothing could be done for them, though they were not actually moribund. The aim was to demonstrate the utility or otherwise of lead selenide in producing relief of pain, euphoria of the patient, and regression of the cancer. Only after a technique had been evolved was it hoped to apply the method to earlier cases, with less widespread growth, and therefore some hope of survival. Dr. TODD for these reasons offers no statistics, but he proceeds to describe the preparation used, the dosage in different types of cancer, the remedial effects observed in experimental animals and in man, and, finally, outlines the case for devising a technique for concurrent radiation and lead selenide therapy. Additional measures—the administration of calcium chloride, the fat-soluble vitamins in large doses, thyroid extract in small doses and liver extract—are also used in his wards and since it is not certain how much the interaction of these various medicaments conduces to the results obtained, he advises that none of

them should be omitted. He commends his methods to surgeons for trial (1) after recovery from irradiation, (2) after the removal of as much of the growth as possible in inoperable cases, (3) after operations regarded as complete, in case complete removal has not been achieved.

LOCAL REST IN PULMONARY TUBERCULOSIS.

THE basis of the modern treatment of all forms of tuberculosis is rest. The pharmacopœia has provided a few palliatives for some of the more distressing symptoms of the disease but has failed to supply any drug having the slightest influence on the course of the malady. The laboratory has supplied a series of vaccines, some dangerous, some at least innocuous. If collapse therapy is able to boast of occasional successes where all other forms of treatment can only record failures, it is because by its means the tuberculous lung is set at rest. Were diagnosis always made at the onset when the disease is usually limited to a small area of one lung and were the pleura less liable to the formation of adhesions, the treatment of pulmonary tuberculosis would be a simple matter. Unhappily a completely successful artificial pneumothorax is the exception rather than the rule. In some cases adhesions are already present as the result of old pleurisy before the lung parenchyma is attacked, in others they are due to localised pleurisy over recent disease. In either case they prevent the complete collapse of the lung. Sometimes partial collapse may suffice to abolish symptoms and to banish tubercle bacilli from the sputum. More commonly, however, the healthy parts of the lung alone retract, while cavities remain gaping owing to the bands which tether the diseased areas to the parietes, tubercle bacilli are still expectorated, and sooner or later there is inhalation spread in the opposite lung.

If artificial pneumothorax fails, surgical methods offer the only means of attaining pulmonary collapse. The surgical methods include: (1) Internal pneumolysis: the severance of adhesions by cautery or diathermy cutting current under endoscopic control. (2) External pneumolysis: the separation of the parietal pleura from the chest wall over the diseased area and packing of the space thus formed by paraffin, fat, or muscle. (3) Phrenic avulsion: the removal of the phrenic nerve by traction through a small cervical incision. (4) Thoracoplasty: the removal of segments of some or all of the fixed ribs from one side of the chest so as to allow the chest wall to sink in. The results of the cauterisation of adhesions in suitable cases are excellent, as witness recent papers[1] in our own columns by G. MAURER and F. G. CHANDLER. But all cases are not suitable for this treatment; the thoracoscope can only be used when there is a pleural space and general adhesions may prevent its employment. External pneumolysis seldom gives satisfactory results. The minor operation of phrenic avulsion and the major operation of thoracoplasty are those most commonly employed. The type of case most suitable for thoracoplasty is the fibrocaseous, unilateral and comparatively inactive, where an adherent pleura prevents or nullifies the benefit of artificial pneumothorax. The general resistance must be good. The patient's mentality must be hopeful and the social circumstances not unfavourable. The operation is a severe one and the general consensus of opinion is that it should be done in at least two stages. The disadvantages of two or more operations instead of one—and the disadvantage from the patient's point of view is a grave one—are held to be outbalanced by the lessening of shock and the avoidance of too sudden a strain on the contralateral lung. The results of thoracoplasty are difficult to assess. If cases are rigorously selected, if operation is limited to the more chronic types of unilateral disease, the results are good. But it is not easy to say what the later history of many of the cases would have been without operation. Many patients suffering from chronic fibroid phthisis remain for indefinite periods in fair health and activity without any special treatment. Artificial pneumothorax achieves its most dramatic successes in the acute febrile types of disease; thoracoplasty can only be offered to patients who are afebrile and in no immediate danger. Nevertheless the results claimed for thoracoplasty are impressive. Thus BÉRARD and DUMAREST,[2] in a series of 98 cases operated on before January, 1929, obtained amelioration of symptoms in 7·1 per cent., good results in 18·3 per cent., and very good results in 22·3 per cent. Since 1925 no patient has died in their clinic as the result of the operation.

Though phrenicotomy is a far less effective means of securing lung collapse it is a much less drastic procedure and it is more widely applicable. Fever does not contra-indicate its employment. The patient's resistance need not be good, for the operation entails as a rule no shock. Its value is not referable to the pulmonary base alone, for, as BÉRARD points out, a partial immobilisation of the whole organ is obtained. Phrenic avulsion should always be practised as a preliminary to thoracoplasty, it may render an apicolysis or partial thoracoplasty more efficient, and may even bring some relief to a contralateral lung which is attacked by disease after its fellow has been put at rest by surgical interference.

HOSPITAL SATURDAY FUND.—The fifty-seventh annual appeal will be made by this Fund on Saturday, Sept. 27th, which will be its flag day. Last year £83,000 was distributed among hospitals and allied institutions by the Fund.

CHARING CROSS HOSPITAL.—Last year 4160 in-patients were admitted and stayed on an average 21 days, costing £11 17*s.* 6*d.* each. The 28,146 new out-patients included 18,881 casualties; their average cost was 7*s.* 5*d.* Improvements have been carried out at a cost of £100,000, all of which has been obtained, and on an expenditure of £57,261 there was a credit balance of £1688.

ANNOTATIONS

THE PARENTAL STATE AND IMPERSONAL MEDICINE.

ADDRESSING the Ottawa Canadian Club on the theme of medicine and statesmanship last week Lord Dawson of Penn sounded a note of warning to which both the statesman and the doctor of to-day may well listen. He pointed out that the doctor of the old school thought of the sick person as a human being who, for the time being, was separated by inexplicable illness from the stream of life, and thus the doctor himself tended to become cloistered—separate in thought from the body politic. In modern times the wider appreciation of the value of preventive medicine, in response to its wider applications, had brought with it a more intimate contact on the part of the doctor with the daily life of the people, and not only of those people who are laid aside by sickness, but also of those who are enjoying health and strength. Alongside this development in medicine, Lord Dawson pointed out, there had been a similar movement in statecraft, for after the various struggles of the people for liberty and self-government the State had acquired a parental function expressed in the help provided for those who were helpless through their infancy, their ignorance, their want, or their unemployment.

The State to-day regulates wages and hours of labour, as well as cares for its weaker members, and is prompted to all this parental action by a social conscience, and in tracing out the lines of development of this function Lord Dawson forecast certain results. There was, he thought, no attribute of the human being more notable than his individuality. "Parade a thousand men and each would be found to be distinct—even to his finger-prints." By long exercise of his intuitive mind the doctor has to take cognisance of this personal factor; is not personality of equal importance to the statesman? Here the speaker pointed to the danger that might follow on the State being compelled to consider the individual "so standardised as to be hypothetical rather than real." This is a shrewd warning to many publicists to-day, who in their honest desire to see that an equality of opportunities should offer itself to the largest possible number of citizens are apt to forget that the best work will always be done when the incentive of individual stimulus is present. Attempts to standardise the human being in medicine have never been a success. Even the laboratory tests of normal function have not been conspicuously successful—the individual too often eludes the common test. Prof. Julian Huxley, in one of his earlier writings, remarked that "the essential quality of an individual is not life but individuality," and it is not a tautological platitude but a truth of physiological importance. In the sphere of practical medicine there is surely a grave danger lest the assumption should be made among those who are in social authority that all those reactions of the human personality which we call illness can be docketed on an official form and dealt with by an administrative office. No one takes this view in respect of acute emergency, but too many persons are prepared to think along these lines in branches of our science that are equally, if not more generally, important. No scientific man, and, of course, no doctor, is in danger of assuming that a series of specialist officers, in whatever profession they may be expert, could watch over and protect human destinies, but Lord Dawson's view that the State should be ready to take specialist advice on the advisability of social departures is sound, now that the business of Imperial Parliamen is so diffuse and necessarily so influenced by party considerations.

THE BLOOD BILIRUBIN IN "APOPLEXY."

THE diagnosis between cerebral thrombosis and cerebral hæmorrhage is not always such a simple matter as the text-books would have us believe Thrombosis sometimes occurs with startling sudden ness and the onset of symptoms following hæmorrhage may be quite gradual. Since the treatment of the two conditions is in many respects opposite and prognosis also differs fundamentally the distinction is one of extreme importance. Hence any assistance in the differentiation of the conditions that would supplement the results of clinical examination would be welcomed. Dr. G. Cheney [1] has recorded observations on the amount of bilirubin in the blood after "apoplexy" in a number of patients suffering from cerebro-vascular accidents. After extravasation of blood into a closed space the blood-pigment is gradually absorbed from the affected area and taken up in the blood stream. There is thus an increase for a time in the amount of blood-pigment circulating in the blood. Clearly after a cerebral thrombosis with subsequent softening of brain tissue no such absorption of blood-pigment should occur, at least to any marked degree. Dr. Cheney has followed up the original study of J. Wilder [2] in Vienna upon this assumption. In Wilder's cases the serum bilirubin was found to be definitely increased in the majority of patients suffering from cerebral hæmorrhage and he concluded that one could determine in this way with great probability whether an "apoplexy" was due to thrombosis or hæmorrhage. Dr. Cheney reports his own series of 50 cases in which the blood bilirubin was estimated from one day to three months after the attack; in only five of them, however, was post-mortem confirmation of the diagnosis possible. The icterus index, which is a simple colorimetric estimation of the quality of bilirubin in the serum, and the van den Bergh reaction were determined in all the cases. Of the 32 patients described, 17 showed blood bilirubin above the normal; only three of them came to autopsy, and of these one showed a large subdural hæmorrhage due to trauma and the remaining two multiple small brain hæmorrhages due to uræmia. Dr. Cheney concluded that nine of the others showed some evidence of hæmorrhage; but this observation has little value in view of the fact that of the 15 who showed normal or borderline bilirubin values, at least five were probably hæmorrhage. The van den Bergh reaction was also carried out in all these patients since a direct positive result, indicating biliary tract disorder, obviously obscures any changes due to hæmatogenous causes. Cheney's results, therefore, do not confirm the hope that the determination of the serum bilirubin is a method capable of indicating consistently the presence of cerebral hæmorrhage as against a cerebral thrombosis; on the other hand a definite increase in the serum bilirubin (without a positive direct van den Bergh reaction) after cerebro-vascular accident indicates the probability of a hæmorrhage. It is an interesting circumstance

[1] Cheney, G.: Amer. Jour. Med. Sci., July, 1930, p. 24.
[2] Wilder, J.: Wien. Klin. Woch., 1927, xl., 1158.

that in Cheney's series there was no constant relationship between blood-pressure readings and the type of cerebral lesions; thus many cases of high blood pressure were thought to have suffered from thrombosis, and several patients with quite low pressures were diagnosed after careful observation as cases of cerebral hæmorrhage.

WILLIAM BEAUMONT AND THE GASTRIC JUICE.

EVERY medical student has heard of the accidental wounding of Alexis St. Martin at Fort Mackinac, on Lake Huron in June, 1822, when a part of his stomach wall and of his left lung were carried away; of his recovery after a protracted convalescence even in the pre-antiseptic days, and of his resultant gastric fistula by which Dr. William Beaumont, the regimental surgeon stationed at the Fort, was enabled to carry out numerous investigations. The results of these were published 11 years later by Beaumont at Plattsburgh (F. P. Allen), and no historical summary on digestion is complete without reference to what is now considered a medical classic. Owing to the rarity of the original editions readers, however, have had to rely upon the accuracy of abstracts of this work by other authors, unless they were fortunate enough to have access to the original work. The Harvard University Press have now brought out a facsimile[1] of the 1833 edition, thus bringing within reach of all medical men this outstanding work of Beaumont. The volume is enhanced in value by the inclusion, as a preface, of a reprint of Osler's address on Beaumont delivered before the St. Louis Medical Society on Oct. 4th, 1902. Osler sketches the life of Beaumont in the United States Army, and traces the career of St. Martin until his death at the age of 75. We are told of his horror of further experiments, of his somewhat ungracious refusal to accede to Beaumont's last plea, in a letter dated Oct. 15th, 1852, to return to him in the interest of medical science, and of the manner in which St. Martin's relatives foiled the attempt to obtain an autopsy. Beaumont's life may be read in a careful and sympathetic study published by Dr. J. S. Myer in 1912, to which Osler again contributed an introduction.[2]

Owing to the uniqueness of Beaumont's experiments too great credit no doubt has often been paid to the results of his researches, and too little to those of his predecessors. Before Beaumont had written, the reaction of the gastric contents before, during, and after digestion had been noted by Carminati and Reaumur, the nature of the acid secreted was determined by Prout and confirmed in England by Children and in Germany by Tiedmann and Gmelin, and an accurate description of the gastric juice had been given by Brugnatelli and Scopoli. It is of interest to note that Berzelius, the famous chemist at Stockholm, was unable to detect any acid in the specimen of gastric contents sent him by Beaumont. Gosse, who could vomit at will, had already determined with an amazing degree of accuracy the digestibility of various foodstuffs, and subdivided animal and vegetable foods each into three classes, according as the stomach could digest them. Beaumont's observations are, however, outstanding in the care and diligence with which he pursued his work. He initiated a completely new advance in gastric physiology. His method of obtaining gastric juice was a distinct advance over the previous attempts such as killing animals, the use of sponges rejected from the stomach, and the employment of voluntary vomiters. The accidental production of a gastric fistula was quickly followed by its experimental production in animals, finally reaching perfection in the Pavlov pouch.

Beaumont anticipated many of Pavlov's results including the influence on gastric secretion of mental disturbances, the relation of the amount of food taken, and the quantity of juice secreted, and the condition of the fasting stomach. He was, however, wrong in supposing that gastric juice could be secreted through the reflex of direct stimulation of the mucous lining of the stomach.

X RAYS IN FILARIASIS.

THE attention drawn by Dr. M. Weinbren[1] to the possible value of X rays in the diagnosis of *Cysticercus cellulosæ* and *Trichinella spiralis* renders opportune a reference to the likelihood of their increased uses in filariasis as suggested by work of F. W. O'Connor, Ross Golden, and Hugh Auchincloss.[2] These writers recall the observations of others that *Filaria bancrofti* may be present, particularly in groin and epitrochlear glands, in large numbers both alive and more or less calcified. On several occasions O'Connor has laid stress on the presence of a small painful area in the distal part of a limb, the pain increasing in intensity with an attack of lymphangitis or elephantoid fever, which was believed to be filarial in origin. He further found that on excision of the skin and subcutaneous tissue comprising such an area in a lymphangitic patient adult filariæ were present in the subcutaneous fat of the excised portion, which, of course, contained no lymphatic glands. After excision symptoms disappeared, and had not returned during a year's observation. It was also noted that in a piece of excised subcutaneous tissue living and calcified worms were frequently found associated, so that the question arose whether the detection by X rays of calcified worms might not be a guide to the situation of living ones. A spermatic cord removed at post-mortem examination was subjected to X rays because microfilariæ were present in the associated hydrocele. Shadows were present in the cord, and were shown to correspond to calcified worms. The way was thus opened for clinical investigation on a woman of 30 who had had attacks of elephantoid fever for 20 years, and in whom elephantiasis was established. She had a tender area on the inner side of the left thigh about 4 in. above the femoral condyle. In this region X rays showed three shadows, each 3–4 mm. long by 1 mm. broad. One lay in Hunter's canal and the other two close together in the subcutaneous tissue on the site of focal tenderness. The skin and subcutaneous tissue comprising this area were excised; as were two other blocks of tissue, one on the front of each leg which had shown local tenderness but no shadows. The results of microscopic examination of part of the tissue from the thigh are reported. Calcified worms were found 1 cm. below the surface, encapsuled in concentrically arranged fibrous tissue; the inner aspect of this capsule showed no evidence of endothelial cells, while the connective tissue round it contained numerous engorged blood-vessels with greatly thickened middle coats. There was no local eosinophilia, nor had previous blood examination detected either blood eosinophilia or microfilariæ.

[1] THE LANCET, 1930, i., 1433.

[2] Amer. Jour. Rontgenol. and Radium Therapy, 1930, xxiii., 494.

Apparently none of the filariæ were alive when excised; at least there is mention only of partly calcified specimens, though this change was not in all cases extensive enough to throw a detectable X ray shadow. In some other cases of elephantiasis reported upon, shadows corresponding to those thrown by calcified filariæ were found in considerable chains. It is clear, then, that numbers of *F. bancrofti* may lie scattered in the subcutaneous tissue or strung out in distal lymphatic vessels. It is also pointed out that even extensively calcified specimens are hard to detect unless the limb has been so arranged that they lie in its profile. Nevertheless, the belief is expressed in the paper that since excision from an elephantoid limb of areas containing living worms has improved symptoms, the X ray demonstration of calcified filariæ may aid in localising the attack on the disease.

AN OFFICIAL CORRECTION FROM THE M.R.C.

PENDING a reply from their American house the Sandoz Chemical Works, Pharmaceutical Department (5, Wigmore-street, London, W. 1), desire us to publish the following extract from the *Pharmaceutical Journal* of Feb. 20th, 1926 :—

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN: THE PHARMACOLOGICAL LABORATORIES.

(Text of a pamphlet which is being supplied to inquirers by the Secretary of the Society, 17, Bloomsbury-square, London, W.C. 1.)

These laboratories are now in a position to test the drugs and preparations dealt with in detail hereafter.

3. *Ergot.*—Samples of ergot will be accepted to be tested in the form of the powdered ergot. The Geneva Conference has made no recommendations in the matter of ergot. The chief active substances which may be present in extracts are ergotamine (or ergotoxin), histamine, and tyramine. It will be assumed that the therapeutically active substance is the specific alkaloid ergotamine, and a test for its amount will be applied to an acid alcoholic extract of the powdered drug.

As standard a sample of ergotamine tartrate is available, prepared by the Sandoz Chemical Works, Basle.

The test applied will be the capacity of an acid alcoholic extract prepared from the sample to reverse the action of adrenaline either on the blood pressure of a pithed cat or on the isolated uterus of the rabbit. After consultation with the Director of the Department of Biological Standards, Medical Research Council, it has been decided to approve as good samples of ergot those containing not less than 1 mgm. per gram of the specific alkaloid.

INSULIN IN OIL.

IN the treatment of diabetes mellitus the ideal towards which the physician strives is to keep the blood-sugar of the patient within normal limits throughout the 24 hours. The attainment of this ideal is often prevented because insulin, as usually administered in aqueous solution, is completely absorbed within eight hours of injection. Several attempts have been made to overcome this difficulty by incorporating insulin with some vehicle which will delay the absorption of the hormone. Some 18 months ago Dr. O Leyton described in these columns[1] some experiments with a suspension of powdered insulin in castor oil, in the proportion of 100 units to each cubic centimetre. He found that the period of absorption was increased to as much as 16 hours and that correspondingly large doses of insulin could be administered in this way without provoking hypoglycæmic symptoms. More recently, M. Labbé, R. Boulin, and H. Goulié have worked on the same lines using olive oil containing 20 units of insulin per cubic centimetre. They examined[2] the blood-sugar curve after 20 units of this suspensic and after the same dose of aqueous insulin, but fou little difference between the two curves. They a observed that in diabetics on a fixed diet the glycosu increased when the oily preparation was substitut in similar doses for ordinary insulin. They conclu that oily suspensions of insulin do not retard abso tion. The results of most other workers, howev tend to support Leyton's opposite conclusic although there is no general agreement concerning t degree of delay which can be obtained. Apart fr this question the use of oil as a medium for su cutaneous injections is not entirely free from objectic Vegetable oils such as castor oil do not usually exc any notable inflammatory reaction in the surroundi tissues, but it is often a matter of weeks before t oil is completely absorbed—an obvious objection circumstances where repeated injections are necessa

MILK FEVER.

THE last of this year's Goulstonian lectures[1] the significance to clinical medicine of studies calcium and phosphorus metabolism was concern partly with the contribution to therapeutics of t researches which Dr. Donald Hunter had describ The use of calcium therapy in tetany, lead poisoni œdema, and acute necroses of the liver was discuss with reference to human patients, and a brief co cluding section noted the work of Prof. H. Drye and Prof. J. R. Greig[2 3] on the milk fever of co At the International Veterinary Congress, held London from August 5th to 9th, Prof. Greig gave historical account of the steps whereby the ætiolo of this curious condition has been elucidated.

Milk fever is a disease of sudden onset which attac milk cows, producing partial or complete prostrati and paralysis of the hind quarters, sometimes a of other parts. Primiparæ are rarely affected. T period of greatest susceptibility in the milking l of an individual cow corresponds to the period f greatest milk secretion. Many hypotheses have fr time to time been formulated to explain the natu of milk fever. On the theory that the cause was infection J. J. Schmidt in 1897 injected into t udders of a series of cases a solution of iodide f potassium, which was at that time believed to ha antiseptic properties. The treatment met w remarkable success, and reduced the mortality fr the disease from 60 or 70 per cent. to 15 per ce Later a modification, devised by Andersen (Skand borg) and others, replaced the injection of flu by mammary inflation, and to-day the mortal is less than 1 per cent. But while a specific c for the disease had been discovered empirically, t cause of milk fever remained a mystery until, 1924, Prof. Dryerre and Prof. Greig began to inve gate the pathology of the condition, starting w the fact that specific cure resulted, no matter whet antiseptic fluids, sterile water, oxygen or air w injected into the udder. They decided that sim distension of the mammæ must act either (1) eliciting some endocrine disturbance, or (2) mechanically retarding or arresting milk secreti and so preventing the loss in the milk of some su stance vital to the organism. It occurred to th that the colostrum of the cow is rich in calciu and that the onset of a profuse lactation mig occasion a rapid reduction in the concentration the blood calcium. This idea seemed to be support

[1] THE LANCET, 1930, i., 526, 897, 947, 999.
[2] Vet. Record, 1925, v., 225; 1928, viii., 721.
[3] Greig, J. R.: Vet. Rec., 1929, ix., 509; 1930, x., 115.

by the further observation that the spastic seizures in the early stages of milk fever were often tetanic in character. Since not every heavy milking cow was subject to the disease some other factor, such as parathyroid dysfunction, was postulated as a predisposing cause.

The story of the gradual confirmation by experimental evidence of this main hypothesis and the disposal of other theories that at one time looked equally probable is a fascinating one. While the blood calcium content of normal parturient or lactating cows is 9 mg. to 11 mg. per 100 c.cm. serum, that of 82 cows attacked by milk fever was found to give an average value of 5·13 mg. The degree of the severity of the symptoms, moreover, bore a distinct relation to the calcium level in the blood, while the blood-calcium concentration in bovine diseases other than milk fever was normal or only slightly below normal. Inflation of the mammæ of normal lactating ewes was found to cause a rise in the blood calcium of about 10 per cent., and finally in 15 cases of milk fever successfully treated by mammary inflation this procedure invariably caused a rise in the blood-calcium value. In Prof. Greig's view the curative effect of mammary inflation may be due to its mechanical effect in preventing the further interchange of calcium from the blood to the gland acini, and also to the forcing back of the calcium, which is heavily concentrated in the gland, back into the blood. This method of treatment, however, is now likely to be superseded by direct calcium therapy. In 1928, when seeking for a bland form of calcium which could be injected without producing local irritation, Prof. Greig found that calcium gluconate (Sandoz) produced little or no irritation even when injected subcutaneously. In a series of over 100 cases of milk fever the great majority have been rapidly and completely cured with a single injection of this preparation, and in only three cases did it fail to produce a markedly beneficial response; in these the technique is blamed. It has also been found possible to abort a commencing attack of milk fever by flooding the blood with calcium upon the first appearance of the symptoms. Observations suggest that the disease may be prevented by commencing a massive administration of vitamin D a few days before calving. The fact that not only milk fever in cows, but lambing sickness in ewes, and transit tetany in mares are all rapidly cured by mammary inflation, and that these are the only conditions, in an examination of over 500 samples of blood, in which an acute hypocalcæmia has been found, suggests strongly that the essential cause of milk fever is an acute blood-calcium deficiency, and that the specific curative action of mammary inflation consists in raising the blood-calcium values.

UNIFORMITY IN RECORDS OF MATERNAL DEATHS.

THE world-wide effort to reduce maternal deaths associated with childbearing suggests that a uniform system of classifying such deaths ought to be devised. British obstetricians have recently drawn attention to the lesser mortality in Scandinavian countries and in Holland when compared with that of England, but we cannot be sure that we are comparing like with like. Even England and Scotland classify these deaths on different methods, so that not even English and Scottish towns can be compared. In the annual reports of medical officers of health noticed on another page it is shown that Derby has a maternal death-rate of 3·7, or of 6·3 per 1000 births, according to the system of classification adopted, and the report from Liverpool points out that the inclusion of 21 additional deaths associated with childbirth would raise that city's rate from 3·5 to 4·6. The Edinburgh figure of 7·0 cannot be taken as comparable with the Liverpool figures. An obvious anomaly in the official method of calculating this death-rate is that although the deaths include those from sepsis and other complications following abortions and stillbirths, the rate is calculated per 1000 live births, instead of per 1000 of all terminated pregnancies. Stillbirths are now registered, but the number of abortions is not known. The figure for all terminated pregnancies is, therefore, not available. It would be possible, however, to keep separate the deaths due to abortion, and in view of the increasing number of these deaths this course appears to be desirable. It is, we believe, already practised in many towns and districts in Germany, and in the departmental committee's report on maternal mortality and morbidity recently summarised in our columns the distinction is made in many of the tables compiled. Excluding the deaths from abortion, it would seem proper practice to record the number of these maternal deaths per 1000 live and stillbirths. The main difficulty appears to be the decision which deaths should be recorded as due to childbirth and which as merely associated with childbirth. It ought to be possible to find a way to state the facts so that maternal mortality of various countries and districts can be compared, and a scheme to this end might well be compiled by some interested body, for example by the Health Committee of the League of Nations.

LONDON COUNTY CORONERSHIP CHANGES.

THE retirement of Sir Walter Schröder and Mr. H. R. Oswald from their coronerships at the end of October will end the public service of two officers who have set a high standard of ability and judicial temper. Sir Walter Schröder had many years of experience as deputy before he was appointed coroner for the central district of the County of London 20 years ago. Past president, and now honorary secretary, of the Coroners' Society, he was at one time in charge of the recent edition of "Jervis on Coroners"; many of the notes in that invaluable book are believed to incorporate his opinions. Mr. Oswald's service, almost as long, is not less distinguished; appointed as coroner for the western district in 1919, he had been coroner for the south-eastern district since 1902. The London County Council has expressed its warm appreciation of the admirable work of these two officers; with this expression all concerned will wish to be cordially associated.

These two retirements are of more than personal interest. The London County Council will now be able to reach a further stage in its reorganisation of coroners' districts. The Act of 1926 abolished franchise coronerships (except the offices of the King's coroner, the coroner of the King's Household, the coroner for the City of London, and the coroner for the Isles of Scilly) as from the next vacancy. Within the County of London the dean and chapter of Westminster have their own coroner who, on their appointment, has been coroner for the city and liberty of Westminster. The Duchy of Lancaster has franchise coronerships in London also, the possessions of the Duchy being by no means limited to the north of England but ranging as wide as the former properties of the great John of Gaunt. The Chancellor of the Duchy can, under the 1926 Act,

relinquish his right of appointment by deed under his hand and seal on His Majesty's behalf. Gradually these franchise coronerships will disappear and the programme of regrouping the London districts will proceed. The London coronerships, becoming whole-time offices with systematic superannuation and compulsory retirement arrangements, will continue to be posts of great importance. As the vacancies are filled it will be possible to see what further requirements are stipulated for by the London County Council beyond the statutory qualification (five years' standing as barrister, solicitor, or legally qualified medical practitioner) laid down in Section 1 of the Act of 1926. A coroner with medical qualifications often possesses the additional legal qualification (perhaps less laboriously attained) of having been called to the Bar. It would not be unreasonable to insist that a barrister or solicitor, before being accepted for appointment as coroner for a London district, should also be able to produce evidence of medical knowledge.

FRENCH MENTAL HOSPITALS.

THE study tours organised by the Royal Medico-Psychological Association are proving of the greatest interest and educational value to those privileged to participate in them. Dr. A. E. Evans has once more benefited the less fortunate majority by writing a description of the latest tour to the department of the Seine.[1] The French Lunacy Act of 1838 provides for admission to asylums voluntarily, on request signed by some relative or friend, and by certificate, signed by a doctor. As the cost falls on the departments and townships, some counties only accept as voluntary patients those who can defray the cost. The certificate applies particularly to dangerous cases and the reception order is made by the Prefect of Police. The patients then go to the admission department of L'Asile Ste. Anne, where a new certificate is made out by the senior physician, and thence to the appropriate institution, where the patients are again certified, a certificate recommending detention being supplied 15 days later. Reports are sent to the Procureur (the public prosecutor) every month, and he visits the patients every six months. Discharge is proposed by the senior physician and authorised by the Prefect of Police. Voluntary patients can leave forthwith on the petition of the person who requested admission or on a certificate of recovery from the senior physician. At the hospital of Henri Rouselle patients enter and leave freely without any legal formality. For children there is a dispensary which functions as a hospital. The recovery-rate for the asylums of the department is 45·6 per cent. and the death-rate 12·3 per cent. for the year 1927.

Dr. Evans describes visits to L'Asile Ste. Anne, the Hôpital Henri Rouselle, L'Asile de Villejuif, Maison Blanche, and L'Asile de Vauclose. The Paris centre for mental prophylaxis consists of a central dispensary for examination, classification, and treatment; a mental hospital for observation and treatment; a social service to follow up cases; a department for home visitation by specially trained assistants; laboratories; an institute of psychiatry and a school of mental prophylaxis for training workers. The International Congress of Mental Hygiene was meeting in Paris at the time of the visit. Among the papers read was one putting forward proposals for the improvement of psychiatry in France. It was suggested that the State should coördinate and contr all activities, and that an advisory national coun for mental prophylaxis and a national institute f training and research should be formed. Ea department would have a centre, on the lines of t one existing in Paris, to include a hospital for dangero patients and another for harmless, long-standing, a curable cases; a hospice or colony run on open-do principles for the incurable and feeble-minded; home for patients who need segregation; a speci establishment for antisocial or criminal patient and facilities for research and the teaching of ment prophylaxis. Home treatment with money paymen would be provided for and particular attention giv to the selection of suitable employment. The pr posals also suggest that the dispensaries should ha advisory functions relating to eugenics, delinquenc prostitution, vagrancy, and immigration.

Occupational therapy, which was such a feature the Dutch mental hospitals visited in 1928,[2] is n extensively used in France. Le Patronage l'Enfance has as its object the protection of orphans children in unsuitable surroundings and of delinquent Every child has a psychological examination, and t principal medical officer of the neuropsychiatr clinic gives directions for future care. Over 60 p cent. of the children are found to have some ment abnormality. At L'Asile de Villejuif there is special section for criminal types of patients, many them high-grade feeble-minded delinquents. D Colin, the superintendent, was specially interested these people and knew of some 200 of them who we improperly housed in prisons or asylums. He w able to open two blocks for men in 1910. Ea patient has a single room with fixed bed and so suitable occupation. Everything is designed prevent the concealment of knives and forks, and t tools in the racks form a pattern which makes t absence of any one conspicuous. At the Mais Blanche, an institution opened in 1900 for wom only, there was an interesting type of impervio floor made of sawdust, magnesite, and magnesiu chloride. Nurses are instructed, and examined written paper and orally in administration, hygie sick nursing, anatomy, physiology, psychology, ment nursing, and pharmacy. The salaries are about 10 francs a month. At Maison Blanche there is a crec for the young children of married nurses; quite number of the nurses are married women. T main impressions summarised by Dr. Evans ar the single portal for all mental patients; the pleasin well-lighted, and ventilated wards; the separa buildings of single rooms for noisy and dangero patients; the lay directorship, which does not see calculated to encourage initiative in medical welfa or pathological research; the well-chosen diet; a the attention given to prophylaxis.

Sir Charles Martin, whose Croonian lectures on t thermal adjustment of man to external conditio we are about to publish, leaves for Australia at t end of the year to take up the position of Director the Division of Animal Nutrition under the Commo wealth Council for Scientific and Industrial Researc This Council is a reflection of the Department f Scientific and Industrial Research in this countr and its laboratories are situated in the grounds the University of Adelaide, field experiments bei conducted in various parts of the continent where a assortment of nutritional troubles are encountered b stock-raisers.

CLINICAL INTERPRETATION OF AIDS TO DIAGNOSIS

A Series of Special Articles, contributed by invitation.

LXXXII.

THE CLINICAL SIGNIFICANCE OF SLIT-LAMP APPEARANCES.

PART II.*

The Conjunctiva.

IN the normal conjunctiva we are able to observe with the slit-lamp the circulation of the blood in the finer vessels, more especially those at the limbus. The nerves may be made apparent. As a senile change, pinguecula may be observed earlier than by other means. In injuries to the eye a small perforation of the sclera by a flying fragment may be suspected when we find a dark subconjunctival hæmorrhage that has arisen from injury to branches of the anterior ciliary vessels. The peculiar cystic appearance of scars after a trephining operation may be examined. It will be found that they are always associated with pigment scattering throughout their walls. In cases of argyrosis the pigment will be seen to be in the epithelial layer of the conjunctiva, likewise the pigmentation seen in siderosis. The pigment in Addison's disease will be seen as patches, in the interpalpebral space, in the conjunctiva only.

The Cornea.

When examining the cornea it is necessary to eliminate the reflex from its surface, in the same way as in ordinary examination in focal light; that is, observation in the direction of the direct reflection of light is avoided. This is achieved by illuminating at a relatively high angle the portion of the cornea to be examined, and making an observation in the direction of the optic axis. The cornea may be examined by transillumination, by the light reflected from iris and lens, and the method of examination in the zone of specular reflection may also be applied. Observations have been made on the thickness of the cornea, and figures obtained by this method are at a variance with those obtained by post-mortem examination. Post-mortem measurements suggest that the cornea is 0·8 mm. to 1 mm. in thickness, whereas the figures obtained during life are from 0·583 mm. to 0·641 mm.

In the normal cornea the optical section, sufficiently narrowed, will reveal that the epithelial layer may be distinguished from Bowman's membrane; that the corneal stroma is not homogeneous. Nerves will be visible, and if the posterior band of the cornea, that reflected by the posterior surface, be examined in the zone of specular reflection the endothelium of the cornea arranged as a mosaic may be seen. An important congenital condition is buphthalmos, and here besides the bedewing (œdema) of the epithelium, we are able to distinguish ruptures of Descemet's membrane, mainly by their sinuous course, bright edges, and absence of endothelium upon their posterior surface of the cornea where the rupture has occurred. Arcus senilis as a senile change is seen earlier than by other means, and a faint haze in the neighbourhood of the cornea will be seen in the optical section. Among important traumatic lesions it is possible to decide whether a foreign body has perforated the cornea, so that it lies partly in the cornea and partly in the anterior chamber. This point is of considerable importance when deciding the means which should be adopted for its removal. A minute examination may be made of the posterior surface of the cornea which will be found powdered over with tiny particles of uveal pigment after a contusion.

Perforating wounds will be distinguished by the fact that folds are produced in the membranes of Bowman and Descemet. Folds of the structureless membranes of the eye have been elucidated by the peculiar behaviour of the reflexes produced. This phenomenon is well exemplified by considering the transparent paper in which it is the habit to wrap soap, food, and chocolate boxes. So long as this paper is perfectly flat it is invisible, but when thrown into folds it produces twin reflexes. The structureless membranes in the eye are the membranes of Bowman and Descemet, the capsule of the lens, and the retina, and all these when folded are visible by the reflexes they produce. In siderosis of the globe the corneal optic section is yellowish in colour. Alterations in the thickness of the cornea are easily appreciated when a narrow optical section is produced. Thinning is usually produced by loss of the anterior surface, as in ulceration, thickening by an infiltration that causes a bulging background of the posterior surface into the anterior chamber, as in disciform keratitis.

BEDEWING OF EPITHELIUM AND ENDOTHELIUM.

Two important phenomena are well demonstrated by the slit-lamp—namely, bedewing of the epithelium and endothelium. These are well seen by transillumination, the cornea appearing to be covered in droplets of fluid. Epithelial bedewing has been well known, for instance, as a condition accompanying glaucoma, but the importance of endothelial bedewing has been shown by means of the slit-lamp. It gives the appearance of much finer droplets than when the epithelium is affected and has been shown to be an early sign in diseases of the uveal tract. The endothelium in these circumstances when it is examined in the zone of specular reflection, shows that the sharp outline of the cells has been lost and that characteristic islets appear. Upon these islets precipitates form, and in this way the earliest stages of deposits upon the posterior surface of the cornea ("K.P.") are detectable.

Little of importance has been shown by the examination of corneal scars. Vascular changes are easily examined, best by transillumination. In this way not only may the superficial and deep vessels be distinguished but the movement of corpuscles may be followed by quite low magnification. In all inflammatory conditions the nerves are unduly prominent. Corneal precipitates are easily examined and their early appearances noted, so that early indications of uveitis may be detected long before grosser precipitates may be seen by the loupes in common use. It is interesting to note that the precipitates which accompany heterochromic cyclitis are always grey in colour. Although pathological pigmentation of the cornea was known before the introduction of the slit-lamp, we are now able to see these changes more regularly. A transverse pigmented line (Hudson's brown line) is seen in certain corneal opacities. Stähli has described a similar line occurring in an otherwise normal cornea. Fleischer's ring is characteristic of conical cornea whose base is

*Part I. appeared last week.

partially or wholly encircled. Kayser's ring is seen in Wilson's disease (hepato-lenticular degeneration) and occurs in Descemet's membrane. A fusiform deposit of pigment grains (Krukenberg's spindle) occurs on the back of the cornea in certain cases of myopia. By means of the slit-lamp our knowledge of conical cornea has been increased and certain small constant features discovered. In Fuchs's epithelial dystrophy changes in the endothelium as the earliest signs have been established. In disciform keratitis the backward bulging of the posterior parts of the cornea is well seen, as well as the frequent localised exudate upon the most prominent part of the bulge. Finally, an early diagnosis of parenchymatous keratitis is possible, even before any injection of the eye has occurred, for the cornea shows epithelial bedewing, cloudy opacities, and localised thickening.

The Anterior Chamber.

The only method of examination that can be used for the anterior chamber is that of focal light. It is possible, however, to examine the aqueous by the beam projected through it, against the unilluminated background. In this way we may see floating particles, uveal pigment, blood corpuscles, and so forth. These particles are seen to be in constant movement, rising in front of the iris and falling behind the cornea. They demonstrate thermal currents in the aqueous, due to the fact that the aqueous in contact with the iris is warmer than that in contact with the cornea. This phenomenon is the explanation of the Erlich-Türk line seen on the back of the cornea after injecting fluorescein into the vein of the rabbit's ear. A deposit of cellular elements, apparently white blood corpuscles, is seen in 50 per cent. of children along this line. The deposit of uveal pigment on the back of the cornea in cases of Krukenberg's spindle is also along this line.

Persistent pupillary membrane is often visible with the slit-lamp and is found to be much commoner than was previously thought. After contusions of the eye pigment granules are seen in the aqueous. In subluxation of the lens a prolapse of vitreous is seen protruding through the pupil, always covered with brown pigment granules. Slight changes in the aqueous are seen early even before actual particles are visible. A change in the constitution of the aqueous is shown by the visibility of the beam of light as it passes through the anterior chamber (flare). Any doubt as to the presence of an anterior chamber after an operation for glaucoma may be easily settled by observing if there is any gap between the light reflected by the cornea and that by the lens or iris.

The Iris.

In the examination of the iris focal light and the method of transillumination may be used, since the iris has behind it a reflecting screen in the lens, especially if it be opaque. It is easy to observe, in irides not too heavily laden with pigment, that the iris consists of three layers; the retinal pigment layer is visible at the pupillary margin, the anterior mesoblastic layer extending from the ciliary border to the collarette, and the posterior mesoblastic layer from the collarette to the pupillary margin. At the junction of the anterior and posterior mesoblastic layers the angle of Fuchs is seen. It is from the collarette that the remains of the pupillary membrane arise and their marked elasticity will be appreciated as the pupil alters in size. The sphincter iridis may be seen in pale irides if the iris be illuminated by a well-focused beam in its immediate neighbourhood on the pupillary side (indirect illumination). The common congenital anomalies are those seen in connexion with partial or complete coloboma. This usually occurs below and when complete the retinal pigment layer will be seen along the edge of the coloboma. When incomplete we may have an aplasia of the anterior mesoblastic layer or merely a pit. In melanosis of the iris the surface of the iris may show an irregular surface and the fact that the iris is hyperpigmented is known by the particles of pigment seen on the sclera at the point of perforation of the anterior ciliary vessels and possibly in the fundus. Senile modifications are commonly seen and consist of atrophic changes and disintegration of the pigment. In atrophy when the iris stroma becomes thinned and loses a good deal of its pattern the iris becomes slaty gray, due to the retinal pigment layer shining through. The sphincter iridis may become unusually visible. Disintegration of pigment is a constant senile change. This may be seen at the pigment border and elsewhere in the retinal pigment layer. The result is that the iris becomes translucent in these situations and the pigment becomes scattered over the surface of the iris, the lens, and the posterior surface of the cornea and may be seen moving in the thermal currents of the aqueous. The suggestion in the past that these changes have a relation to cataract and glaucoma is probably erroneous. In injuries to the eye the iris may be involved, showing ruptures of the pupillary margin or hæmorrhages into the substance of the iris that may be seen only by indirect illumination. Many years after a blow upon the eye the iris may become darker in colour. In perforation of the iris in intraocular foreign bodies the hole may be observed by focal light and transillumination through the sclera when a red glow will appear in the perforation.

Interesting points have been raised in connexion with exudative changes in the iris. Apart from tuberculous and syphilitic nodules, certain other nodules are seen near the pupillary margin, especially in chronic irido-cyclitis. Since similar nodules have been seen on strands of pupillary membrane quite apart from the iris they are apparently of the nature of precipitates. Their transitory nature also tends to support this view. As a result of inflammation atrophic and pigmentary changes are seen in the iris. These are often present in the neighbourhood of posterior synechiæ. In heterochromic cyclitis the iris becomes much paler in colour. Early pigmentary disintegration is seen by transillumination.

CHARLES GOULDEN, O.B.E., M.D., M.Chir. Camb. F.R.C.S. Eng.,

Ophthalmic Surgeon to the London Hospital; Surgeon, Royal London Ophthalmic Hospital.

SUNDERLAND'S MEDICAL SERVICES.—Dr. A. Stuart Hebblethwaite, medical officer of health for Sunderland, has prepared a scheme for the reorganisation of the medical services of the borough in consequence of the transfer of the medical functions of the public assistance committee to the health committee. Dr. Hebblethwaite points out that there is need for a fully developed municipal hospital with the same staff and standard as the present voluntary hospitals which have long waiting lists, growing rather than diminishing. He suggests that the municipal hospital at Highfield should be made a central clearing station for the town, from which all cases requiring hospital treatment could be sent to suitable institutions. This would ensure complete coöperation between the present voluntary hospitals and the municipal hospital and would avoid the overcrowding of the one and the depletion of the other. He further recommends that all surgical operations upon patients in the municipal hospital should be performed there instead of sending them to the voluntary institutions.

SPECIAL ARTICLES

THE CASUAL POOR.

A STUDY OF ECONOMIC AND SOCIAL FAILURE.

THE recent report of the Departmental Committee n the Relief of the Casual Poor [1] includes the result : an investigation by Dr. E. O. Lewis of the types : person who fall into this category. As about 2,000 casuals are relieved in England and Wales n any one night it was necessary to conduct the quiry on some plan which would give representative sults, and for this reason Dr. Lewis and his colleagues sited 15 casual wards in various Welsh and English wns, and interviewed 592 persons in all. It was n investigation, in essence, of those men and women ho have failed economically and socially and the asons for such failure may be either physical infirmity, ental infirmity, temperamental defects, psycho-urosis, criminal tendencies, or merely overwhelmingly lverse environment. To assess the important factor any individual case and during a brief interview as a matter of difficulty, especially as the chief ject was to ascertain the proportion of casuals who uld be classified as persons of abnormal mentality. r. Lewis appears to have given borderline cases both mental deficiency and insanity the benefit the doubt; so that his figure for the incidence of eblemindedness is probably rather low. His diffi-lties were increased by the extremely limited ld of interest, and the ignorance, sometimes iteracy, of many of the casuals, which made the plication of any large number of standardised sts out of the question. The interview was nducted as an informal talk from which it was ssible to make some estimate of the mental capacity; this appeared to be normal a rapid physical examina-n was made of the chest and the man was dismissed. r. Lewis observes that the most cursory physical amination was appreciated as a sign of good faith, hile if the subject had an inkling that a mental vestigation was being made he regarded it as a rsonal affront. As the women in the casual wards re few in number it was decided to include uthwark Casual Ward, where special arrangements e made for the reception of women vagrants in e London County area.

MENTAL DEFECT.

Among the group of 592 casuals investigated, 93, 15·7 per cent., were mentally defective, and from is it was estimated that there are about 1800 mental fectives nightly in casual wards in England and ales. There was a complete absence of imbeciles d idiots, who would have been lacking in even the all degree of intelligence necessary for a vagrant e. The casual with the lowest intelligence examined d a mental age of 7, but most of those who were entally defective had mental ages of 8 or 9. There as a tendency among them to attach themselves to her vagrants of better intelligence, sometimes to eir advantage; occasionally, however, their dis-ility was exploited by an unscrupulous companion. ost of them were subnormal in physique, and showed less foresight than their fellows in the care of their feet; their clothing with few exceptions was below the average of that of most casuals. Among the 50 women examined the incidence of feeblemindedness was slightly higher than among the men.

The impression formed of the mental capacities of most of those who did not fall into the mentally defective group was one of subnormality; men and women of normal or supernormal mentality among them formed a small minority. Such a conclusion, Dr. Lewis points out, should be borne in mind when formulating plans to prevent the social failure of such persons in the future; their inefficiency even as unskilled labourers makes them incapable of retaining a situation long. The total number of insane casuals interviewed was only 32, of whom 20 were cases of senile dementia; the remainder included 2 cases of dementia præcox, 4 of manic-depressive insanity, 3 of toxic psychosis, and 3 of paranoia. In only two cases was the condition so severe as to demand treatment in a mental hospital. Symptoms of some form of psychoneurosis were found in 34, or 5·7 per cent. of casuals, in several of whom the condition appeared to have developed as a sequel of a war neurosis; the commonest form was a state of anxiety, due in many cases to a failure to secure work. Often the adoption of a life of vagrancy appeared to be a reaction of flight from an unhappy environment. Neurotic cases of the psychasthenic type were not uncommon, but hysteria was rare and found for the most part among the women, usually in association with alcoholism. In view of these findings Dr. Lewis advises a periodic medical examination of all casuals by practitioners with an interest in psychiatry.

PHYSICAL DEFECT.

It was impossible in the course of such an investigation to make an exhaustive search for physical defects, but attention was paid to any symptom of which a casual complained, with the result that 43 cases of circulatory disease, 75 of chronic alcoholism, and 27 of diseases of the respiratory system were found. Other common physical disabilities were hernia, varicose veins, failing vision, malnutrition, and minor deformities such as ankylosed joints and spinal curvature, or due to rickets and war injuries. Osteo-arthritis and skin diseases were surprisingly rare. In the absence of suitable tests it was impossible to determine the incidence of venereal disease. A periodic medical examination would prevent the deterioration of slight disabilities into serious conditions, Dr. Lewis considers, and would extend the working life of casuals for several years.

The age distribution of casuals gave 13·8 per cent. under 30 years, 66·6 per cent. between 30 and 60, and 19·6 per cent. over 60. None of the women casuals was under 30, and only one child, a few weeks old, was present in the wards visited; the total number of children belonging to the group, according to the information received, was 35, of whom 8 were in the charge of relatives and 10 were under the care of the poor-law authorities or charitable organisations; no information could be obtained about the remainder. Marriage appears to be rare among casuals, no less than 80 per cent. declaring themselves to be unmarried. When questioned on their employment, 80 per cent. admitted to being unskilled labourers, 15 per cent. had performed some kind of skilled work, and less than 5 per cent. had held clerical positions.

A casual was classified as "habitual" when he had

[1] Ministry of Health. Cmd. 3640. H.M. Stationery Office. p. 99. 1s. 6d. The members of the Committee were Mr. A. Dale, Mr. Douglas Hacking, M.P., Sir Arthur Lowry, r. A. C. Parsons, Mr. A. Paterson, Rev. L. R. Phelps (chair-an), Mr. Arthur Shepherd, M.P., and Mrs. Wintringham, with r. L. N. Ure of the Ministry of Health (secretary).

visited casual wards at fairly frequent intervals for a period exceeding one year, and 81·9 per cent. of the total fell into this class; it was estimated that approximately one-third of habituals were not seeking work. Yet whether judged by moral, intellectual, social, or economic standards, Dr. Lewis finds the vagrants of the casual wards better than large numbers of men and women seen from time to time in common lodging-houses, and advises that no innovation be considered which would have the effect of increasing the numbers in such houses, where owing to less adequate public control the vagrant proves a greater menace to the community. He suggests that there should be closer coöperation in the administration of the lodging-houses and the casual wards.

The Committee's Recommendations.

These follow the opinion of Dr. Lewis in the matter of medical examinations; they suggest that these should be made once a month, but on no fixed day, and should include every inmate of the ward at the time. In addition, the officer in charge of the ward should make a practice of bringing to the notice of the doctor any casual who appears to be ill or mentally disordered. Facilities for bathing should be available for every casual on admission, and his clothes should be handed over for storage, so that the need for searching will disappear; disinfection of clothes should only be carried out when necessary and not as a routine. It is advised that the period of detention should always include two nights unless the casual holds a "vacant ticket" issued by a labour exchange, which indicates that he has satisfied the exchange officer that he is seeking work in the district for which he is bound, and that he has a reasonable prospect of obtaining it. Useful and appropriate work should be available for the casual on the day of his detention, and the committee are of the opinion that this could be best provided by appointing a properly trained officer to supervise and instruct. Accommodation in the wards should include a waiting room, a receiving room, day rooms and grounds for exercise, and a separate sleeping cubicle for each casual. Suggestions are offered for improvements in the dietary by the inclusion of 2 oz. of meat in the midday meal, the compulsory addition of some vegetable other than potatoes, and the complete omission of gruel. Registration of casuals is recommended, and the segregation as far as possible of the younger men from the old habituals. Few constructive proposals are offered for reformative measures, but the committee advise closer coöperation between vagrancy committees, employment exchanges, and voluntary bodies willing and able to accept for treatment vagrants who wish to alter their mode of life; moreover, they recommend that local authorities should be allowed, by subscribing to suitable voluntary bodies, to encourage the formation of training centres or to establish such centres themselves. Coöperation could be effected by means of advisory committees representing the vagrancy committee, the standing joint committee or watch committee, the Ministry of Health, the employment exchange, and the interested voluntary bodies in the area. The coöperation of neighbouring councils by means of vagrancy committees is also recommended. It is hoped that, by giving individual attention to each casual, the man who enters the ward for the first time will be given an early opportunity to reinstate himself, while those suffering from some mental or physical disability will be referred to the appropriate institution for treatment; both measures would have the desirable effect of reducing the numbers in the casual wards.

LISTER INSTITUTE OF PREVENTIVE MEDICINE.

(Continued from p. 1370.)

Department of Biochemistry.

Ossification.—Dr. R. Robison has continued collaborate with Dr. Honor B. Fell, Director of t Strangeways Research Laboratory, Cambridge, the investigation of the development of cartilage a bones of the embryo chick, both in the egg and wh isolated and cultivated in vitro. The work has n been extended to the study of membrane bone, f which purpose the jawbone has been found mo suitable. Experiments on calcification in vitro ha been continued by Dr. Robison, Miss M. Maclec and Miss A. Rosenheim, and the formation of n deposits in slices of the bones of rachitic rats has be investigated under various conditions. Eviden has been obtained of the existence of two mechanis favouring calcification in hypertrophic cartilage, t enzyme mechanism producing supersaturation of t solution by increasing the inorganic phosphor concentration, and a further mechanism favouri deposition of salts from the supersaturated soluti thus formed. In order to gain information on t nature of this second mechanism Dr. Robison a Miss M. Maclean are studying the deposition calcium salts in colloid gels, under conditio similar to those used in the experiments with bo slices.

THE VITAMINS.

Dr. S. S. Zilva has continued his investigation the spontaneous inactivation of the antiscorbu factor, and more light has now been thrown on t cause of the modification of the stability in neut solutions of the vitamin produced by autoclavi active solutions. The investigation instituted ascertain whether a functional relationship exi between the antiscorbutic factor and any other fac or factors in the apple and in citrus fruits has be extended in several directions. The inquiry into t vitamin content of dairy products as influenced environment, breed of cow, transit, storage, a other factors has been continued by Dr. Zilva, M Crawford, and Miss Perry, and a further number controlled samples of butter has been assay Attempts are being made to improve methods vitamin assay.

Work on the isolation of vitamin B_2 is bei continued by Miss Harriette Chick, D.Sc., and Miss Copping. They are endeavouring to prepare co centrations of this vitamin from egg-white, in wh it occurs unaccompanied by vitamin B_1, and fr mammalian liver.

Miss Chick, Miss M. H. Roscoe, and M Copping have made a quantitative study of the h stability of vitamin B_2 in yeast and yeast extra and of its sensitiveness to the presence of alk Their finding that vitamin B_2 is very sensitive alkalies at high temperatures is opposed to the c clusions of other workers in this field (Drummond a co-workers; Reader), who consider that vitamin is stable to the action of alkalies at high temperatu but that yeast contains an additional dietary fact "vitamin B_3," which is heat and alkali-labile.

Evidence that a third, hitherto unrecognised, diet factor exists in yeast has been accumulated in the cours the above research, but the evidence points to its be heat-stable. For example, the growth of young rats "synthetic" diets in which the vitamin B_1 is provided

eter's concentrate and the vitamin B_2 by preparations om egg-white, is inferior to that attained when the latter tamin is furnished by autoclaved yeast products. Further, ie repeated failure experienced, in common with other orkers, in attempts to breed young from rats reared to aturity upon diets which contain all the recognised ecessary B vitamins and other dietary factors also points the existence of at least one unknown factor which is dispensable for correct nutrition.

Search for this unknown substance is being made mong both purified substances and ordinary odstuffs.

Using the methods of assay with young growing ts worked out in this department, Miss Roscoe as extended the work on distribution to green and ot vegetables and has found lettuce, cabbage, and inach to be valuable sources of vitamin B_2, and uch richer in this vitamin than in vitamin B. r. Aykroyd (Beit Memorial Research Fellow), present assisted by Miss Gaffikin, is continuing on larger scale the previous work on the cereals (wheat, e, maize, millet and their constituent parts) with the m of throwing further light on the epidemiology of llagra. Foods rich in vitamin B_2—viz., meat, ilk, eggs, and green vegetables, coincide with those hich have been found most effective in practice for e prevention and cure of this disease.

Cereals as a class, however, are poor in this vitamin. t since pellagra occurs almost exclusively among maize ters and is almost unknown among populations whose aple food is wheat, rice, or millet, the vitamin B_2 content milled maize should be found appreciably lower than that the other milled cereals, if lack of vitamin B_2 is to be cepted as the primary cause of the disease. For it is likely that the association of pellagra with maize could be cidental and due to deficiencies in other constituents of e maize-eaters' diet. Attention is also being paid to e possibility that some toxic factor may be present in aize.

The cereals above mentioned are also being assayed r their content of vitamin B_1 to see if the results e in accord with the vitamin (B_1) theory of the iology of beri-beri. Dr. Aykroyd spent the summer 1929 in Newfoundland and Labrador for the rpose of investigating food deficiency disease among e population. Beri-beri was found to be fairly mmon and to affect chiefly the poorest among the hermen. Clinical observations in Labrador fit ll with experimental evidence with regard to beri-ri. Some investigations were also made on functional ght-blindness, a condition not uncommon in wfoundland and often thought to be associated th faulty diet. It occurred among those whose ts were obviously deficient in vitamin A and lded at once to treatment with vitamin A-containing ods.

Biological Value of Proteins.—Dr. Margaret A. ixsen, in collaboration with Miss Chick, is investigating the biological value of proteins and the possible e played by vitamins B_1 and B_2 respectively, determining the minimum intake of nitrogen cessary to secure equilibrium. A satisfactory hnique has been evolved using the adult rat as perimental animal. The experimental results ggest that both vitamins are required for an onomical use of nitrogen. The effect is, however, indirect one, for absence of either causes a loss of petite. The diminished calorie intake is apparent about 48 hours, by the utilisation of some of the imal's own protein to supply fuel. The power of e rat storage of vitamins B_1 and B_2 would appear be very limited.

Most previous estimations of the biological value of ferent proteins suffer from the defect that an inadequate pply of B vitamins was provided during the observations, materials rich in them also contain enough nitrogen to viate the experiment. In the method used by Dr. Fixsen the necessary B vitamins are administered as concentrates containing only minimal amounts of nitrogen; it is hoped, therefore, to obtain more trustworthy estimations of the biological values of the proteins contained in the commoner foodstuffs than has hitherto been possible.

Carotene and Vitamin A.—The exact relation of carotene to vitamin A has been, and, to some extent still is, problematical. It is quite clear that when vitamin A is derived from animal sources, such as liver-oils or butter, carotene cannot be responsible for the whole vitamin A activity, for there is no apparent quantitative relation between the vitamin A value and the depth of yellow coloration. In plants, on the other hand, the relation between depth of yellow colour and biological activity seems to hold good throughout.

The fact that vitamin A cannot always be carotene has tended to discount the possibility that it sometimes may be. This fact, coupled with Prof. J. C. Drummond's pronouncement that highly purified carotene has no vitamin A value, had caused the subject to be dropped, although the association of carotene and vitamin A activity in plant organs is so striking that it could hardly be fortuitous.

The problem was attacked again recently by Euler, to whom it appeared possible that omission of vitamin D from the basal diet of the experimental rats might have accounted for Prof. J. C. Drummond's failure to find carotene active as a source of vitamin A. After much work and the examination of samples of Prof. Drummond's carotene, Mrs. Smedley Maclean, D.Sc., Miss M. Hume, Prof. Drummond, and Dr. Euler identified the factor causing the discrepancy, and it is now generally accepted that highly purified carotene has the power to function as vitamin A, though it cannot be affirmed with absolute certainty that the activity is not due to the presence, as an impurity, of the colourless substance which represents vitamin A in liver oils. If this is the case, the impurity, it must be supposed, is always present in a definite quantitative ratio, and defies all ordinary chemical methods of separation.

The behaviour of rats during and after the experimental period of testing for vitamin A suggests that there is still some factor or factors, not included in the diet, which ought to be present for growth and development to be normal when vitamin A is added; the absence of this factor or factors mars any long-term dietary experiment and is constantly under investigation, concurrently with the vitamin A tests.

Department of Experimental Pathology.

RATE OF HEAT-LOSS FROM A SWEATING BODY.

Dr. A. J. Canny (Rockefeller Fellow, Sydney) and Sir Charles Martin have completed their investigations into the laws of cooling of moist bodies.

Evaporative, convective and radiant heat losses have each proved to be accessible to experimental determination. A large number of experiments made under varying conditions of atmospheric temperature and humidity and in winds of different velocity have been made. They have shown that a simple, even if lengthy, formula which includes no term that cannot be justified on physical principles, may be used to predict the rate of loss of heat from a given moist body under any environmental conditions. For this prediction only the wet and dry bulb temperature of the atmosphere, the wind speed and the internal temperature of the cooling body need be known. Several constants must be available to allow of a calculation of heat loss, but these are easily obtained in a simple system by a few experiments. In particular it has been shown how the temperature of the evaporating surface itself can be measured. This is a quantity whose value seems so far to have eluded experimenters in this field.

It is hoped that the principles developed will be of general application though the absolute quantities obtained in this investigation are applicable only to the particular system used.

ENDOCRINOLOGY.

Hormones of the Anterior Pituitary.—Active extracts from the anterior portion of the pituitary gland can be made both by acid and alkaline watery solutions.

Dr. V. Korenchevsky finds, in confirmation of Evans's experiments, that the former stimulate the development of the generative organs and the cortical portion of the adrenals, whereas the latter have the opposite effect. At the same time the nitrogen metabolism of animals is reduced below the normal.

Department of Protozoology.

EFFECT OF GAMMA IRRADIATION ON BODO CAUDATUS.

The knowledge of the cultural conditions of *Bodo caudatus* obtained in the course of her previous work has been used by Dr. M. Robertson in an attempt to test the effect of exposure to radium upon the growth of cultures under various experimental conditions.

Bodo is very resistant to the gamma rays and the actual death of a culture has not so far been achieved by exposure to a combination of radon and radium equal to 175–200 mg. of radium (screened with 0·5 mm. of lead sheeting) at a distance of 1 cm. for five days.

Two types of experiment have been tried. In the first an actively growing culture is divided equally between two hard glass tubes. One of these is exposed to radium; the other is not and serves as the control. From these two tubes, plates are made at various intervals under precisely parallel conditions. The growth on the plates is followed by means of sample films made at intervals; the films are stained and the numbers in division and the various phases of division are counted per thousand individuals. A second type of experiment is now being worked out in which the bodos are cultivated upon plates but in such a manner that the plate sequence—of initial lag and active rise of multiplication which drops gradually to a cessation of division with high absolute numbers and a final dying down to low numbers in an almost quiescent state as regards division—is reduced to a minimum, and the bodos, which are moved daily on to a fresh plate, are kept multiplying continuously at an approximately uniform rate.

This work is being carried out in association with Mr. Bernard W. Williams of the Surgical Unit at St. Thomas's Hospital.

Department for the Study and Preparation of Antitoxic Sera.

Experimental Production of Pneumococcal Endocarditis.—Dr. G. F. Petrie's experiments have now furnished clear evidence that recurring blood losses predispose to the production of valvular lesions in highly immune rabbits which are given repeated intravenous doses of living virulent pneumococci. The experiments, as a whole, throw some light upon the pathogenesis of infective endocarditis in man, for they indicate the risk of an infective valvular lesion lighting up in consequence of the leakage of bacteria (streptococci or pneumococci) into the blood stream from a cryptic focus, especially in a patient who is suffering from a secondary anæmia. An acquired immunity to the infective organism does not necessarily interpose a barrier to the lodgment and proliferation of the cocci upon the endocardium.

Poliomyelitis.—A horse has been successfully immunised by Dr. W. T. J. Morgan by repeated intramuscular inoculations with a filtrate of a potent poliomyelitis virus. The serum has been tested on monkeys by Dr. Fairbrother and found to possess antiviral properties comparable with convalescent sera. During the whole course of the immunisation no definite signs of a reaction in the horse were observed. The different serum proteins have been separated and purified by the methods in general use for the concentration of diphtheria and tetanus antitoxins. The examination of a limited number of such preparations makes it appear that a considerable part of the antiviral substance is in the euglobulin fraction. The reconcentrated pseudoglobulin and the serum albumin are apparently free from the protective substance.

MEDICINE AND THE LAW.

The Duties of a Police Surgeon.

It has lately been necessary to make a publi protest against misconceptions as to the duties of police surgeon. Proceedings had been taken in th Manchester City Police-court against a man charge with having been drunk and disorderly and wit having assaulted a tramcar driver. It appeared tha when the accused was taken to the police station h asked for a doctor and that a telephone message wa thereupon sent to the divisional police surgeo The surgeon, it was stated, answered that it was n good his coming. Whatever the answer may hav been, it seems subsequently to have been twisted int a refusal to attend without a fee. The presidin magistrate commented upon the refusal as a breac of the surgeon's duty to the city and as a denial justice to the accused. His remarks received conside able publicity in a Manchester evening newspap that night under such headlines as "Doctor refus to see man—Bench insist on duty to city—Presidi magistrate's stern comments." Next day th magistrate withdrew his observations not unhan somely, explaining that he had spoken under misapprehension and that the police surgeon had be under no obligation whatever to attend in consequen of the telephone message. It was thereupon explain to the magistrate that a police surgeon is not municipal official. He renders his service under agreement. The public has no call upon his service His agreement is that he will attend at the reque and on the instruction of the police to make certa examinations and certain reports and, if necessar to give evidence. Being thus a potential witness f the prosecution, he seems hardly the most appropria person for an accused person to call in as a prospecti witness for the defence. Perhaps in no other count but Britain, where the fairness of quasi-offici witnesses for the prosecution is so conspicuous towar the accused, could it be thought that a division police surgeon was at the beck and call of eve defendant.

The magisterial comments, which otherwise mig considerably have damaged a medical practition both by charging him with laxity and selfishne in the execution of his duties and by prejudicing h reputation with his patients and friends, were th satisfactorily withdrawn and the incident end happily. The misunderstanding as to the poli surgeon has its parallels in the popular misconceptio as to the general practitioner. Not infrequent at coroner's inquests and elsewhere a witness complai that a doctor was summoned and callously refus to attend. Many who in their own persons insi upon a rigid limitation of their hours of daily to look upon the medical practitioner as an automat who never eats or sleeps and who never has public private engagements. A patient can be forgiv for forgetting the claims of other patients. But if peremptory demand for the immediate attendance a doctor is put as a matter of legal obligation, it necessary to say frankly that no such obligation known to the law. Nobody can compel a firm solicitors to accept him as a client, much less to atte him and take his instructions at midnight or Sunday afternoon. Analogy between the legal a medical professions is obviously imperfect owing the difference in the services which each rende But, as a matter of contractual relationship, there is more obligation in the one case than in the other.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

CHANGE IN THE SICKNESS INSURANCE LAW.

By a presidential order which is valid until the new Reichstag either agrees or disagrees, important alterations to the Sickness Insurance Law have been issued. Under the present bad economic conditions in Germany the sick clubs (Krankenkassen) were said to be unable to work under the old conditions, economy being essential. It was pointed out that members often abuse the help to which they are entitled by approaching the Krankenkasse even for imaginary ailments, by inducing medical men to prescribe medicine, or by reporting themselves unable to work in order to get sick pay. The principal items of the new order are that henceforth a member of a Krankenkasse has to pay 50 pf. (6*d*.) for the voucher which entitles him to consult a medical man; hitherto these vouchers were issued free of charge. He has also to pay the same sum to the pharmacy for every prescription. A Krankenkasse is also empowered to give its members higher sick pay, leaving it to them to consult medical men and to buy medicine at their own expense. The Minister of Labour stated in the Reichstag, where the health insurance was lately discussed, that the expenses for that insurance were much higher in Germany than in any other country. At the last meeting of the Aerztetag, where the order has been much criticised, the fear was expressed that the alterations in the law might result in a diminution of the consultations of medical men even in those cases where medical attendance is absolutely necessary. Still more important is a provision that medical officers are to be appointed to supervise the medical men engaged in insurance practice. Those medical officers will have the right to state whether a patient is to be attended at all or is able to work, or whether the treatment prescribed by a medical man is necessary or too expensive. In this way, it is feared, the freedom of the profession will disappear and medical service will be in charge of a corps of salaried medical officers. The Minister of Labour is, moreover, to have the right of cancelling a contract between a sick club and a medical organisation if the expenses of medical attendance are too high. The number of young doctors to be admitted to insurance practice is to be limited still further. The order is the most controversial measure put forward for many years, since it destroys all that has been done for the common good of the profession and the Krankenkassen. Although it is doubtful whether the new Parliament to be elected on Sept. 14th will pass the whole of the order, or whether it will have to be modified, there is undoubtedly a strong movement towards saving money in social insurance at the cost of the medical profession.

HEREDITY OF TUBERCULOSIS.

Dr. Vershuer lately read a paper before the Berlin Medical Society on his statistical and genealogical researches into the heredity of tuberculosis. Dr. Vershuer has attempted to compare twins produced from one single ovum with those produced from two ova. His material consisted of 75 pairs of twins, of whom 19 were from one ovum; of the other 56 pairs, 38 were of the same sex and 18 of different sexes. At the time of the research tuberculosis was manifest in one or both of the twins in 42 pairs, symptoms of healed tuberculosis were found in 19 pairs, and no symptoms of the disease were present in 14, although the twins came from a tuberculous "milieu." The twins were divided into three groups: (1) those where both showed the same liability to tuberculosis—to this group belonged 25 pairs; (2) those where one had a passing tuberculosis, or where tuberculosis had affected them both, but at quite different periods of life, or where disease was manifest in different organs, or though affecting the same organ, the prognosis was very different; (3) those where one of the twins had already died, while the other was still healthy. In the twins produced from one ovum it was found that tuberculosis of the same intensity became manifest in the same organ, and even if the twins were separated one from the other and lived in different places; while in the two-ova twins of the same group no case was found where the disease had the same characteristics. In the one-ovum twins liability to tuberculosis differed only until the age of 18 years; in the two-ova twins the difference increased with the age without external causes being responsible. In one-ovum twins the liability to tuberculosis and the similarity of symptoms were much greater than in two-ova twins. Dr. Vershuer concludes from his observations that heredity is an important factor in the pathogenesis of the disease.

MEDICAL EXAMINATION OF MOTOR-CAR DRIVERS.

Dr. Franz, of the Institute for Legal Medicine, holds that licensed motor-car drivers should be examined not only before the licence is granted, but periodically. Beginning at the fortieth year of age, such examination should, in his view, be carried out every second year. In this way the beginning of general paralysis, alterations of the blood pressure, or senile phenomena might be ascertained. After every accident the motorist should be examined with special reference to his mental functions. If an accident is suspected to be due to inebriety he suggests that the blood of the driver and his victims should be examined in a medico-legal institute in order to ascertain the quantity of alcohol present.

DEATH OF PROF. FÜRBRINGER.

Prof. Paul Fürbringer, whose rules for prolonging life based on his own experiences were mentioned in these columns last year,[1] has died in Berlin at the age of 81 years. He was for long chief physician to the Friedrichshain Municipal Hospital; he resigned that appointment some years ago but continued in private practice, and was a recognised expert in medico-legal work; the generally adopted method of cleaning the hands before surgical operations by washing them in a mixture of alcohol and sublimate of mercury was based on his bacteriological research, and was first recommended by him. Fürbringer's vitality was enviable; he indulged in walking, swimming, skating, and mountaineering until recently, notwithstanding his advanced age. He was a genial man and much liked by the profession in Berlin.

THE LÜBECK DISASTER.

The number of deaths in Lübeck as a sequel to mistakes committed in the Calmette treatment has reached 62. The judicial prosecution of the physicians of the general and the children's hospital respectively and of the medical director of the Lübeck Health Office is still in progress.

[1] THE LANCET, 1929, i., 844.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

INFANT PROTECTION IN HUNGARY.

At the recent meeting of the Budapest Royal Medical Society Dr. Nikolas Pfeiffer spoke of the exceedingly low birth-rate in Hungary in the post-war years, and of the measures whereby the level of population could be maintained. One method was by lengthening the average duration of human life; another method was in the improvement of the living chances of the groups most exposed to the risk of death, such as new-born infants. For the reduction of neonatal mortality, which is high in Hungary, the means suggested are greater antenatal and intranatal care. The insurance of motherhood should be extended, and not only more direct material assistance but a thorough reform of the midwifery service is essential. The organisation for the protection of infant and mother should be expanded to cover the agricultural class, which at present is left out. Among the postnatal schemes the injection of B C G is advocated. A defect in the present organisation is the lack of elasticity. Local schemes should be assisted and supplemented not according to the size of the population but to the rate of infant mortality in the district concerned.

THE RELIABILITY OF CANCER STATISTICS.

According to a lecture given in the Medical Society of Budapest by K. Wolff, the method of preparing cancer statistics should be revised. The only reliable statistics are those founded on diagnoses established in vivo, post-mortem protocols, on histological sections, and, finally, on the data afforded by compulsory death certificates. Unsupported clinical diagnoses of cancer, according to calculations, are erroneous in 20 to 40 per cent. of cases and, therefore, exact statistics cannot be expected without histological controls. The verdicts of coroners, some of whom are not medically qualified, are quite unreliable. Thus statistics which appear to prove the increase of cancer mortality may indicate only the development of the science of medical diagnosis; whereas cancer mortality rises in such statistics, the number of cases labelled senile marasmus, unknown disease, and other indefinite diagnoses decreases. Nowadays all well-trained doctors know that nobody dies solely from senile debility. If the patient had no other disease he would be certain to have had myocardial degeneration or a broncho-pneumonia. Post-mortem statistics are also unreliable, because they do not reflect the conditions of the whole population, but of the hospital class. This objection holds true still more with regard to the statistics based on histological material alone. The fewer the cases utilised in the compilation of cancer statistics, the less reliable are the results. In one hospital the leading surgeon may have a predilection for cancer cases; hence the cancer turnover is high. Another hospital hardly admits cancer patients, because its surgeons work on other lines; the number of cancer cases here will be low. Such sources of errors can be eliminated by the collation of the material of many hospitals, when those which have large children's departments will serve to balance others dealing almost exclusively with cancer cases. Thus a fairly accurate picture of the conditions of population could be obtained, but only of the hospital class. The statistics hitherto published do not prove, in Dr. Wolff's opinion, the assumption that the rate of mortality from cancer shows a rising tendency. A relative rise is the obvious corollary of the fact that the number of deaths from other curable and preventable diseases is diminished. But this means no more than that we are at present unable to defend ourselves against cancer, because we know neither its cause, its therapy, nor its prophylaxis. The average duration of life is increasing steadily all over the world. Cancer is the disease of elderly persons. If the average duration of man's life increases, then there are more elderly persons—that is to say more people reach the age at which cancer is apt to occur. It may well be that the number of cancer cases shows considerable increase with the rise of the average duration of life. In Dr. Wolff's view the apparent increase in the incidence of cancer has been too much emphasised. The mortality-rate of every disease displays some oscillations if we comparatively scrutinise the statistical material available over several years. Wolff protests against the interpretation of what may be only natural oscillations as a progressive rise in incidence.

At the same meeting Dr. Ö. Zalka also expressed the opinion that the mortality statistics of cancer leave much to be desired. According to his observations the error in cases of gastric cancer is 31 per cent., in uterine cancer 7 per cent., in rectal cancer 19 per cent., and in œsophageal cancer 130 per cent. The statistics collected by him show no progressive increase of cancer, its occurrence being fairly constant. For instance, between 1919 and 1923 among the autopsies in the Budapest University Clinics on patients over 20 years of age the cancer rate amounted to 12·4 per cent., while between 1924 and 1928 it amounted to 12·52 per cent. Since in quite recent years a larger proportion of different sections of the population seek relief in hospitals, and are subjected to routine post-mortem examinations, he believes that the data provided by post-mortem statistics to-day are nearer to reality, and more nearly representative of the truth, than the older statistics.

THE NERVOUS AND MENTAL INDICATIONS FOR ARTIFICIAL ABORTION.

Dr. P. Büchler, of the Budapest University, holds the view that artificial abortion is indicated in case of severe reactive depression, when the patient displays obstinate resistance against taking nourishment, or if she develops suicidal tendencies. Even in these cases institutional treatment must first be tried, and abortion is indicated only if this treatment is not practicable. In an institute resistance to food can be defeated by the application of forcible feeding and suicide can be prevented by careful watching, but even in institutions the pregnancy may have to be terminated. Most difficult is the problem of schizophrenia. Although it is beyond dispute that the reproduction of schizophrenics is undesirable our efforts must be directed to the prevention of gestation rather than its interruption. There are no definite general indications in psychiatry, but in psychopathies arising from severe intoxications and infections, and in certain cases of paralysis, interference is justified, and, at any rate, danger to the life of the mother can be avoided. As a rule, when a psychosis is suspected Dr. Büchler recommends the conveyance of the patient to a mental hospital where the physician in charge can take what action he deems necessary. The sphere of neurological indications is also narrow. Severe cerebral and spinal diseases form absolute indications for abortion. Disseminated sclerosis is an important one, because this disease tends to progress after childbirth; palsies, ataxia of a greater degree, and the quick loss of

strength may follow. This holds true also for locomotor ataxia, inasmuch as after childbirth ataxia increases and bladder and intestinal troubles may supervene. That spinal and cerebral tumours, syringomyelia, progressive spinal muscular atrophies, hereditary chorea, lateral sclerosis, and severe forms of epidemic encephalitis form absolute indications is beyond dispute. In doubtful cases Dr. Büchler holds that social and eugenic considerations may be allowed to influence the decision, but only in minor degree.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

EPIDERMOPHYTOSIS.

THIS disease, which is also known by a host of pseudonyms such as "athletic foot" or "swimming-pool itch" is believed by many dermatologists to have taken first rank among skin diseases in this country. It is supposed to have been imported by American soldiers returning from the war. Probably the majority of regular habitués of gymnastic halls are now infected with this distressing parasite. It abounds in schools and colleges and seems to be spread especially in damp places such as shower baths and swimming pools. One measure of prophylaxis that has been suggested is to arrange for bathers to soak the feet in 15 per cent. solution of sodium hyposulphite before putting on their shoes and stockings. The following recommendations have been issued by the New York State Department of Health.

1. Inspection of the feet and toes of all bathers and exclusion of those showing infection. The disease may show around the base of the nails or between the toes as a raw open sore or as small or large blisters, or it may resemble eczema.

2. As the fungus will grow readily on silk and cotton goods, leather and probably on damp wood, all equipment such as benches, stools, diving boards, steps, rubber mats, and floors should be washed daily with a strong solution of chlorinated lime or soda. Canvas mats or pads should be abolished.

3. Prevention of exchange of unsterilised towels, suits, or bathing slippers.

POISONOUS PROPERTIES OF MAPLE SUGAR "SAND."

The New York State Department of Health has recently examined and reported on samples of maple sugar "sand" to the consumption of which the death of two children in the State had been attributed. The children had found an old can containing some of this chalk-like substance, had filled the can with water and drunk the solution. They developed a violent gastro-intestinal inflammation with profuse stools containing blood, marked prostration, and rapid lowering of body temperature before death. The sample of "sand" examined in the State laboratories was obtained by filtration of freshly made maple syrup. It was found to be a complex substance consisting mainly of calcium malate. Since magnesium malate is known to produce severe diarrhœa in adults in doses of 9 g. or more it seems probable that calcium malate was the poison responsible for the children's deaths.

HEALTH WORKERS TO TOUR MEXICO.

The American Public Health Association is to hold its annual meeting this year at Fort Worth, Texas, from Oct. 27th to 30th. At the close of the conference a special tour of Mexico is to be undertaken by invitation of Dr. Rafael Silva, the chief of the Mexican Health Department, with the approval of the President of the Republic who has invited the delegates to visit him in his historic castle. A special train will be at the service of the delegates.

INSANITY AND THE LAW.

The degree of responsibility of a criminal cannot be settled, it is now admitted, either by definitions or by a board of experts; there will always be honest differences of opinion which cannot be subjected to any scientific test. The important matter is not a philosophical conception of free will, but a practical question of the future behaviour of the criminal. Let the jury decide, then, whether or no the prisoner at the bar actually committed the crime. The prisoner is then to be studied by a board of experts with a view to prescribing treatment for the correction of his anti-social behaviour and the protection of society. The following five principles have been adopted both by the American Bar Association and, at its recent meeting, by the House of Delegates of the American Medical Association. 1. That there be available to every criminal and juvenile court a psychiatric service to assist the court in the disposition of offenders. 2. That no criminal be sentenced for any felony in any case in which the judge has any discretion as to the sentence until there be filed as a part of the record a psychiatric report. 3. That there be a psychiatric service available to every penal and correctional institution. 4. That there be a psychiatric report on every prisoner convicted of a felony before he is released. 5. That there be established in each State a complete system of administrative transfer and parole, and that there be no decision for or against any parole or any transfer from one institution to another, without a psychiatric report.

AUSTRALASIA.

(FROM OUR OWN CORRESPONDENT.)

THE PRIMARY FELLOWSHIP EXAMINATION.

THE College of Surgeons of Australasia have officially announced that they have received notice that the College of Surgeons of England will hold a primary Fellowship examination in August, 1931. The examination will be held in Melbourne, presuming that not less than 25 eligible candidates are found desirous of being examined. There is no doubt that all who can will take advantage of this opportunity, but even under the present arrangements distance is still a factor. Melbourne is the most central city for the purpose, but it is still a long way to come from outlying parts. Many have expressed some disappointment that it has not been possible to arrange for the papers to be set concurrently in Adelaide, Melbourne, and Sydney, and for the viva-voce examinations to be held in each city separately. It is understood that this suggestion was made to the Australasian College, and no doubt there were good reasons why it has not been accepted. Nevertheless, such a scheme would give more prospective candidates an opportunity to take the examination.

BROKEN EXPLORATORY NEEDLES.

It was something of a coincidence that the issue of THE LANCET with recommendations about the breakage of hypodermic needles (May 17th, p. 1083) should have arrived in Sydney during the progress of an action, the result of such a mischance. This action was one of more than usual interest, because the doctor had not disclosed to the patient the fact that the needle had been broken. The patient had two brothers who were doctors, and the broken needle was accidentally discovered by X rays. Briefly the facts of the case are as follows. The plaintiff alleged that on Friday, Jan. 30th, 1928, the doctor was performing an exploration of his chest, broke, or allowed to break the needle he was using, but did not

in the after-care of his patient take appropriate steps to guard against the harm which might have been caused by the presence of the needle. The action was attributed to negligence, and it was further alleged that the fact that the doctor concealed the presence of the broken needle from the patient also amounted to malpractice. Subsequently the needle had caused the plaintiff suffering and financial loss. An operation for empyema was performed about an hour after the exploration. The evidence showed that the patient was suffering from bronchiectasis. The defence was an admission of the accident but a denial of negligence. It was stated that the needle had broken off during a fit of coughing whilst the doctor was emptying pus from the syringe. The doctor contended that it is impossible to tell a faulty needle by its appearance, and further that the present condition of the patient was the result of bronchiectasis. Numerous expert witnesses testified that in its present position the needle was doing no harm. The reasons given by the doctor for not telling the patient, X raying him, or attempting to remove the needle, were that in the serious condition of the patient it would have been unwise to have informed him or his wife of the accident, that as he felt certain it was doing no damage he took no further steps in the matter, and further, that operation for removal of the needle would have been harmful.

The jury in their verdict found that negligence had been proved and awarded the plaintiff costs at £100. There is no doubt that the fact of the doctor not disclosing the breaking of the needle weighed heavily against him. A number of questions concerning broken needles arose during this case: the responsibility of the doctor for the use of an unsound needle, the propriety of not telling the patient that the needle had been broken; if the fact is disclosed, when and to whom it should be disclosed in the case of a patient who is seriously ill; the responsibility of the doctor for taking steps necessary for the recovery of the needle or to guard against possible harm caused by its presence.

PUBLIC HEALTH SERVICES

RESULTS OF ARTIFICIAL LIGHT TREATMENT FOR TUBERCULOSIS.

By G. Lissant Cox, M.D. Camb.,
CENTRAL TUBERCULOSIS OFFICER, LANCASHIRE COUNTY COUNCIL.

THE following brief account of treatment by artificial light is based on a report for the year 1929 presented to the Lancashire County Council. Light centres have been established at 12 of the 24 tuberculosis dispensaries in the administrative county. Treatment at each dispensary has in the great majority of cases been given by two carbon-arc lamps (Sunrae pattern) for general treatment, and one Kromayer mercury-vapour lamp for local treatment. For obstinate cases it has been found helpful to resort to ancillary forms of treatment, such as curetting, cauterising, aspiration, or application of ointment.

Summary of Results.

1. Artificial light treatment, undertaken at dispensaries by the tuberculosis officers and tuberculosis health visitors, has continued in 1929 to give satisfactory results, particularly in regard to patients suffering from tuberculosis of the skin and tuberculous adenitis with abscess formation and skin involvement, which conditions are very slow in yielding to other forms of treatment.

2. Of the total patients attending light centres, 77 per cent. were able to continue their normal occupation during the course of treatment.

3. 30 per cent. of the patients treated during the year were assisted by the payment of their railway, 'bus, or tram fares to the dispensary light centres.

4. In regard to the 60 skin cases which became "quiescent and apparently cured," the average duration of the disease before the patients commenced light treatment was 10 years 8 months, whereas the average duration of light treatment was 10½ months.

5. For the 252 cases which became "quiescent and apparently cured," the average duration of the disease before the patients commenced light treatment was 4 years 8 months, whereas the average duration of light treatment was 9 months.

6. The average cost of artificial light treatment at the 12 centres amounted to 4*s*. 6½*d*. per patient per week.

RESULTS OF LIGHT TREATMENT IN 1929.

Form of tuberculosis or part of body affected.	Cases on treatment on Jan. 1st, 1929.	Cases commencing treatment in 1929.	Condition of patients whose treatment concluded in 1929.				Ceased treatment for other reasons.*	Still under treatment
			Quiescent an apparently cured.	Improved.	Stationary.	Worse.		
Skin (lupus and scrofuloderma)	167	109	60	12	2	1	35	16
Adenitis with abscess formation and skin involvement	87	133	87	6	—	—	21	10
Adenitis without softening	57	99	55	9	3	—	31	5
Bones, joints, and spine	56	41	26	5	5	—	24	3
Abdomen	12	30	13	1	2	1	6	1
Other non-pulm. conditions	17	12	10	1	1	—	4	1
Pulm. tuberc.—								
Lungs—								
sputum pos.	1	3	—	—	1	—	—	
sputum neg.	—	2	—	—	—	—	—	
Bronchial glands	—	4	—	—	—	—	2	
Pleura	1	1	—	—	—	—	—	
Pulm. and non-pulm. tuberc. combined	5	5	1	—	—	1	6	
Total for 1929	403	439	252	34	14	3	129	41
	842							
For comparison, the total in 1928 was	153	573	190	23	10	1	99	40
	726							

* Includes: (1) any patient who did not receive two months' treatment; (2) patients ceasing light treatment prematurely, e.g., removals, unwilling or unable to continue; and (3) patients transferred to sanatoria or hospitals.

7. Of the 252 cases concluding treatment in 1929 on becoming "quiescent and apparently cured" the consultant tuberculosis officers would normally have recommended 211 for treatment at hospital. Based on the average duration of treatment of such cases, the cost would have been not less than £478, whereas their treatment at the dispensary light centres actually cost (all inclusive) £2240—a saving of £2552.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are 1929 statistics of Edinburgh and three English county boroughs :—

Name of district and estimated (R.-G.) mid-year population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Infant and neonatal mortality.	Young child (1–5 yr.) mortality.	Maternal mortality from childbirth.
Edinburgh .. (427,538)	17·1	15·1	1·10	1·77	2·6	2·2	80/35	39	7·0
Liverpool .. (872,802)	21·6	15·1	1·46	1·27	4·2	1·3	96/30	74	3·5
Coventry .. (172,000)	14·2	11·5	1·03	1·24	2·7	1·7	73/32	55	4·1
Derby .. .. (140,500)	19·0	13·5	0·87	1·46	2·7	2·7	64/27	34	3·7

Stillbirths per 1000 live births: Edinburgh (notified) 5·6, Liverpool, 4·0, Coventry 4·0, Derby 4·4.

Edinburgh.

Dr. William Robertson's report shows that Edinburgh is tackling energetically a tremendous problem of housing and slum clearance. The houses in the city number 107,704 and include 7233 one-roomed and 32,298 two-roomed dwellings. The municipal houses provided up to the end of the year numbered 5758, of which 866 had two rooms, 4502 three rooms, 252 four rooms, and 138 five rooms. Four slum clearance schemes affecting 2359 houses and a population of 7048 have been completed, including the first section of the St. Leonard's scheme. In 1929 no deaths occurred from measles, although 338 first cases were reported. The outbreak of influenza lasted seven weeks and at the peak caused general death-rates of 32·9 and 29·2 in the first two weeks of February. Since 1898 the cancer death-rate for both sexes has gone up from 0·8 to 1·8. The 76 notifications of enteric fever included a mild outbreak of 30 cases of paratyphoid B with no deaths, which appeared to be associated with the milk from one dairy. The ultimate source of infection could not be traced. Diphtheria was unusually prevalent but the case fatality was much lower in 1928 and 1929 than in previous years. The aspiration method of treatment was tried in a few laryngeal cases and a more extended trial will be made with an electric suction pump. The case fatality of scarlet fever was only 0·3, the lowest ever recorded in the city. Anti-toxic serum was administered in 38·6 per cent. of the 938 patients admitted to hospital. There is need for more hospital accommodation for advanced cases of tuberculosis. The mortality-rate of the 149 puerperal fever cases was 16·7 per cent. Dr. W. T. Benson, resident physician to the isolation hospital, asks for more observation wards for doubtful cases.

The bacteriological examination of the water of the swimming baths confirms the Ministry of Health's (August, 1929) report that all swimming baths should be fitted with a filtration plant, which constantly filters and chlorinates the water. Dr. David Lees notes a marked increase to 54 in the percentage of cases of syphilis presenting themselves at an early stage. He records a decrease in congenital syphilis, attributed to the treatment of the mothers during pregnancy.

Of 17 cases of gonococcal ophthalmia 11 were from Edinburgh and 6 from outside areas; of these latter, 2 cases were sent into hospital at the age of 1 month with one eye already irreparably damaged. As a rule the adulteration of milk is small in degree, but in June 40 gallons of "morning" milk and 30 gallons of "evening" milk were sent into the city by motor from a farm in Lanarkshire. The "morning" milk was 20 per cent. deficient in fat and contained 24 per cent. of added water; the corresponding "evening" milk figures being 14 per cent. and 26 per cent. The defence of the consignor was that the cows had been out on grass of a very poor quality and were not receiving artificial food, whilst in addition a leakage had been detected in the milk cooler. He was convicted and fined £8. During the year 39·4 per cent. of the dairy cows slaughtered at the abattoir were affected with tuberculosis in some degree. The Victoria Hospital tubercle-free herd passed successfully through its two six-monthly tests; and the associated grazing farm in Peeblesshire used for raising young stock has also been kept tubercle-free. The municipal dairy herd kept for the supply of the city hospitals was also maintained in a tubercle-free condition. The percentage of tuberculous milk coming into the city from outside has been lower during the past three years.

Liverpool.

Dr. A. A. Mussen says that the excess of mortality caused by the influenza epidemic chiefly occurred at ages 65 and upwards. Concurrently with the influenza there was an extensive outbreak of measles, and towards the end of the year both scarlet fever and diphtheria became prevalent, taxing the accommodation at the City hospitals. There were 3989 notifications of scarlet fever with 41 deaths—a case fatality of 1·0 per cent. In one school containing about 250 children immunisation was carried out with satisfactory results. The notifications of diphtheria numbered 2336 with 139 deaths, a case fatality of 5·9 per cent. The attack-rate from diphtheria is persistently higher in the outer wards probably owing to the more complete notification of the milder cases. The death-rate is usually highest in the central wards, but in 1929 it was highest in the middle ring, the children having been attacked at an earlier age.

Suicides from gas poisoning showed an increase to 49 compared with an average of 24 for the previous four years. The accidental deaths due to this cause numbered 9. About 65 per cent. of the births are attended by midwives, who coöperate well with the antenatal clinics. There are 28 of these at 15 centres conducted by consultant obstetricians. The new cases which attended during 1929 numbered 11,454 and the total births were 18,888. Dr. Mussen points out that in addition to the 66 maternal deaths, which gave a rate of 3·5, there were 21 other deaths of mothers associated with childbirth, which would bring up the rate to 4·6. The Seamen's V.D. clinic has again demonstrated its value. The new cases of syphilis show a slight decline, the figures for the last three years being 459, 435, and 413; whilst the new gonorrhœa cases show an increase, the figures being 931, 1031, and 1112. Very few gonorrhœa cases come up for treatment at an early stage, and the figures show that 25 per cent. of the syphilis cases appear for treatment in the pre-Wassermann stage, 24 per cent. with primary sore and positive Wassermann, 8 per cent. during the secondary stage, and fully 40 per cent. in the stage of later or latent syphilis.

The bulk samples of city milk examined numbered 327, of which 13, or 3·97 per cent., were tuberculous. Of 197 samples of fresh milk supplied to the city hospitals tubercle bacilli were found in 5, and of 337 samples of milk supplied to maternity and child welfare institutions, 4 were tuberculous. Insanitary houses at the end of the year numbered 1868, 1362 being court houses and 506 front houses contiguous to them.

The want of alternative accommodation in the central area bars rapid progress with improvement schemes, or the enforcement of closing orders. The confirmation by the Ministry of Health of the Queen Anne-street improvement scheme comprising 5¾ acres in the central area was recorded last year but

was quashed in the Court of Appeal. The new municipal dwellings in the suburbs now number 18,201 and 169 flats, and 897 more houses are in progress.

Coventry.

Dr. Arthur Massey submits the report for the last full year's work of Dr. Snell, who retired on Jan. 31st, 1930, after more than 30 years administration of the office. The general death-rate was the highest since the great influenza year of 1918, and although Coventry did not suffer as badly as some districts, there was also a marked rise in infant mortality due mainly to respiratory diseases. The continuance of diphtheria was also a disquieting feature. There were 431 notifications and 37 deaths, a case-fatality of 8·6 per cent. Immunisation was begun and 1171 school-children were protected. If this work is to have an appreciable effect, says Dr. Massey, it will need to be undertaken on a much larger scale than the general parental attitude of to-day permits. The housing problem is made more difficult to solve by the rapid growth of the population. Dr. Massey would like to see use made of Section 3 of the 1925 Act, which gives the corporation power to do the work of reconditioning in the owner's default. Dr. Massey mentions some of the industries of Coventry which reflect the trend of modern life. They include motors, airplanes, artificial silk, electrical industries, printing, watch making, machine-tool making, and general engineering. The town is surrounded by a ring of fine commons and atmospheric pollution is less than in many industrial towns. The small river Sherbourne traverses the city from west to east and is much polluted by refuse. It has to be periodically cleaned. Flooding has been troublesome in low-lying districts and is to be prevented. A new sewage disposal plant by bacteria beds at Finham is in progress. The bacteria beds and activated sludge unit at the old sewage farm will also be retained.

Derby.

Dr. Gordon Lilico submits the report for Dr. Brindley's last year of office, owing to the latter's indisposition. He states that the very young and the very old formed the greater number of the influenza victims. Towards the end of the year scarlet fever became very prevalent and overtaxed the accommodation at the isolation hospital. The report from the V.D. clinic at the Royal Infirmary shows increased attendances. There were 77 notifications of small-pox and one death. The fatal case was a male aged 61, vaccinated in infancy, who died before admission to hospital, the cause of death being certified as "pneumonia, influenza, small-pox." The midwives attend about one-third of the confinements. There is a wide difference in the maternal mortality according as one uses the local or the Registrar General's classification of the deaths. The former allocates 4 deaths to puerperal sepsis and 13 to other accidents, &c., while the latter gives 5 deaths to puerperal sepsis and 5 to other accidents, &c. The maternal mortality is, therefore, either 3·7 or 6·3 per thousand births. Of 54 samples of milk examined for tubercle, seven were found to be infected. In each case the milk came from farms in Derbyshire, and six diseased cows were found and slaughtered. At one farm no diseased cow was found.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED AUGUST 9TH, 1930.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 86 (last week 70); scarlet fever, 1501; diphtheria, 976; enteric fever, 82; pneumonia, 461; puerperal fever, 45; puerperal pyrexia, 120; cerebro-spinal fever, 14; acute poliomyelitis, 15; acute polio-encephalitis, 1; encephalitis lethargica, 12; dysentery, 13; ophthalmia neonatorum, 99. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on August 12th–13th was as follows: Small-pox, 209 under treatment, 2 under observation (last week 218 and 10 respectively); scarlet fever, 1750; diphtheria, 1917; enteric fever, 41; measles, 191; whooping cough, 78; puerperal fever, 17 (plus 10 babies); encephalitis lethargica, 119; "other diseases," 24. At St. Margaret's Hospital there were 10 babies with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was one death from small-pox, 3 (1) from enteric fever, 14 (8) from measles, 3 (0) from scarlet fever, 11 (1) from whooping-cough, 26 (5) from diphtheria, 45 (5) from diarrhœa and enteritis under two years, and 10 (1) from influenza. The figures in parentheses are those for London itself.

The death provisionally classified to small-pox was assigned to Islington (metropolitan borough); in addition a death belonging to Wallasey (C.B.), which occurred outside that area during the week ended July 26th, is now reported. The deaths from enteric fever outside London were reported from Reading and Grimsby. Three deaths from diphtheria were reported from Liverpool, 2 each from East Ham, Nottingham, and Bradford. Manchester reported 5 deaths from diarrhœa, Liverpool and Tynemouth each 3, West Ham, Warrington, Hull, Gateshead, Rhondda, and Swansea each 2.

The number of stillbirths notified during the week was 288 (corresponding to a rate of 47 per 1000 births) including 55 in London.

REPORTS OF SCHOOL MEDICAL OFFICERS.

—	No. on roll.	Average attend-ance.	Routine inspec-tion.	Special exams. and reinspec-tions.	Percentage of defects.
Derbyshire..	75,235	—	23,191	8,479	26·1
Hull	47,065	42,212	14,268	51,977	23·1
Warrington .	13,253	11,534	4,178	4,928	15·34

Derbyshire.

Dr. W. M. Ash reports that the work has continued on similar lines to those of the past four or five years; coördination of the various medical services being maintained; the assistant school medical officers are responsible for the child welfare centres in their areas and the school nurses, with few exceptions, are also the health visitors. The orthopædic scheme has been developed; a full-time orthopædic surgeon now attends each of the ten clinics scattered throughout the county and the number of children attending them has risen from 920 in 1928 to 1114 in 1929. Bretby Orthopædic Hospital has been extended by the addition of a 50 bed open-air block which was ready for admissions in January, 1930. Dental work shows progress and considerable increase in numbers attending, though there was a small decrease in the number of sessions held, owing to the resignation of one dental officer and the illness of another. It is interesting to note that the number of children made dentally fit (8362) very nearly coincides with the number of school entrants (approximately 8400), which suggests that even with the present staff every child could be made dentally fit at some time in its school life. But following up and re-treatment make necessary an increase of staff which is to be provided in the coming year. A special investigation on orthodontics was made by Mr. M. Lewis, L.D.S., who found that nearly one-third of the children he examined had some irregularity of the teeth. In over half the cases the irregularity was associated with nasal obstruction. Irregularities of the teeth were found to be twice as common in breast-fed as in bottle-fed children. There is apparently a lack of day special schools belonging to the authority. A good number of totally blind and totally deaf children are maintained in suitable schools, but the lack of accommodation for mental

defectives and epileptics in the county is acute, and there is great difficulty in dealing with the cases of combined defect. Two interesting investigations were carried out. Dr. H. S. Bryan examined the general intelligence level of Peak District children, and showed that their average intelligence quotient, calculated on the Stanford Revision, was 99·4—that is to say, the scale is generally applicable to these children. Dr. F. J. Burke investigated lung diseases in school-children, and found that they are often associated with septic tonsils, adenoids, and other morbid conditions of the upper air passages.

Hull.

Dr. W. A. Daley has left Hull to take up a public health appointment in London after only a brief period of office, but the fruits of his organising capacity are to be found in the report to which his successor, Dr. W. M. Frazer, writes an introduction. In the 1927 report the need of myope classes, of an open-air school, of provision of X rays for ringworm, and of an increased dental staff was urged. Now a myope or sight-saving class has been provided whose only fault is that it is not yet large enough; there are open-air classes being held, and an adequate open-air school is under construction. Treatment of ringworm by X rays is working with success, and has just been made available for pre-school children; and this year the dental staff has been again strengthened by the appointment of two more dental officers and a dental attendant. Last year Dr. Daley described his scheme of dividing public health work into four sections: (1) tuberculosis; (2) maternity and child welfare; (3) school medical service; (4) port sanitation and infectious disease. All these services were to be coördinated so that the staff of any division could come to the help of another in case of need, and that the institutions and facilities belonging to each would be at the service of the others. This scheme has now been in operation for some time, and this year lists are given of cases referred from one division to another. Dr. J. Morrison, who is responsible for a large section of the report, writes appreciatively of the coöperation between the school medical department and the general public health department in matters affecting the control of infectious disease in school-children. The coöperation is especially close in relation to the pre-school child, the number of these infants treated at the clinic being over 1000 in addition to 12 cases treated by plaster splints at the Park Avenue Special School. In many other matters improvement is chronicled; a minor example is that of the restriction of casual dental cases. Previous reports gave the reasons for preferring systematic dental treatment and prophylaxis to "last moment" action. This year the number of casual cases has fallen to the very low figure of seven, and experience in 1929 again showed that the public appreciated the fairness of the policy. Only in one respect is this report disappointing. In the report for 1928 it was stated that an orthopædic hospital appeared to be in prospect; this year it is noted that very little progress has been made with the scheme. Special investigations include a scientific study of impetigo in school-children by Dr. Morrison, and an experimental study of the results of the use of tonic medicine in schools by Dr. K. D. Mackintosh.

Warrington.

Dr. G. W. N. Joseph thinks that the relatively low proportion of defects found in Warrington is accounted for partly by the work of the maternity and child welfare committee among pre-school children, and partly by the efforts of the nurses in the schools. A table shows that among the school entrants who had previously attended a welfare centre only 21·5 per cent. were found to have defects, while among the other children the percentage was 31·2. It is clear that much successful treatment is carried out in the schools by the nurses, who also visit the homes and give advice to the parents on home treatment. The system of doing dressings in the schools has caused a great reduction in the loss of attendance due to minor ailments. A special inquiry showed that loss of attendance due to infectious disease is another important factor, but not the principal influence, since in 1922–23, when 128,347 attendances were lost owing to an epidemic of measles and mumps, the percentage of attendances was 91·5, an exceptionally high figure. This year the total loss of attendances through minor ailments and infectious disease together was 100,000, while 200,000 attendances were lost through disease for which certificates from private doctors were produced by the parents, the amount of loss through this last cause having markedly increased since 1921. Dr. Joseph believes that there is here a fruitful field of inquiry which will be made in the course of this year. At Warrington no open-air school, nursery school, or special school of any kind exists, and at present no system for provision of meals is operating. In two schools an excellent plan for the giving of milk, made possible by the self-sacrifice of the teachers, is producing good results, but other schools have not found it possible to adopt the scheme owing to lack of staff.

Rutland.

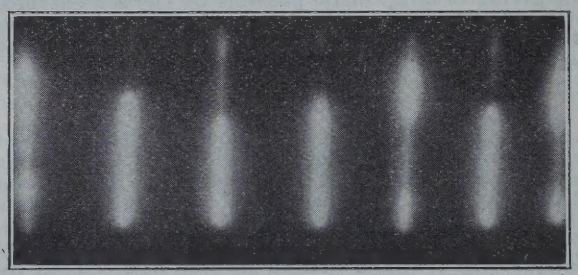
Dr. C. Rolleston, who is in charge of the smallest county in England, issues merely a brief typewritten report which does not reproduce the figures and statistical tables furnished to the Board of Education. In spite of the small numbers of children concerned, the facilities for treatment seem to be reasonably adequate in Rutland and to be well appreciated by the parents. The orthopædic scheme is much in favour; there was only one refusal of treatment. The operative treatment of tonsils and adenoids at the Oakham War Memorial Hospital is of high standard; 90 children have received attention by Dr. F. H. Wallace, but 121 still require treatment. The interest of the parents is illustrated by the large proportion (82 per cent.) attending the medical inspection of their children. This attitude is a great change from that of a few years ago, when the parents viewed the medical services provided with distrust and dislike. Even to-day, Dr. Rolleston says, a few exceptions remain. A mother refused to obtain treatment for her boy's vision, though it was only one third of normal; when she could hold out no longer against persuasion and pressure, including a warning from the N.S.P.C.C., glasses were obtained, but the mother then made a further stand. She realised she could be compelled to get treatment for her boy, but she protested that no law could compel her to force him to wear the glasses prescribed. Dental work has been hindered by a change of dentist, the post being left vacant through illness for two months last year. Improvement on the conservative lines suggested by the Board of Education has, however, begun, the number of permanent teeth extracted having fallen; there have also been many more fillings of temporary teeth, since the present dentist, Mr. L. A. McTaggart, does not favour the extraction of these teeth. The system of a travelling van is proving satisfactory, but the work needs acceleration. If the dentist cannot visit each school every year, children may be left without dental care for so long that some teeth may become unsaveable in the interval. The appointment of a skilled dental attendant or nurse would speed up the work, and it is clear that such an appointment should be made without delay. The duties of the school nurse include assisting in splint and plaster work at the Peterborough orthopædic clinic and giving lectures to elder girls on the hygiene of infancy. Several inquiries were made in the course of the routine work, notably about the proportion of children who had been breast fed, who were vaccinated, who had had symptoms of rheumatism, or who were working out of school hours. The numbers concerned are small, and no general conclusions could be drawn from them. Dr. Rolleston also carried out a special investigation of an acute epidemic at Morcott, which was presumably poliomyelitis with some special features.

CORRESPONDENCE

INEQUALITIES IN RADIUM TUBES.

To the Editor of THE LANCET.

SIR,—In this clinic we have read with great interest the article on Distribution of Radiation from Clinical Radium Tubes by Prof. S. Russ and Miss D. F. Clephan (THE LANCET, August 9th, p. 286). Our physicist, Mr. Hubert Lawrie, has been engaged in taking autophotographs of our needles during the last six months and we have been very perturbed on finding that the distribution, as shown in the photographs, is almost invariably uneven. The active material is usually found concentrated towards the



Autophotograph of seven radium needles with consecutive numbers, each containing 3 mg. element. The needles are 6 cm. long (5 cm. active length), 2·2 mm. external diameter, walls 0·6 mm. thick. Exposure 300 secs. The needle-points are directed upwards.

eye end and must obviously, as Prof. Russ says, militate against uniform irradiation since the action will be concentrated towards the surface in most interstitial applications.

The problem, therefore, that we are faced with is how to get this defective filling corrected. We have already tried tapping and shaking but without any effect so apparently the only solution is refilling. As there must be other clinics possessing similar unevenly filled needles it would be advantageous to all concerned to go into the matter on the lines suggested by Prof. Russ so that, if necessary, combined action could be taken to have defective filling remedied. The appended autophotograph of seven consecutively numbered needles confirms the statement made by Prof. Russ.—I am, Sir, yours faithfully,

JOHN H. WATSON, M.B., B.S., F.R.C.S.,
Director, Radium Clinic, Victoria Hospital,
August 14th, 1930. Burnley, Lancs.

COLOUR-VISION AND COLOUR-BLINDNESS.

To the Editor of THE LANCET.

SIR,—Colour-blindness seems to be occupying great attention at the present time. Two very important communications on the subject have appeared this year. The first a book by Prof. Henschen of Stockholm, on "Lichtsinn und Farbensinnzellen im Gehirn." Prof. Henschen claims that he has proved that there are distinct cells in the visual centre for the perception of light and colour, thus supporting my theory which he quotes.

The second is an article by Dr. William Christie, medical inspector of schools, which appeared in the *Medical Journal of Australia* for Feb. 22nd. Dr. Christie's remarks are based on the examination and re-examination of 20,000 school-children, and he used my classification, those examined being grouped according to the number of colours seen in the spectrum. He states, "One great advantage of Edridge-Green's system of classifying colour-blindness is that it enables us to foretell what colours will be selected to match another colour when once the spectrum of that boy has been obtained." Dr. Christie has made the surprising discovery that on re-examination there is a definite change in the degree of colour-blindness. About 25 per cent. of all persons improve. The same number get worse and the remainder are approximately stationary. Some improved to such an extent that Dr. Christie no longer regarded them as colour-blind.

I am, Sir, yours faithfully,
F. W. EDRIDGE-GREEN.

Board of Trade, August 14th, 1930.

TREATMENT OF PULMONARY TUBERCULOSIS IN SWITZERLAND.

To the Editor of THE LANCET.

SIR,—If the members of our profession will consider the reflections of Dr. Harrison carefully, these will influence the lives of a larger number of individuals in these islands than any other matter recently published in your journal. This statement may appear somewhat dogmatic but the widespread prevalence of tuberculosis gives it emphatic support. His article had a very special appeal to me because here, 1000 feet above sea-level, our winters are very severe, wet, and prolonged. We endure more than our fair share of snow, rain, and mountain mist, and reckon on a month more of actual winter weather than our neighbours at lower levels. We also suffer from lack of sunlight, and for many years I have seen, in the early months of the year, many fresh cases of pulmonary disease. Why should I send these unfortunates from this height to other heights in a colder land, far from their relatives and home interests? I admit this would reduce the number of "contacts" in this country.

Our practice has always been to send cases to our home sanatoria, our southern coast line and the Channel Islands, and our results have been most encouraging. It is a pleasure to see well-marked cases with pallor and tachycardia, irritating cough, and increased root shadow, whom we know to be contacts, return to us full of life and vigour. It is sad to watch the downward trend of cases unable to afford the two or three months treatment necessary. We have many excellent sanatoria, and it is unfortunate that they do not admit all early cases. At the same time we confess that the early cases are not very infective. Probably for those who can afford it residence on the high veldt of South Africa is the ideal treatment; but they should stay there. These cases relapse easily on return to this country.

I have just read Dr. Amrein's letter. It is remarkable how widespread his idea of our climate is on the continent. It is fortunate that our webbed toes and very sensitive touch corpuscles enable us to get about our business with such rapidity in this land of perpetual wet and gloom.

I am, Sir, yours faithfully,
R. S. MCCLELLAND.

Dowlais, South Wales, August 15th, 1930.

To the Editor of THE LANCET.

SIR,—I have read with interest the correspondence in your columns on this subject and I should like

take this opportunity to correct the impression ich Dr. Harrison's article may have made. My marks must be based on the only treatment centre Switzerland of which I have personal knowledge.

(1) *Situation.*—This centre has the great advantage being situated on a plateau and enjoys a superb w up and down the Rhone Valley, of which the e never tires. In contradistinction to the effect of nhappy constriction," to which Dr. Harrison refers writing of the Swiss landscape, a sense of open aces prevails. Facilities for walking are, I believe, tter than in any other Swiss resort; it is possible walk for an hour or so on the level in more than one rection. With regard to winter sports, Montana ice the war has ceased to count as a "sports centre" d has been given up almost entirely to the treatnt of tuberculosis.

(2) *Climate.*—No one would deny that the dry riss air is beneficial in cases of pulmonary tuberculis, nor the advantages of the increased appetite luced. Owing to its open position facing south, ntana receives the maximum amount of sunshine. e psychological effect of the sun cannot be overimated, and however strongly Dr. Harrison may ld a brief for our English climate the average nter day in England or Scotland affords little cheer the patient in bed and no encouragement to those shing to pursue "outdoor Nature study."

(3) *Sanatoria.*—Here lies the crux of the matter. is obvious from the letters in your columns and m my own observations that the administration many Swiss-run sanatoria is defective, especially th regard to nursing facilities, and that in some itances medical treatment differs considerably from at carried out in our own sanatoria. The al would seem to be a sanatorium in Switzerland uipped entirely by a British medical and nursing ff. Such a sanatorium is now nearing completion Montana.

I am, Sir, yours faithfully,

ndon, W., August 17th, 1930. DOUGLAS MCALPINE.

UMBILICAL HERNIA IN INFANTS.

To the Editor of THE LANCET.

SIR,—I think Dr. Eric Pritchard misses the point Mr. Wakeley's remarks on infant feeding. Wakeley does not say "artificially-fed infants"; t "infants brought up from birth on patent foods" a very different thing. A baby fed on properly uted cow's milk does not suffer from indigestion or nstipation, but an infant brought up on patent foods nost invariably does, and these, I gather, are the es to which Mr. Wakeley refers.

I am, Sir, yours faithfully,

J. HAMILTON HART.

Worcester Park, Surrey, August 15th, 1930.

FIRE PRECAUTIONS IN NURSING HOMES.

To the Editor of THE LANCET.

SIR,—More than half of my time during the past n years has been spent as a patient in nursing mes in London and seaside towns, so that I may im to be something of an authority on these instiions. I have already observed good results from e new system of registration and inspections. ere is one point, however, which well might receive e attention of authority—that is, the arrangements, lack of such, for removing those patients who are able to walk, in case of fire. In only two of half a dozen otherwise well-conducted establishments which I have lived in and others I have visited in choosing a place have I felt satisfied that there was any plan or understanding on which the staff would work in getting out patients after the start of a serious fire, particularly at night. It has been my experience that if a patient asks questions about the subject (particularly if he wants specific and detailed information) he is likely to get vague assurances that everything will be all right.

I have been a patient in three homes in which the control was entirely in the hands of a matron, and in two where there was no male member of the staff and no man on the premises at night, and where no apparatus for dealing with a sudden fire was visible. Only a small proportion of the nursing homes I know were built for their purpose. Most of them were originally dwelling houses and have been more or less remodelled for their present use. One of the best (in other respects) London homes I have been in as patient was a tall narrow house with very narrow halls and stairways. Getting a patient who must be carried out of doors from the third or fourth floor, as I know by experience, was a very slow and clumsy proceeding. What would happen if it became necessary to get several out quickly? The choice of a nursing home is made by most people on the recommendation of their doctors. Whether the average doctor feels that responsibility rests upon him to make sure that the place he proposes is efficiently organised in regard to such matters as are outside of his professional sphere I cannot say.

It seems to me that the establishment of regulations or standards regarding fire precautions and insistence that they are observed would be a most desirable reform. It is one that should be dealt with in advance rather than as the result of a coroner's inquest.

I am, Sir, your faithfully,

August 16th, 1930. PATIENT.

DRAINS.

To the Editor of THE LANCET.

SIR,—The leading article in your last issue on drains might lead one to suppose that drainage was of no importance as a cause of epidemic diseases. Are we to believe that a reversion to the state of affairs that existed in this country a hundred years ago would not be associated with a recurrence of the epidemics which, as you point out, were probably brought under control by the attention subsequently paid to all forms of sanitation, including drainage? In the *Times* of July 25th it was reported that typhoid is occurring in such volume at Leningrad at the present time as to cause serious concern, and the impression is conveyed that part of the cause may be the primitive system of cleansing and sanitation generally in that city. Scepticism, no doubt well justified, as to the connexion between drains and many of the infections should not lead us to discount the very great importance of sanitation, including drainage, in the prevention of at least some of them.

I am, Sir, yours faithfully,

August 18th, 1930. M.B.

*** We agree with "M.B.'s" general argument. We were careful to emphasise that there was a genuine case for the urge toward drainage and sewage disposal in the second quarter of last century, and that adequate drainage arrangements must be maintained on general principles. The important point, however, is to secure differentiation both in the medical and lay mind between those diseases which may be

attributable to faults of drainage and those which may not. Briefly, it may be said that a community which allows its water-supply to become contaminated by its drains, or permits flies to have access to its sewage in the crude state by failing to provide drains, is taking the risk of epidemics of the alimentary infections, such as typhoid, dysentery, cholera, and infantile diarrhœa; but that the diseases which are conveye mostly through the air by droplet infection, such diphtheria, scarlet fever, measles, influenza, and so o are not likely to be affected one way or the othe Historically there is no evidence that these latter ha diminished in incidence during the era of mode sanitation.—ED. L.

OBITUARY

JOHN ELDER MACILWAINE, B.Sc. Glasg., M.D. R.U.I., D.P.H.

THE sudden death on August 6th of Prof. J. E. MacIlwaine, at the comparatively early age of 56 years, has deprived the Belfast Medical School of one of its most distinguished and most scientific physicians.

John Elder MacIlwaine was born in Belfast in 1874, the son of John H. MacIlwaine, a well-known naval architect and engineer, and one of the pioneers of Belfast shipbuilding. It was natural that after his education at the Royal Academical Institution, Belfast, he should first of all enter his father's shipyard, and there serve his apprenticeship. He then went to Glasgow, where he took a University degree in naval architecture, but after his return to Belfast he abandoned this career for medicine. He had a brilliant career at Queen's University, then Queen's College, Belfast, where he was uniformly first in his examinations. Tall and strong, with a good turn of speed, he distinguished himself equally on the football field, and as a forward he had the honour of representing Ireland during three years in her palmy days of the nineties. A popular student, he took his part in the college life, his unusually sweet and vibrant voice being appreciated by his fellow students. While studying in Dublin during his final year the South African war broke out, and he promptly joined the Irish Hospital as a dresser. His work in South Africa was mostly medical, and he always spoke in the highest terms of his chief, the late Dr. J. B. Coleman, of Dublin.

On his return home MacIlwaine took the M.B. degree of the Royal University of Ireland with first-class honours, and then went to the continent for a prolonged period of study—Berlin, Vienna, where he spent almost a year, and then Paris. He then came home and served for a year as resident in the Royal Victoria Hospital, Belfast. After he had set up in practice he was connected with the hospital, first as medical registrar and medical tutor, and in 1911, on the death of Dr. W. B. McQuitty, he became assistant physician. He was always interested in diseases of the heart, and it was after seeing the work of Sir James Mackenzie at the London Hospital that he established an electrocardiographic department at Belfast in 1913 for which his early training in mechanics and engineering had so well fitted him. Having served many years as full physician to the Victoria Hospital, in 1929 he was appointed to a specially created post of physician in charge of the cardiographic department. During the great war he joined the staff of the St. John Ambulance Brigade Hospital at Étaples, taking out his own cardiograph with him, and his work done there on D.A.H. cases soon drew the attention of the medical authorities to its value.

After the war the chair of materia medica and therapeutics at Queen's University becoming vacant on the resignation of Sir William Whitla, Dr. MacIlwaine was elected and filled the post until 192 How much labour he expended on the preparati of his lectures and their revision year after year a what the strain of teaching a subject alien to h personal interests is known only to his intimate friend Gradually he restricted his consulting practice cardiac work, and he was one of the founders of t Cardiac Club in connexion with the Association Physicians of Great Britain and Ireland. His medic colleagues recognised his worth by electing hi President of the Ulster Medical Society and Preside of the North of Ireland Branch of the British Medic Association.

About five years ago Dr. MacIlwaine lost the sig of one eye from detachment of the retina and h general health began to fail. He resigned the cha in 1928 but not before he had persuaded the medic faculty of the University to adopt his schem laboriously and carefully worked out, for converti his chair into one of pharmacology with a train full-time professor of pharmacology at its head. H lived to see that department grow and develop und Prof. E. B. C. Mayrs, new laboratories furnished, and connexion established with the Royal Victo Hospital. In October, 1929, symptoms pointing detachment of the retina in his sound eye appeare A visit to Switzerland for the most recent treatme resulted in disappointment, and he bravely fac blindness and the whole readjustment of his li For some months before his death he was studyi the Braille system and hoped to be able to adapt to the reading of his large collection of electro-card grams, and thus pass some of his enforced leisure giving of his wide experience to medical literature.

A colleague, on whose knowledge we have alrea largely drawn, writes: "MacIlwaine excelled as clinical teacher, and drew a large crowd of students w were attracted by his lucidity and the practical natu of his bedside teaching. He keenly enjoyed lecturing his own speciality, and his early training in engineeri enabled him to draw many illustrations fr mechanics which helped the student in his und standing of the heart and circulation. He alwa urged the great necessity of ordinary methods clinical observation before making use of instrumen ones. In one of his last conversations with the wri he voiced the fear that the public were beginni to place an undue importance on the electrocard graph, and hoped that medical men would not all themselves to be forced to use it in cases of card disease where its employment was quite unnecessa His friends regretted that he did not write more his special subject, but his modesty made him hyp critical of the importance of his own work, and the fruit of his wide experience and patient investi tion is left ungathered. He inspired valuable resea in his wards and was ever anxious to assist in ev way the younger medical man. His life and wo quiet and unobtrusive, conscientious and thorou was an example to every medical student of what best in the art of medicine."

CHARLES BROOK, J.P., F.R.C.S. Eng.,
LIEUT.-COL., R.A.M.C. (T.).

Mr. Charles Brook, who died at Lincoln on ugust 10th, was a son of the late Dr. W. H. Brook, Lincoln, where he was born on Feb. 19th, 1839. fter a year's pupillage at the Lincoln County ospital he entered St. Bartholomew's Hospital, ondon, in October, 1858, the same year as Alfred illett, John Langton Morrent Baker, and Howard arsh, the first three of whom were his fellow house rgeons, whilst the latter, after the custom of that me, purchased the remainder of the house surgeoncy Mr. Skey, which Charles Brook resigned owing to e illness of his father, calling him to Lincoln. uring his student days he gained every scholarship d prize that he competed for; Sir James Paget ied to persuade him to remain in London as his sistant, and the treasurer and almoners added their surance of an early post on the surgical staff if he ould so remain. But Brook felt it his duty to carry his father's practice in Lincoln, which he joined 1862.

He was elected surgeon to the Lincoln County ospital in 1864, consulting surgeon in 1900, and vice-esident in 1921. In 1862 he was appointed surgeon the Royal North Lincoln Militia, from which he signed in 1891, but on the formation of the Territorial orce in 1908, at the request of Sir Alfred Keogh he ganised the Fourth Northern General Hospital. Here, uring the war, he took the principal surgical part om 1914 to 1918, when, whilst still active in mind d body, he was retired, at the age of 79, by reason the age-limit. In 1922 the Royal College of rgeons elected him a Fellow. A fine operator in his rlier days, Mr. Brook was during the whole of his reer distinguished for his clinical acumen, power of agnosis, and shrewdness in treatment, so that his lvice was sought after over a wide area. He was a ne sportman, a cricketer from his earliest days, keen follower of hounds, a fine shot, and able to amp over the heather until approaching 80 years age. He was chairman of the Lincoln Race Com-ittee, and at one time raced under the name of r. Seabrooke.

A man of sound business ability, Colonel Brook was n the boards of some of the principal business ncerns in Lincoln, being chairman of the Lincoln d Lindsey Bank (now merged in the Midland) d of the Midland Counties Insurance Company ow merged in the Royal). He was made a J.P. 1888. He leaves a son and a daughter, his wife d an elder son having pre-deceased him.

PROF. AXENFELD.

Dr. Theodor Axenfeld, who died at the age of 3 years at Freiburg i. Br. on July 29th, had held ie University chair of ophthalmology for almost) years. He was born at Smyrna, graduated at arburg, and was assistant to Uhthoff at Breslau efore his appointment at the age of 30 to the chair ophthalmology at Rostock, which he exchanged r that of Freiburg four years later. Axenfeld's name associated the world over with the pathology of phthalmic disease, and especially with that of spring tarrh, trachoma, and sympathetic ophthalmia. His *ehrbuch der Augenheilkunde* ran through seven litions and from 1904 on he edited the *Klinische Monatsblätter für Augenheilkunde*. His international anding made it possible for him to resume his place in 929 at the Amsterdam congress, and early this year e had made a tour in Japan where he was received with marked respect. Three of his pupils occupy the chairs of ophthalmology at Cologne, Münster, and Tübingen.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdr. B. S. Robson is placed on the Retd. List with the rank of Surg. Capt.

Surg. Lt. D. M. Beaton to be Surg. Lt.-Comdr.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Sub-Lt. J. F. Corr to be Surg. Lt.

ROYAL ARMY MEDICAL CORPS.

Capts. E. J. S. Bonnett and F. K. Escritt to be Majs. (prov.).

TERRITORIAL ARMY.

Maj. T. W. S. Hills, having attained the age limit, retires and retains his rank, with permission to wear the prescribed uniform.

Capt. A. B. Williamson to be Capt.

2nd Lt. J. K. Reid to be Lt.

Godfrey Morgan to be Lt.

ROYAL AIR FORCE.

J. F. S. Wiseman is granted a short service commission as a Flying Officer for three years on the Active List.

Squadron Leader T. K. Place (Major, Army Dental Corps) relinquishes his temporary commission on ceasing to be employed with the R.A.F.

RESERVE OF AIR FORCE OFFICERS.

Flight Lt. J. Prendergast relinquishes his commission on completion of service.

INDIAN MEDICAL SERVICE.

Capt. T. H. Thomas to be Maj.

Capt. (prov.) K. F. Alford is confirmed in his rank.

Col. L. J. M. Deas retires.

Lt. H. S. Bawa relinquishes his temp. commn.

DEATHS IN THE SERVICES.

Colonel John Southey Bostock, R.A.M.C., C.B.E., who died suddenly at Burford Priory, Oxford, on August 12th, aged 55, was Commandant of the Royal Army Medical College at Millbank. The eldest son of Dr. E. I. Bostock, of Horsham, Sussex, he received his early education at Lancing College, and graduated in medicine and surgery at Edinburgh in 1900. In the following year he joined the Royal Army Medical Corps as lieutenant, became captain in 1904, and major in 1912. He served throughout the great war both at home and abroad, and was in the retreat at Mons. On his return to England he took charge of the War Hospital at Eastbourne, and was director of medical services at the Ministry of Pensions from 1919 to 1923, when he was made C.B.E., and became Lieut.-Colonel, having been promoted to Brevet Major in 1915 and Brevet Colonel in 1918. Subsequently he was appointed principal medical officer at Hong-Kong, and in the early part of this year took up his appointment as Commandant at Millbank. He married in 1909 Olivia Emslie, daughter of Mr. Emslie J. Horniman, by whom he had two sons and one daughter.

CITY OF LONDON MATERNITY HOSPITAL.—The 179th annual report records that last year 1724 in-patients were treated at a cost of £7 17*s.* 6*d.* each for an average stay of 13·45 days, a reduction of 12*s.* 5*d.* on the preceding year. Of the in-patients seven died, two of whom were emergency cases; the mortality-rate for booked cases was 3·22 per 1000. There were 37 pairs of twins, and 72 stillborn cases. There were 251 out-patients delivered, and 256 children were born outside the hospital. In ante-natal and postnatal work 2070 patients were attended. In the infant welfare centre 431 mothers made 4629 attendances. Nineteen medical practitioners and students attended the practice in the hospital, and 40 midwives and six maternity nurses were in training during the year. The report emphasises the extreme urgency of rebuilding the nurses' quarters—the present lack of accommodation threatens the efficiency of the hospital.

MEDICAL NEWS

Mental Treatment Act, 1930: Approved Medical Practitioners.

The Board of Control, with the approval of the Minister of Health, have appointed a committee "to consider and advise what principles should be observed in the approval by the Board of Control of medical practitioners for the purposes of Sections 1 (3) and 5 (3) of the Mental Treatment Act." The committee is constituted as follows:—Sir John Rose Bradford (President of the Royal College of Physicians), who will act as chairman; Sir Hubert Bond (Commissioner of the Board of Control), Dr. R. G. Gordon (representing the B.M.A.), Dr. G. W. B. James (Royal Society of Medicine), Dr. A. Rotherham (Commissioner of the Board of Control), Prof. J. S. B. Stopford (General Medical Council), Dr. R. Worth (Royal Medico-Psychological Association), with Mr. H. C. Bleakley, of the Board of Control, as secretary. Under Section 1 (3) of the Act the application of the parents or guardian of any person under 16 for his admission to an institution for mental treatment as a voluntary patient must be accompanied by a recommendation from the usual medical attendant, or from a medical practitioner who has been approved for the purpose of making such a recommendation. Section 5 (3) refers to the medical recommendation which must accompany the application of relatives of a patient who is for the time being incapable of expressing himself as willing or unwilling to receive treatment for mental illness, but is likely to benefit by temporary treatment. This recommendation must be signed by two registered medical practitioners, of whom one must be approved by the Board of Control for the purpose of making recommendations under this section.

St. Thomas's Hospital.

The old students' dinner will take place at St. Thomas's House, Lambeth Palace-road, London S.E., on Oct. 3rd, at 7.30 for 8 P.M. The chair will be taken by Dr. R. Muzio Williams.

The following scholarships have been awarded for 1930. University Scholarship: H. F. Moseley, Merton College, Oxford. Hector Mackenzie Exhibition: I. H. Gosset, Magdalen College, Oxford. Entrance Scholarship in Arts: R. R. McSwiney and A. J. Belsey. Entrance Scholarships in Science: First, G. W. Hearn; second, W. E. Hadden and J. I. Lesh. William Tite Scholarship: L. E. Jones.

Chartered Society of Massage and Medical Gymnastics.

The second annual dinner of this society will be held at the Midland Hotel, Manchester, on Friday, Oct. 3rd, at 7.30 P.M.

Medical Society of Individual Psychology.

This society, which aims at bringing together those who are particularly interested in the medical aspects, both theoretical and practical, of individual psychology, will in future meet at the rooms of the Medical Society of London, Chandos-street, W.

Modern Churchmen's Conference.

Among the papers read at this conference, which was held this week at Oxford, the Dean of St. Paul's presiding, were Principles of Sexual Conduct, by Dr. Douglas White; the Influence of Birth Control on Individual and Racial Health, by Mr. C. J. Bond, F.R.C.S., and Eugenics and Population, by Prof. F. A. E. Crew.

People's League of Health.

The 1930 Travelling Scholarship in connexion with the annual series of Sims Woodhead Memorial Educational Health Lectures given by the People's League of Health was won by Mr. A. Hounslow, a first-year medical student of University College, London. Mr. Hounslow will visit the Pasteur Institute in Paris and Dr. Rollier's clinics at Leysin.

Paddington Medical Society.

At the usual monthly meeting, held in the Great Western Hotel on August 12th, the President, Dr. De Swietochowski being in the chair, an address was delivered by Dr. A. Welply, secretary of the Medical Practitioners' Union, entitled "Past, Present, and Future of Medical Practice," in which he described the changes which had taken place within the last 20 years and the various factors which affect the work and position of the practitioner to-day.

University College Hospital.

Last year this hospital treated 8374 in-patients, whos average stay was 21 days; they cost £10 9*s.* 7*d.* eacl There were 77,129 new out-patients whose cost was 5*s.* 4*d* per head. The income—£113,929—exceeded expenditur by more than £10,000.

Manchester Royal Infirmary Old Residents' Club.

The triennial dinner will be held on Oct. 25th. An former residents who have not received notices are aske to communicate with the secretary of the club at the Roya Infirmary, Manchester.

Hospitals as Companies.

The Liverpool Hospital for Consumption and Disease of the Chest has been registered as a company limited b guarantee. The Royal South London Ophthalmic Hospit has been similarly registered.

High Wycombe War Memorial Hospital.

This hospital is to be enlarged by the addition of 23 bed bringing up the total number to 55, and a children's wa is to be provided.

St. Mark's Hospital.

The annual report of St. Mark's Hospital for Cance Fistula, and Kindred Diseases, City-road, states that la year there were 806 in-patients and 1804 new out-patient Miss Florence Clarke gave £1200 for radium, of whic excellent use has been made, and the results of the trea ment are receiving intensive study.

Enlargement of Croydon Hospital.

Two wards are to be extended to accommodate 44 add tional beds, and provision is also to be made for 17 "pa beds." Three houses at the rear of the hospital are to reconstructed as the Charles Heath Clark Memorial Nurse Home with a grant from Mr. Clark's executors.

Torbay Hospital Chapel.

A memorial chapel, which has been added to th hospital at the cost of Mrs. Rowcroft, was dedicated la week by the Bishop of Exeter.

Sidmouth Cottage Hospital.

Last week the foundations of an extension of this hospit were laid by Mrs. Balfour, wife of Colonel Balfour, who ga the site of the present building. The population of Si mouth has doubled since the hospital was enlarged in 191 and the number of beds is now being increased from 14 to at a cost of £14,000.

Carlisle as a Medical Centre.

Lord Howard of Penrith recently opened two new war of the Cumberland Infirmary at Carlisle. The Balfo Paul Ward, which commemorates the late Mr. C. Balfo Paul, hon. surgeon to the infirmary, and cost £4600, w given by members of his family; the Woodside War which cost £5000, is the gift of Mr. Andrew Gibson. The additions, with a pathological department, nearly comple an extension scheme costing £55,000, the whole of whi has been provided. In a speech at the opening ceremo Dr. Norman Maclaren said that although money w difficult to get, he hoped that the Cumberland Infirma would presently be able to form a training centre. T hospital already has a successful nursing school, and had met nurses trained there in India and on the Weste front. He hoped they would have a school to whi medical men in the district, and probably from beyond would go to see the work done in the infirmary.

Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

NOTES, COMMENTS, AND ABSTRACTS

PREVENTIVE MEDICAL EXAMINATIONS IN INDUSTRY

AND ORGANISED MEDICAL PRACTICE.

By Dr. René Sand,

TECHNICAL COUNSELLOR OF THE LEAGUE OF RED CROSS SOCIETIES (PARIS).

PREVENTIVE medical examinations were introduced first in the army and navy, to be extended later to various schools and to the colonial civil service. Twenty or thirty years ago, however, many industrial and business concerns had already a medical service intended mainly for the emergency treatment of accidents. The popular campaign against tuberculosis roused some employers to a realisation of the danger of contagion in offices or workshops. They asked their medical service to investigate the matter; to their great surprise, numerous cases of open tuberculosis were detected in their staffs. Evidently, the only remedy for this situation was to submit every applicant for a job to a routine medical examination. This practice was found to have other advantages: it did away with the hiring of people physically incapable of working regularly; it enabled the management to assign every one to a job for which he was fit; it prevented representing old-standing disabilities—a hernia, for instance—as the result of an industrial accident, for which compensation was claimed; it gave the examining physician an opportunity to extend valuable health advice to applicants.

USES OF THE PREVENTIVE EXAMINATION.

As a rule, the results of these preventive medical examinations proved excellent; the labour turnover, the removal from one job to another, the time lost for sickness, the accidents, the wastage of goods, all diminished in a striking proportion. It became evident that preventive medical examinations save money to the employer, and that a good medical service is one of the elements of industrial efficiency. At the same time, these examinations helped the employee in preventing him from wasting his health in a job to which he was physically unequal, and in giving him an opportunity for treatment of existing handicaps.

In order to be really useful to the applicant, these examinations must be thorough; they call for the help of specialists, of X rays, of laboratory procedures. In this form they are becoming popular among all classes in the United States, where the Life Extension Institute, a non-profit yet self-supporting institution, has already made more than a million preventive examinations. Life insurance companies offer these examinations free to their policy-holders. Those who take these examinations show such diminished death-rates that the insurance companies gain two dollars for every dollar they pay to the Life Extension Institute, thus making a net profit equal to the expense they have incurred. Here we have the material proof that preventive medical examinations pay in supplementary years of life, health, and efficiency much more than they cost.

However, a man who has been found fit at a first examination may later fail in health. This led some firms to introduce an annual medical examination of their staff. We have thus three degrees in the health supervision of the employees: the summary medical examination, the thorough medical examination, and the annual or periodical examination. Of course, the first is the most usual, as it takes less time and is less expensive. With a good medical organisation it can be done in ten minutes, and is said to cost between one and two dollars in the United States. A thorough medical examination tal half an hour, and costs between 10 and 20 dollars.

DOUBTS AND FEARS.

Some workmen have feared that these examinatic would be used as a pretext to eliminate trade-uni leaders or people known for their radical opinio I am told that this has actually happened; it mu however, remain very exceptional. One har imagines that a manager who is farsighted enou to spend a considerable sum of money in medi examinations of his staff should use them in a w which must lead rapidly to their discredit. Anotl more serious objection is that this procedure mal life very hard for the handicapped, and practica throws them on public or private relief. These peo surely deserve our consideration. But, first of the examination is not conducted with the idea f eliminating everyone who is not in the best of healt it is merely made the basis of a job-selection wh enables an employer to accept many of the han capped. Those who are rejected are either contagi cases or people who could not undertake any regu work; if accepted, they would soon exhaust th remaining strength or incur accidents. Indus is not responsible for this situation, and the rem is not to hire for a few days or a few weeks a m who will soon have to give up work, but rather provide for him through an insurance scheme.

PREVALENCE OF ILL-HEALTH.

These examinations, whether made in indust circles or among the general population, bring light the rather sad fact that almost no one is complet healthy. Less than half of the people who beli themselves fit enjoy normal weight and nor posture. Less than half have normal eyesight. L than half have a normal throat and nose. Less th half have normal teeth. Forty per cent. suffer fr constipation. Luckily, 80 per cent. have a sou heart, good ventilated lungs, permeable kidne These statistics show that preventive medical exami tions have a twofold use; in a certain number of ca they lead to the discovery of unsuspected and seri troubles which can then be adequately treated; the majority of cases they reveal minor trou which, while they do not imperil the life of the subj nevertheless diminish his vitality and reduce efficiency. The correction of these troubles p the subject in a state of well-being from which he h been disaccustomed for years. Experience pro that one year after the first preventive examinat three out of ten defects are corrected; a sec medical examination leads to the correction of th further defects. This is interesting from individual's point of view, but even more so fr the point of view of the community. Mr. Ho Folks and others have reckoned that disease co the American nation 15 per cent. of its yearly inco It is admitted, however, that at least one-third the diseases prevalent to-day are preventable. T national income could thus be increased by 5 cent.

PREVENTIVE MEDICINE FOR ALL.

At this point one will inevitably ask: if th examinations are so valuable, why should they the privilege of clerks and workers in a limited num of concerns? Why does not every practitio examine in this way each member of the fami which call him when sick?

The reason is that medical practice has not adjusted itself to the progress of our knowledge. long ago medicine was more an art than a scien Contact with patients developed in the docto clinical sense which was almost his only resou His therapy was limited and often perfunct Seeing patients belonging to various walks of he could not trace the social elements which are

ep causes of disease; at any rate, he could not fluence them. Hygiene and preventive medicine ere still in their infancy. All that is changed to-day; edicine becomes more and more of a science, calling r complicated equipment, for laboratory procedures, d for the help of various specialists. The social orkers inform the doctor about the social causes diseases and try to remove these causes. The vance of hygiene and preventive medicine puts the hands of the physician effective weapons to otect and develop the health of the people.

But the practice of a profession cannot be transrmed easily or quickly. To change one's methods, to apt oneself to a new machinery, to create these new ethods and this new machinery, necessitates a huge ort and represents a serious risk. No profession as ever more individualistic than the medical profesn. Since its origin patient and doctor have been ne face to face. And now circumstances compel actitioners to work in teams; in the mutual benefit cieties, in health insurance practice, in the industrial edical services, in the school medical services, the child welfare services, in the tuberculosis, nereal disease, and mental hygiene dispensaries, ey have to accept new formulas, to do collective rk, to make themselves responsible to non-medical thorities; they have to coöperate with nurses and cial workers; they have, in the homes themselves, t only to cure but to prevent.

ISOLATED VERSUS ORGANISED PRACTICE.

Which profession has ever undergone a greater nsformation? Yet it is inevitable. Not that e family doctor is to disappear; on the contrary. ere exists no greater asset for the patient. The nflict lies between the *isolated* and the *organised* actice of medicine and it is the repetition, in another ld, of the conflict between artisan and big industry, tween the small shop and the great store. There ll remain isolated practitioners, just as there remain tisans and small shops. But organised practice ll take on increasing importance, it will attract e better elements of the profession, because it more efficient, more interesting, more scientific. d it is not less dignified or less lucrative. Some ysicians fear for their independence; is the isolated actitioner really independent? He has not one ster, he has a thousand. He will have to write ords, statistics, reports. Is it possible to treat atient efficiently without a record? Is it possible to mpare therapeutic procedures without statistics? alth accounts need figures and books just as bank counts. And if the doctor does his work conscienusly why should he fear inspection?

This organised practice is the kind of medicine ny of us have known in the war hospitals, and we en regret that in our isolation we are deprived the facilities we enjoyed for the treatment of the diers. It is also the best means to avoid the faults ich have been ascribed to insurance schemes. e would not hear of a "diagnosis and a prescription a minute" if the doctors worked in teams.

As regards the economic situation of the profession, m which many complain, raising our fees is not e solution. Let us see things as a whole; the tion pays each year a certain sum to the medical ofession, from private purses, from insurance funds, m public funds. To raise this sum we have to do the business man who wants to increase his sales. e does not raise the price of his wares. He tries reduce his overhead expenses, to improve his oduction, to turn out better commodities, to spread eir use; in a word, to serve the public better and to ch more people. It is exactly what the medical ofession ought to do. If the practitioners worked teams they would reduce their overhead expenses rent, heating, light, equipment, service; they would prove their work—think of all these tuberculous, acerous, arterio-sclerotic people whose illness is gnosed too late and treated with antiquated thods; think of this huge preventive work ich ought to preserve much more completely than is done to-day the pregnant women, the babies, the pre-school children, the school-children, the apprentices, and the adults. There is the "better commodity" which we ought to "sell" to the public. We can be sure that he will want it and be ready to pay for it. Then we will not hear any more complaints about "medical plethora"; if each man, woman, or child in England, for instance, underwent a yearly preventive medical examination and paid for it one pound—public authorities stepping in for those who are unable to spend this sum for their health—that would mean, divided equally, an income of nearly £1000 for every practitioner.

Of course, there is a long way to go before we reach that state, but is it not evident that preventive medicine is still too much neglected by our profession to our detriment, as well as to the detriment of the population? Preventive medicine necessitates teamwork, and cannot develop as long as we shut ourselves up in isolated practice. Thus the dilemma is: to stagnate in the present unsatisfactory condition, or to take a bold step forward and adopt an organised practice, which will be more efficient for the nation and more satisfactory, intellectually and materially for our profession.

THE SOCIAL SERVICE DEPARTMENT OF ST. THOMAS'S HOSPITAL.

THE work of the Social Service Department of the voluntary hospitals continues to increase year by year. It may seem a paradox, but the more State activities develop the more the voluntary hospitals are called upon to do. The annual report of the Social Service Department of St. Thomas's Hospital for 1929 gives a page of figures which, it needs little imagination to realise, must mean many and varied pressing needs. During the year 1537 patients were "convalesced" and of these 155 went to "free" beds and the rest to paying homes at a cost of over £4000, a figure which represents a decrease of cost but an increase of cases for the year. Incidentally, the report states that London has within a radius of a few hundred miles a better supply of convalescent homes than any other place in the world, and yet more homes for children, especially for medical cases, are needed. Children living under bad hygienic conditions respond more quickly to the surroundings of a convalescent home than any other type of case. The number of cases for whom home visits were paid by the Social Service workers of the hospital reached last year the total of 6417, of which more than half were in respect of out-patients and casualty cases. Accounts are given of 15 different departments of the hospital's activities ranging from new and rapidly growing departments, such as the mental department, where the early cases give much scope for social work, to the tuberculosis department where the State services have come to play such a large part, and yet still leave room for much voluntary effort. With the number of unemployed growing at an alarming rate social service work is full of difficulties these days. What effect the new Local Government Act and the public assistance committees will have on this side of the voluntary hospitals' work nobody can yet tell, but there is every reason to believe that the almoner's work will be increased rather than diminished.

A NEW WRAPPER FOR MEDICINE BOTTLES.

Messrs. H. Young, Myers and Co., of Astor House, Aldwych, London, W.C., have sent us samples of a neat container for medicine bottles. It consists of a paper bag so constructed that it lies flat while being addressed and readily expands when the bottle is being inserted. The bags are made in sizes to suit standard bottles of 6, 8, or 12 oz., and are much more convenient than the envelope or sheet of paper ordinarily used. They are firm, neatly finished, and inexpensive.

CLOTHING FOR WOMEN IN THE TROPICS.

FIRMS employing workers in the tropics usually provide a schedule of suitable equipment for the men who are going there, but the women are usually forgotten and have to rely on private advice. Even experienced tropical outfitters are rarely prepared with lists for women who propose to spend more than a brief time in the tropics. They are, therefore, apt to follow English summer fashions and to find that they are very inadequately fitted out. Dr. J. B. Christopherson [1] holds that feminine dress reform is an urgent need, for in his view the reasons why women do not survive tropical life are: the lack of preliminary medical examination, the lack of any useful occupation, and the unsuitable clothes worn by them. Dr. Christopherson urges women to wear exactly the same clothes as men: trousers, Jodhpurs, or plus-fours, with puttees, together with a tunic or smock. The evening dress suitable for this country is an invitation to the mosquito, and should always be supplemented by mosquito boots reaching above the knee, or by cashmere stockings under the silk, and the arms and neck should be protected. In the matter of underclothing women going to the tropics should seek the advice of expert outfitters used to supplying men. Wool, cashmere, silk, artificial silk, cotton, lawn, cellular material, mercerised cotton, and linen all have their place, but the wearer should be guided in their use in different areas and on different occasions by those with experience of the climate and entomological conditions of the district. Colour, texture, fabric, and style must all vary with varying conditions, and there is still room for research into the attraction of certain colours for certain insects; the relation of colours to light and heat and of fabrics to absorption, reflection and the conduction of heat and moisture.

NEW PREPARATIONS.

DRY OINTMENTS.—The selection of a suitable base for the incorporation of an active remedial drug is of great importance in the treatment of skin diseases, and does not always receive the consideration it deserves. Thus one frequently sees acute septic conditions treated with ointments, and lotions applied to a dermatosis resulting from an inherent lack of secretion from the sebaceous glands (xerodermia). The claims put forward by the manufacturers of HEKOTEKT (sole concessionaires: E. L. Fry and Co., 3, Pancras-lane, E.C. 4), a base compounded largely from "condensed skimmed milk," cannot, however, be accepted in their entirety. The casein constituent is not a new departure and has been embodied in many proprietary creams in this and other countries for years. Nor can it take the place of lotions in many of the more acute and weeping varieties of dermatitis, for a cooling and sedative effect cannot be obtained otherwise than by lotions. Hekotekt dry ointments deserve praise for convenience in application, for homogeneity, and for cleanliness; but the scope of their indications in skilled hands falls considerably short of those put forward by the manufacturers, while the combinations with drugs—such as sulphur, tar, zinc, resorcin, and chrysarobin—have the grave disadvantage of fixed percentages, which cannot be altered or modified to suit the individual patient. The preparations, while doubtless of value in selected cases, should not be used haphazard or without due consideration of the particular needs of any case in which their employment is contemplated.

COLACTIN.—The proprietors of Colactin (E. H. Spicer and Co., Ltd., Watford, Herts) state, as the main argument for its preparation, that milk sugar administered by the mouth rarely reaches the colon, and is therefore of so much the less value in modifying the intestinal flora. This preparation, cacao-oleum-lactin, is an effective suspension of lactose in mineral oil; it is lubricant of the intestinal wall and the emulsion protects the lactose (40 per cent. by weight) from digestion in the small intestine. There is medical evidence that persons with widely differing symptoms of alimentary toxæmia have benefited by the use of this simple remedy. The suggested dosage for adults is from half to one tablespoonful without addition of liquid before breakfast and upon retiring, while one or two teaspoonfuls make a sufficient dose for children. The proprietors call attention to the particularly good results that have followed certain cases where the taking of their B. Acidophilus Emulsion has been combined with the exhibition of Colactin.

NURSING IN THE U.S.A.[1]

PERUSAL of a small volume recently issued in America conveys the impression that nursing in the United States is in some directions a more fortunate calling than it appears to be in this country just now, for it would seem that the money-making possibilities of nursing have been advertised in America to an extent under which the avocation has suffered, inasmuch as when the question of earning a living has confronted an increasing number of girls the lucrative opportunities of nursing have proved persuasive to the wrong kind of entrants. There is no temptation of this sort for nurses on our side of the Atlantic, a point which does not need emphasising. It appears also that nurses in America are subjected to the kind of public flattery which, if the pages of mid-Victorian novels can be trusted, fell formerly to the lot of nurses in this country—namely, that they were called by the public "angels of mercy." This attitude towards nurses Miss Gladwin shows to be extremely distasteful to her, as well as to represent a complete misapprehension of values. She lays stress on the necessity for gentleness, kindness, and intelligent sympathy, but these qualifications must fall clearly into line with such other qualities as power of observation, respect for discipline, and the exhibition of good manners if the true efficiency of service is to be obtained.

Those who read this wise little book should remember that it is addressed not to the public but to an audience of young women adequately, but not—at any rate, generally—in the least highly educated, so that certain passages or whole essays in which the obvious appears to be unduly stressed must not be regarded as exercises in claptrap; they represent sound teaching, but in simple words for the benefit of those who may never have had formal instruction upon the fundamental tenets of social behaviour.

[1] Ethics Talks to Nurses. By Mary E. Gladwin. London: W. B. Saunders Company. 1930. Pp. 281. 8s. 6d.

A. W. F.—With reference to the depreciation of doctors' motor-cars from the point of view of income-tax, in 1925 the Government extended the wear-and-tear allowance on motor vehicles to members of the medical profession; whilst 20 per cent. upon the written down figure has been accepted (the amount to be allowed always being at the discretion of the Commissioners), the figure now generally accepted is 15 per cent. If, however, such a figure is not considered sufficient in any particular case, the Commissioners may, upon satisfactory evidence being placed before them, make such allowance as is fair and just. In the Tax Supplement of the *Accountant*, dated March 30th, 1929, a full list of wear-and-tear allowances for income-tax purposes is given, and in the issues of the same journal dated August 10th and 17th, 1929 (pp. 350 and 358 of the Tax Supplement), space is given to correspondence on the subject.

A NEW INFIRMARY AT DEWSBURY.—The work of the Dewsbury and District General Infirmary is this week being transferred to the new building on the Mirfields Estate, overlooking the town, the old building having been sold to the corporation. There are 97 beds and a new nurses' home. The cost, which was estimated at £130,000, is now expected to reach £150,000.

STUDENTS' GUIDE—SESSION 1930-1931

THE GENERAL MEDICAL COUNCIL.

POWERS, DUTIES, AND CONSTITUTION.

THE General Council of Medical Education and Registration of the United Kingdom is, first, a registering body: no person, even though his qualifications have been obtained by examination, is a *legally qualified* medical practitioner until his name appears in the Medical Register. Secondly, it is a standard-ing body, ensuring that medical education reaches an efficient minimum standard by scientific examination. Thirdly, it is a penal and disciplinary body, having power to remove from the Register any practitioner convicted of felony or misdemeanour or adjudged guilty of professional misconduct. Fourthly, to the Council is committed the codification of pharmaceutical remedies. The duties of the Council are thus primarily of a public nature, and its construction shows its fitness for its fourfold responsibilities.

The Council consists of 38 members, of whom all but 11 are official representatives of some corporate body. Five members are chosen by the Crown on the advice of the Privy Council, and six others are elected by the members of the medical profession as Direct Representatives. The Crown members need not be medical men and one layman now sits on the Council. Three members are appointed for dental business by the Privy Council under the Dentists Act, 1921, under which the powers and duties of the General Medical Council with regard to the keeping of the Dentists Register and the administration of the Dentists Acts were largely transferred to the Dental Board of the United Kingdom.

The Educational Curriculum.

Professional Education.—The course of professional study after registration as a student occupies at least five years. The Final Examination in Medicine, Surgery, and Midwifery must not be passed before the close of the fifth academic year of medical study.

REGULATIONS AS TO REGISTRATION OF MEDICAL STUDENTS.

Before registration as a student every candidate should produce evidence that (*a*) he has attained the age of 17 years; (*b*) that he has passed a recognised examination in general education; and (*c*) that, *in addition thereto*, he has passed, or obtained exemption from, an examination, theoretical and practical, in elementary physics and elementary chemistry conducted or recognised by a licensing body. The minimum standard of General Education required is that of University Matriculation or Entrance examination in the Faculties of Arts or Pure Science. In other Faculties the examination must be of the standard prescribed in Regulation 2 below.

An approved course of instruction in elementary biology at a secondary school or other teaching institution recognised by a licensing body may admit a student to the professional examination in elementary biology upon registration as a medical student. The student should in every case write beforehand to the Body whose qualification he desires to obtain, and, although it is not necessary to pass in Biology before registration as a student, application should be made at the same time to the Body selected to ascertain their requirements in regard to this subject.

The candidate commencing medical study should apply to the registrar of the division of Great Britain and Ireland in which he is residing, according to a prescribed form, copies of which may be had on application to the several licensing bodies, medical schools, and hospitals, or at the offices of the Council; and should produce proof that he, or she, has fulfilled the first three conditions.

MAINTENANCE OF REGISTER OF MEDICAL STUDENTS.

1. The Education Committee prepares and issues from time to time a list of examining bodies whose examinations in general education fulfil the conditions of, and are specially recognised by, the Council.

2. The Council has recognised the undernoted university examinations which are conducted in Great Britain and admit to the Faculties of Arts or Pure Science, or to other Faculties, subject to the conditions specified below:—

Oxford University, Responsions; Cambridge University, The Previous Examination. The Matriculation Examinations of the following Universities: Birmingham, Bristol, Durham, Leeds, Liverpool, London, Victoria of Manchester, Sheffield and Wales, and the Entrance or Preliminary Examination of the Universities of Scotland.

The condition prescribed by the Council in Faculties other than Arts or Pure Science is that:—

The certificate shall bear evidence that the candidate has passed in the Matriculation or Entrance standard, in the following subjects, viz.: (*a*) English. (*b*) Mathematics, Elementary. (*c*) A language other than English. (*d*) A fourth subject, as defined in the regulations of the particular Examination, to be chosen from the subjoined list, viz.: History, Geography, Physical Science, Natural Science; Botany, Latin, Greek, Hebrew, French, German, or other language accepted by the University for the purpose of matriculation or entrance.

3. Subject to the condition prescribed above (Section 2), the Council will recognise those of the examinations conducted by recognised authorities in Great Britain which are accepted by any one or more of the above-named Universities as equivalent (under prescribed conditions as to "credits" or "grades"), for purposes of Entrance or Matriculation, to an Examination named in the preceding list (Section 2). In School or Leaving Certificates, the four required subjects must have been obtained at not more than *two* sittings. Such Examinations are:—

Bristol University: Higher School Certificate Examination; School Certificate Examination. Cambridge Local Examinations Syndicate: Higher School Certificate Examination; School Certificate Examination. Central Welsh Examination Board: Higher Certificate Examination; School Certificate Examination. Durham University: Higher Certificate Examination; School Certificate Examination. London University: Higher School Certificate Examination; General School Examination. Northern Universities Joint Matriculation Board: Higher Certificate Examination; School Certificate Examination. Oxford and Cambridge Schools Examination Board: Higher Certificate Examination; School Certificate Examination. Oxford Delegacy for Local Examinations: Higher School Certificate Examination; School Certificate Examination. Scottish Education Department: Leaving Certificate Examination.

4. The Council will continue to recognise certain Examinations conducted by Educational Bodies, other than those (mentioned in Section 3) whose Examinations are accepted by any one or more of the Universities of Great Britain. Recognition will not be extended under this Section to any Examination unless the Council is satisfied (*a*) that in scope and standard it is equivalent to a recognised Matriculation or Entrance Examination of a University of Great Britain, (*b*) that it fulfils the condition prescribed by the Council (Section 2), and (*c*) that the Examination has been completed at not more than two sittings. Such Examinations are:—

The College of Preceptors (England): Senior Certificate (with *credit*). The Educational Institute of Scotland: Preliminary Medical Certificate.

5. Subject to the prescribed condition (Section 2), the Council will recognise the Entrance Examination to the School of Physic of the University of Dublin, and the Matriculation or Entrance Examinations of the National University of Ireland, the Queen's University of Belfast, the Irish Royal Colleges of Physicians and Surgeons; and also the Senior Grade or Leaving

Certificate of the Department of Education of the Irish Free State, the Senior Certificate Examination of the Ministry of Education of Northern Ireland, and all examinations accepted by any one or more of the Universities of Great Britain or Ireland. as equivalent, for purposes of entrance or matriculation, to the above-named University Examinations.

6. Subject to the prescribed condition (Section 2), the Council will recognise all Examinations of Colonial or Foreign Universities which are accepted by any one or more of the Universities of Great Britain as equivalent, for purposes of entrance or matriculation, to an examination named in the list of examinations recognised by the Council (Section 2).

7. The Council will recognise the Final Examinations for Degrees in Arts or Science of any University of Great Britain or Ireland or of the British Dominions.

8. The registration of medical students shall be placed under the charge of the Branch Registrars.

9. Each of the Branch Registrars shall keep a register of medical students.

10. The Branch Registrar shall enter the student's name and particulars in the Students Register, and give him a certificate of such registration.

11. Each of the Branch Registrars shall supply to the several licensing bodies, medical schools, and hospitals, in that part of Great Britain or Ireland of which he is Registrar, blank forms of application for the registration of medical students.

12. A copy of the Medical Students Register prepared by each of the Branch Registrars shall be transmitted, on or before Dec. 31st in each year, to the Registrar of the General Council, who will distribute the list to the licensing bodies, medical schools, and hospitals.

All applications for special exceptions to the foregoing regulations as to registration shall be addressed to the Registrar of the General Council, and shall be decided by authority of the Education Committee, who shall report thereon to the Council.

MEDICAL SCHOOLS AND COLLEGES.

The Universities, including their Colleges and Medical Schools, and Schools of Medicine at which Medical Study may be commenced in the United Kingdom are set out seriatim in the following pages.

Medical Registration in Ireland.

By agreement between the Governments of Great Britain, of the Irish Free State, and of Northern Ireland — since confirmed by legislature at Westminster and Dublin—the powers and duties of the General Council of Medical Registration and Education are continued as heretofore in respect of qualifying bodies in the Irish Free State, and of medical practitioners qualified in the Irish Free State. Side by side with this a Medical Council has been set up in the Irish Free State with the duty of establishing and controlling a Register for the Irish Free State. Practitioners whose names are on the General Register, and persons who pass a qualifying examination in the Irish Free State, will be registered on the Irish Free State Register on payment of the prescribed fee. The Irish Free State Medical Council have, over those whose names are on the Irish Free State Register, the same disciplinary powers as are possessed by the General Council over those whose names are on the General Register. To possess the privileges of a qualified practitioner in the Irish Free State it is necessary to be registered in the Irish Free State Register.

The net result of the change in the law as regards the practitioner qualifying in the Irish Free State in the future is that: (1) If he intends to practise only in the Irish Free State he need only register in the Irish Free State Register; (2) if he intends to practise in Great Britain he will register in the General Register; and (3) if he is in doubt where he will practise he will register in both Registers. He will, as he registers in one Register, or in both Registers, put himself under the disciplinary control of the one Council or of both Councils. No practical inconvenience is caused, and practitioners qualified in the Irish Free State in future will not find themselves deprived of any of the privileges or rights enjoyed by their predecessors.

Dental Board of the United Kingdom.

Anyone who is on the Medical Register is entitled to practise as a dentist, although he cannot register as such without degree or licence in dentistry; but it is a distinct advantage to take a special dental qualification, otherwise few dental appointments at general or special hospitals or dispensaries are available, and, unless registered in the Dentists Register, no dental work, under the additional Benefit Scheme of the National Health Insurance Act can be undertaken.

Under the Dentists Act, 1921, the powers and duties of the General Medical Council under the Dentists Act, 1878, and under the Medical Act, 1886, which related to the keeping of the Dentists Register and the administration of the Dentists Acts were largely transferred to the then newly constituted Dental Board of the United Kingdom. The registration of dental students at the commencement of their dental studies, and the right of erasure of a name from the Dentists Register, remain with the Council, but the duty of inquiring into disciplinary cases rests with the Board, upon whose recommendations the Council acts.

The Dental Board consists of a chairman and 12 members. The chairman is appointed by the Privy Council. Other members of the Board are appointed by the Minister of Health, the Scottish Board of Health, the Governor-General of Northern Ireland, the General Medical Council (3), Direct Vote of the qualified dentists practising in England and Wales, Scotland, and Ireland (3), Direct Representatives by dentists registered under the Dentists Act, 1921.

REGISTRATION OF DENTAL STUDENTS.

The General Medical Council's Regulations in regard to the registration of dental students which came into force on Jan. 1st, 1923, provide that the registration of dental students shall be carried on at the General Medical Council Office in London, in the same manner as that of medical students, and be subject to the same regulations as regards age and preliminary examinations; but in the case of dental students professional study may commence either at a recognised dental hospital or school, or by pupilage with a registered dental practitioner.

Candidates for a diploma in dental surgery should produce certificates of having been engaged for at least four years in professional studies, and of having received during 24 calendar months instruction in dental mechanics. It is recommended that instruction in dental mechanics be taken at a recognised dental hospital and school. If any part of such instruction be taken by the candidate as a pupil with a registered dental practitioner, the time required to be devoted to it shall be at least twice the time required for the corresponding instruction taken at a dental school. Two years' *bona-fide* apprenticeship with a registered dental practitioner, after registration as a dental student, may be counted as one of the four years of professional study. When a student can show evidence of regular pupilage for not less that two years in dental mechanics to a registered dental practitioner, prior to the passing of the prescribed preliminary and scientific examinations, he may be allowed to antedate his registration for a period not exceeding one year prior to the passing of these examinations.

Offices.

The address of the Registrar, to whom further communications should be addressed, is as follows: The Registrar of the General Medical Council, 44, Hallam-street, Portland-place, London, W.1. The offices of the Dental Board are adjoining.

A memorandum on the procedure to be adopted by those who desire to enter the profession of medicine, with notes on costs and prospects, and a similar Memorandum in regard to Dentistry, may be obtained on payment of 1*s*. each.

MEDICAL EXAMINING BODIES AND SCHOOLS IN ENGLAND AND WALES.*

UNIVERSITY OF OXFORD.

THERE are two degrees in Medicine, *B.M.* and *D.M.*, wo in Surgery, *B.Ch.* and *M.Ch.*, and diplomas in *Public Health*† and *Ophthalmology*. The examinations re open to men and women alike.

Only Graduates in Arts of the University are eligible or the Medical and Surgical degrees. The most onvenient course for the B.A. degree for intending raduates in Medicine is to take Responsions, the Preliminary Science Examinations mentioned below, nd the Final Honour School of Physiology. To btain the degrees of B.M. and B.Ch. the following xaminations must be passed: 1. Preliminary ubjects: Physics and Chemistry, Zoology, and Botany. 2. Professional. (*a*) First Examination: ubjects—Organic Chemistry, unless the candidate as satisfied the examiners in Part I. Chemistry in he Honour School of Natural Science; Human Physiology, unless he has obtained a First or Second lass in Animal Physiology in the Honour School of Natural Science; Human Anatomy. (*b*) Second Examination: Subjects—Medicine, Surgery, Midwifery, Pathology, Forensic Medicine with Hygiene, Materia Medica and Pharmacology. The First and econd Professional examinations are held in June nd December. The first B.M. examination may be assed at any time after the Preliminary Scientific xaminations. Anatomy and Physiology must be assed at the same time—Organic Chemistry may be aken separately.

At any time after passing *First B.M. Examination*, he candidate can, on producing certificates, present imself for examination in the subjects of Pathology, Forensic Medicine with Hygiene, Materia Medica and Pharmacology; but cannot, unless he is already a egistered medical practitioner, enter for examination n Medicine, Surgery and Midwifery until the eighteenth erm from his matriculation, nor until a period of at east thirty-three months has elapsed from the date f passing the First B.M. Examination. He must ass in Medicine, Surgery and Midwifery at one and he same time.

Before admission to the Examinations in Pathology nd Bacteriology, and Materia Medica and Pharmacology, of the *Second B.M. Examination*, the student ust produce certificates of having attended courses f instruction including practical work in Pathology, Bacteriology, Post-mortem Clerking, Pharmacology, nd Pharmacy, either in Oxford or in a recognised Medical School. Before admission to the remainder of he second B.M. Examination, he must produce a umber of other certificates, including certificates of aving acted as Clinical Clerk and Dresser, each for ix months in the Wards, of instruction in Midwifery nd of attendance on Labours, of instruction in Infectious Diseases and in Ophthalmology, of proficiency in Vaccination and in the administration of Anæsthetics, and of three academic years of hospital practice.

The degree of Bachelor of Surgery (B.Ch.) is granted with that of B.M. after passing the above examinations.

The degree of Doctor of Medicine (D.M.) is granted to Bachelors of Medicine of the University who have entered upon their thirtieth term rom Matriculation, and have submitted a dissertation which is approved by judges appointed for the purpose by the Board of the Faculty of Medicine. The degree of Master of Surgery (M.Ch.) is granted after examination to Bachelors of Surgery who have entered upon heir twenty-first term, and who are members of the urgical staff of a recognised hospital, or have acted as dresser or house surgeon in such a hospital for a period of six months. The examination, which includes Surgery, Surgical Anatomy and Pathology and Surgical Operations, is held annually in June, after the Second B.M. examination.

Travelling Fellowship, Scholarships, and Prizes.—A Radcliffe Travelling Fellowship is awarded annually after an examination held in February. It is tenable for two years and of the annual value of £300. The examination is in Physiology, Pathology, and Hygiene, and is partly "practical." Candidates must be graduates in Medicine of the University. The holder must travel abroad for the purpose of medical study. Application should be made to the Radcliffe Examiners, Department of Medicine, University Museum. A Schorstein Research Fellowship of the value of £200 a year, tenable for two years, is offered in alternate years. Candidates must be graduates of the University, under 35 years of age, and must hold a registrable medical qualification. Their research must be carried out in one of the Medical Departments at Oxford. A Christopher Welch Scholarship of £100, tenable for four years, is awarded annually after examination. Candidates must be men undergraduate members of the University, who have not exceeded the twelfth term from their matriculation, or been admitted to any degree in the University. They may offer any one of the subjects, Animal Physiology, Botany, Zoology. A George Herbert Hunt Travelling Scholarship of the value of about £100 is awarded every second year to enable a Bachelor of Medicine to undertake three months' study abroad. A Rolleston Memorial Prize is awarded once in two years to members of the Universities of Oxford and Cambridge of not more than ten years' standing for an original research in some Biological subject, including Physiology or Pathology. The Radcliffe Prize, founded by University College (1907), is of the value of £50 and is awarded biennially (alternating with the Rolleston Memorial Prize) for research in some branch of medical science. The Theodore Williams Scholarships, each of the value of £50 a year for two years, are awarded annually in the subjects of Anatomy, Physiology, and Pathology. A Radcliffe Scholarship in Pharmacology, of the value of £50 for one year, is awarded annually by the Master and Fellows of University College. A King's College Hospital Burney Yeo Scholarship of £80 is awarded each year on the nomination of the Regius Professor of Medicine. The Scholarships and Exhibitions in Science which are offered by most Colleges are open to those who intend to pursue Medicine. The value of these scholarships varies, according to the candidate's need, between £30 and £100 a year; the exhibitions vary in value from £30 to £100 per annum. The number of scholarships and exhibitions in Science offered annually is about forty. There are also Medical Scholarships of the value of £100 a year at University College and at Pembroke College. The Welsh Memorial Prize for Anatomical drawing is awarded annually, and is of the value of about £10.

More detailed information may be obtained from the University Calendar; from the Examination Statutes, 1929; from the Regius Professor of Medicine; from the Professors in the departments of medical science; and from the Dean of the Medical School, Oxford.

Radcliffe Infirmary and County Hospital.

There are 225 beds. Courses of instruction are given in connexion with the Oxford University Medical School. These include (1) a course in Practical Medicine by the Regius Professor of Medicine; (2) clinical lectures by the Litchfield Lecturers in Medicine and Surgery; (3) tutorial instruction and demonstrations in special Regional Anatomy (medical and surgical), methods of Medical and Surgical Diagnosis, and Surgical Manipulation; and (4) pathological demonstrations and instruction in post-mortem work are given by the Pathologist. Opportunities are offered to students who wish to act as surgical dressers and clerks. A post-graduate course is held in the hospital in the autumn of each year.

* For special diplomas see p. 490.
† Suspended until further notice.

UNIVERSITY OF CAMBRIDGE.

There are two degrees in Medicine, *M.B.* and *M.D.*, two in Surgery, *B.Chir.* and *M.Chir.*, and Diplomas in *Public Health*, *Hygiene*, *Tropical Medicine* and *Hygiene*, and *Medical Radiology and Electrology*. Students of Girton or Newnham College are admitted to the examinations for these degrees and diplomas.

The student must enter a College, or become a Non-Collegiate student, and keep nine terms (three years) by residence. He must pass the Previous Examination of the University before he comes into residence or therefrom obtain exemption, particulars of which may be obtained from the Registrary. He may then devote himself to medical study in the University. Or he may, as nearly all students now do, proceed to take a degree in Arts by passing the Examinations for the Ordinary B.A. degree, or an Honours degree by passing one or more Tripos Examinations. The Natural Sciences Tripos is taken most frequently by medical students, as some of the subjects are practically the same as those for the First and Second M.B. Examinations.

For the degree of Bachelor of Medicine (*M.B.*) five calendar years of medical study are required either in Cambridge or at one of the recognised Schools of Medicine. The first three years are spent in Cambridge till the student has passed the examination for Part I. of the Natural Sciences Tripos and the *First and Second M.B. Examinations*. Hospital practice may be attended at Addenbrooke's Hospital, Cambridge, after the student has passed Parts I. and II. of the *Second Examination*. The laboratories for Botany, Chemistry, Physics, Biology, Zoology, Human Anatomy, Physiology, Biochemistry, Pathology, Bacteriology, Pharmacology, Psychology, and Public Health are well equipped. Addenbrooke's Hospital, the Infectious Diseases Hospital, the Cambridge Research Hospital, and the Field Laboratories are utilised for study and research.

There are three examinations for M.B. The *First* includes (1) General and Inorganic Chemistry, (2) Mechanics, (3) Physics, and (4) Elementary Biology. These parts may be taken together or separately. The *Second* is divided into three parts—viz. (1) Organic Chemistry, (2) Human Anatomy and Physiology, and (3) Pharmacology and General Pathology. The *Third* is divided into two parts: (1) Principles and Practice of Surgery (including Special Pathology and Midwifery and Diseases Peculiar to Women); and (2) Principles and Practice of Physic (including Diseases of Children, Mental Diseases, Medical Jurisprudence), Pathology (including Hygiene and Preventive Medicine), and Pharmacology (including Therapeutics and Toxicology). The examinations are partly in writing, partly oral, and partly practical, in the hospital, in the dissecting room, and in the laboratories. An Act has then to be kept by the candidate reading an original dissertation composed by himself and being examined orally on some subject approved by the Regius Professor of Physic. Candidates who have passed both parts of the Third M.B. examination are admitted to the registrable degree of Bachelor of Surgery (B Chir). without separate examination and without keeping an Act.

The degree of Doctor of Medicine (M.D.) may be taken three years after that of M.B. or four years after that of M.A. The candidate is required to produce certificates of having been engaged in Medical Study for five calendar years, and if an M.A. to pass the same examinations as are required for the degree of M.B. An Act has to be kept, consisting of an original Thesis with *viva voce* examination; and a short extempore essay has to be written on a topic taken from the general subject of his thesis, whether it be Physiology, Pathology, Pharmacology, the Practice of Medicine, State Medicine, or the History of Medicine.

Candidates for the Degree of Master of Surgery (M.Chir.) who are M.A.'s may be admitted to the examination after they have become legally qualified under the *Medical Acts* to practise surgery. Others may be admitted to the examination when two years at least have elapsed after they have completed all that is required of candidates for the Degree of B.Chir. Candidates are required to pass an examination in Principles and Practice of Surgery, Surgical Anatomy and Surgical Operations, and Pathology, and to write an extempore essay on a Surgical Subject (Proposals are now before the University whereby the examination will be held once a year in February.

Diplomas are granted in Public Health, in Hygiene, in Tropical Medicine and Hygiene, and in Medical Radiology and Electrology. Candidates must hold a recognised medical qualification.

Scholarships and Prizes.—Medical studies are endowed by the numerous Natural Science scholarships at the various colleges, information about which can be obtained from the respective Tutors. There are Natural Science scholarships at most of the Colleges and prizes in the ancillary medical subjects. Some of these are entrance scholarships; some may be gained by students already in residence, and where suitable candidates are not forthcoming among such students the emoluments may be allotted to members of other Colleges. Valuable scholarships instituted on behalf of Medicine are the Tancred Studentships in Physic, tenable at Gonville and Caius College. The successful candidates must enter at the college within a month or remove there if they are members of any other college. Students are required to take the degree of M.B. as soon as they are of sufficient standing but may hold a Studentship for a further three years. Thus a student elected previous to admission to college can draw the emolument, the annual value of which is about £100, for eight years. Full particulars can be obtained from Mr. E. T. Gurdon, 28, Lincoln's Inn-fields, London. Among other scholarships and prizes may be mentioned the Balfour Studentship, for research in Biology, of the value of £300 a year for three years, not restricted to members of the University; the Frank Smart Studentship and Prizes for Botany and Zoology, and the Shuttleworth Studentship for Zoology or Physiology tenable at Gonville and Caius College. The one University prize in Medicine, the Raymond Horton-Smith Prize, is awarded to that candidate for the degree of M.D. who presents the best thesis for the degree during the academical year, provided that he has taken honours in a Tripos Examination.

An abstract of the Regulations and Schedules of the range of the examinations in Chemistry, Mechanics, Physics, Biology, Pharmacology, and General Pathology may be obtained upon application to the Registrary, The Registry, Cambridge.

Addenbrooke's Hospital.

Over 200 beds. Clinical Lectures in Medicine and Surgery, in connexion with Cambridge University Medical School, are given at this hospital twice a week during the academical year; and practical instruction in Medicine and Surgery is given in the wards and out-patients' rooms by the physicians and surgeons daily during the term time and vacations. The fee for pupilship is 3 guineas a term, 9 guineas a year, 12 guineas perpetual. Further information may be obtained from Mr. Vernon Pennell.

UNIVERSITY OF LONDON.

The University of London was constituted in 1836, reconstituted under the Act of Parliament, 1898, as a teaching as well as an examining body, and again reconstituted under Act of Parliament, 1926. All the metropolitan medical schools are constituent colleges while Clinical Units have been established at St. Bartholomew's, the London, St. Mary's St. Thomas', University College Hospital, and the Royal Free.

Internal and External Students.—All the examinations of this University are open to men and women alike. Matriculated students of the University may be either internal or external. Internal students of the University are students who are registered as pursuing a prescribed course of study, or an approved

urse of research, in a school of the University, or ıder teachers of the University. Centres for eliminary and intermediate medical studies have en established by the University at University and ing's Colleges. External students in addition to atriculating must register as preparing for an amination leading to a Degree or Diploma within e purview of the Council for external students.

niversity College.

University College has been constituted a Univer-y centre for the teaching of medical sciences. ıe College Faculty of Medical Sciences comprises e Departments of Physics, Chemistry, Botany, and ology (the Preliminary Medical Sciences); also e Departments of Anatomy, Histology, Physiology, ochemistry, and Pharmacology (the Intermediate edical Sciences). Research work is undertaken all departments. The completion of the building heme by the erection of the section for Anatomy, istology, and Embryology, together with further tensions to the Department of Physiology, which e generosity of the Rockefeller Foundation made ssible, provides exceptional facilities for research d post-graduate study in anatomy, physiology, d pharmacology. In particular might be specified e opportunities for investigation in human and mparative embryology and neurology, in histology, diology, anthropology, biochemistry, and experi-ental physiology and experimental embryology. rangements exist for the close correlation of the rk of the Faculty with University College Hospital d Medical School. Women students are admitted.

Scholarships and Prizes.—The first four items on e present list require a complete intermediate course University College. The money value and subjects examinations are as follows: (*a*) The Bucknill holarship, 160 guineas; (*b*) and (*c*) two Entrance hibitions, 55 guineas each, Chemistry, Physics, otany, and Zoology; (*d*) Entrance Scholarship, 0 a year for three years; (*e*) Cluff Memorial Prize, 5 biennially, Anatomy, Physiology, Pharmacology, d Chemistry; (*f*) Schafer Prize in Physiology, £18 ennially; (*g*) Sharpey Physiological Scholarship, 15, Biological Sciences; (*h*) Bayliss-Starling holarship, £120 a year, Physiology, Biochemistry; Morris Bursary for sons of deceased professional en, by nomination, tenable for two years, £20 a ar; and (*k*) five Gold and five Silver Medals arded annually in various departments. For rther information apply to the Secretary, Uni-rsity College, Gower-street, London, W.C.1.

ing's College.

The Medical Faculty at this College gives instruc-on in the subjects of Medical Science for the eliminary and Intermediate Examinations in edicine and Surgery, and Dental Surgery, of the niversity of London and of other Universities ıd examining bodies, to students entering the ollege directly, and also to students of the following ur hospital schools which prepare only for the ıal examinations—viz., King's College Hospital, estminster Hospital, St. George's Hospital, and aring Cross Hospital. The Faculty is open to oth men and women. Special courses in Anatomy ıd Physiology in preparation for the Primary xamination for the F.R.C.S. (England) are held vice yearly.

Scholarships and Prizes.—Two or more Warneford ntrance Scholarships of £30 each for four years. Exa-ination in April, subjects selected from Divinity, lassics, Science. Sambrooke Scholarship of £30 for ree years. Examination in April, subjects selected om Classics, Science. Worsley Scholarships: £100 in ve annual instalments of £20. *At the end of the irst Year* of study, the Rabbeth Scholarships (£30 ıd £15), the Carter Gold Medal and Prize in otany, and the Hare Prize in Zoology are open for mpetition. *At the end of the Third Year*, the Hughes rize in Anatomy, the Huxley Prize in Physio-gy, the Inchley Prize in Pharmacology, and ıe Jelf Medal are open for competition. The Layton and the Berridge Research Studentships (£150 per annum each), the Daniell Scholarship in Chemistry (£40), Warneford Prizes (£25 and £15), Leathes Prize, Barry Prize, &c., are also open to Students of this Faculty. The majority of the Scholarships and Prizes are open to Regular Students only. For further information apply to the Dean of the Medical Faculty.

Medical students of the University of London, who are pursuing their medical curriculum in the metropolis will proceed to one of the recognised medical schools connected with the University. At four of these schools the preliminary studies will be taken at King's College, while at the other schools the whole curriculum can be taken out in connexion with the selected hospital. These hospitals are St. Bartholomew's Hospital, Charing Cross Hospital, St. George's Hospital, Guy's Hospital, King's College Hospital, the London Hospital, St. Mary's Hospital, the Middlesex Hospital, St. Thomas's Hospital, University College Hospital, Westminster Hospital, and the London (Royal Free Hospital) School of Medicine for Women. Various schools and hospitals are also recognised as schools of the University in special departments, and students may pursue their studies at other approved universities and medical schools, presenting themselves for examination at the University.

The FACULTY OF MEDICINE of the University grants the joint degrees of M.B., B.S. (*Bachelor of Medicine and Surgery*), the higher separate degrees of M.D. (*Doctor of Medicine*) and M.S. (*Master of Surgery*), and the degree of B.D.S. (*Bachelor of Dental Surgery*) and the degree of B.Pharm. (*Bachelor of Pharmacy*); the two higher degrees being open only to candidates holding the M.B., B.S degrees of the University. The curriculum for the M.B., B.S. degrees is five and a half years from the time of matriculation, with certain exceptions which must be looked for in the official regulations of the University.

A. *Internal Students.*—For the Bachelor's degrees in Medicine and Surgery a student must normally, after registration as an internal student, have: (1) Attended prescribed courses of study for five and a half years in one or more schools of the University. (2) Passed the following examinations, under the conditions mentioned below: (*a*) The First Examination for Medical Degrees in Inorganic Chemistry, Physics, including Mechanics, and General Biology; (*b*) the Second Examination for Medical Degrees: Part I., Organic Chemistry; Part II., Anatomy, Physiology, and Pharmacology; (*c*) the Third Examination for Medical Degrees, or M.B., B.S. Examination in Medicine, Surgery, Obstetrics and Gynæcology, Pathology, Forensic Medicine, and Hygiene.

B. *External Students.*—For the Bachelor's degrees in Medicine and Surgery an external student must (1) have passed the Matriculation examination or have been exempted therefrom not less than five and a half years previously; (2) have passed subsequent examinations similar to those required of an internal student; and (3) have been engaged in professional studies during the five and a half years subsequently to Matriculation and four and a half years subsequently to passing the First Examination for Medical Degrees at one or more of the medical institutions or schools recognised by this University for the purpose, one year at least of the four and a half years to have been spent in one or more recognised institutions or schools in the United Kingdom.

The First Examination for Medical Degrees (Inorganic Chemistry, Physics, including Mechanics, and General Biology) will take place twice in each year, commencing on the Monday following Dec. 7th and on the first Monday in July. It must be passed not less than nine months after matriculation.

The Second Examination for Medical Degrees (Part I.): Organic Chemistry.—This examination will take place twice in each year, commencing on the Thursday following the second Monday in March and on the Thursday following the first Monday in July. No candidate will be admitted to this examination until he has completed the First Examination.

The Second Examination for Medical Degrees (Part II.) takes place twice in every year, commencing on the Tuesday following the third Monday in March and on the Tuesday following the first Monday in July. No candidate shall be admitted to the examination unless he has passed the First Examination for Medical Degrees at least 18 months previously, and has passed Part I. of the Second Examination for Medical Degrees.

The Third or M.B., B.S. Examination.—The M.B., B.S. examination takes place twice in each year, commencing on the second Monday in November and on the first Monday in May. No candidate will be admitted to this examination unless he has completed the Second Examination for Medical Degrees, together with a course of study summarised below, nor within three years from the date of passing the Second Examination, Part II., in Anatomy and Physiology. The course of study comprises introductory course in (1) Clinical Medicine; (2) Clinical Surgery; (3) Clinical Pathology; (4) Experience as Clinical Clerk; (5) Clinical Medicine; (6) (*a*) Fevers, (*b*) Children's Diseases, (*c*) Venereal Diseases, (*d*) Mental Diseases (at a recognised Asylum), (*e*) Dermatology, (*f*) Vaccination, (*g*) Materia Medica and Pharmacy; (7) Experience as a Surgical Dresser; (8) Clinical Surgery; (9) Ophthalmology; (10) Oto-Rhino-Laryngology; (11) (*a*) Operative Surgery, (*b*) Applied Anatomy, (*c*) Administration of Anæsthetics, (*d*) Dental Surgery, (*e*) Orthopædic Surgery, (*f*) Mechano-therapeutics; (12) Obstetrics and Gynæcology; (13) Lying-in Hospital; (14) The conduct of at least 20 Labours; (15) Antenatal Clinic; (16) Experience as a Clinical Clerk in Gynæcological Work; (17) General Pathology, Morbid Anatomy, Bacteriology, and Chemical Pathology; (18) Work in the Post-mortem Room; (19) Clinical Laboratory; (20) Forensic Medicine; (21) Hygiene. He must have attended the Medical and Surgical Practice of a recognised hospital for two years, and have held the posts of clinical clerk and surgical dresser for periods of six months each. Candidates will be examined in Medicine, Pathology, Forensic Medicine and Hygiene, Surgery, Obstetrics and Gynæcology. The subjects may be divided into two groups—namely: (1) Medicine, Pathology, Forensic Medicine, and Hygiene; and (2) Surgery, Obstetrics, and Gynæcology. These groups may be taken either separately or together, Bachelors of Medicine who graduated before May 1904, may obtain the B.S. by passing the Surgical part of the M.B., B.S.

Doctor of Medicine.—The examination for this degree takes place twice in each year, commencing on the second Monday in December and on the first Monday in July. Candidates may present themselves for examination in one of the following branches—namely: (1) Medicine; (2) Pathology; (3) Psychological Medicine; (4) Midwifery and Diseases of Women; (5) State Medicine; and (6) Tropical Medicine. Any candidate for the degree of M.D. (except in branch 5) may transmit to the Registrar a thesis for approval and may be exempted from a part or from the whole of the written examination.

Master of Surgery.—The examination for the degree of Master of Surgery takes place twice in each year: (1) Surgery; (2) Dental Surgery; (3) Ophthalmology; (4) Laryngology, Otology, and Rhinology. A thesis may be submitted as for M.D.

Doctor of Philosophy.—A Degree of Ph.D. has been instituted in non-clinical subjects for Internal and External Students in the Faculty of Medicine. Candidates for this degree must hold, in a branch of study akin to that in which they propose to proceed to the Ph.D. Degree, the Degree of M.B., B.S., or B.D.S., or B.Pharm., or B.Sc.

Bachelor of Pharmacy.—The course extends over three years.

Full details of the prescribed curricula can be obtained free on application to the Academic Registrar, or for External Degrees from the External Registrar, University of London, South Kensington, S.W. 7.

MEDICAL SCHOOLS OF THE UNIVERSITY OF LONDON.[1]

St. Bartholomew's Hospital and College.

The hospital contains 757 beds, of which 687 are fo patients in the hospital at Smithfield and 70 at th Alexandra Hospital, Swanley. Special department have been organised for Diseases of Women an Children, the Eye, Ear, Larynx, and Skin, as well a for Orthopædic and Dental Surgery, and for Electr therapeutics and X Ray work. Whole-time Clinica Units under Professors of Medicine and Surgery hav been established. A new Surgical Block of ten ward with accommodation for 250 patients, and connecte with a block of five new operation theatres is no in use.

Ten house physicians and ten house surgeon are appointed annually, are provided with room and board, and receive £80 a year as salary A resident midwifery assistant, an ophthalmi house surgeon, and a house surgeon for disease of the throat, nose, and ear, and a house surgeon fo orthopædic surgery are appointed every six month and are provided with rooms and board and receiv a salary of £80 a year. Three resident administrato of anæsthetics are appointed, the senior for on year at a salary of £150, and two juniors for si months with a salary at the rate of £80 per annun with board and rooms. An extern midwifery assistar is appointed every three months, and receives salary of £80 a year. The clinical clerks, th obstetric clerks, the clerks to the medical ou patients, the dressers to the surgical in-patien and to the out-patients, and the dressers in the speci departments are chosen from the students. residential College is attached to the hospital.

There are quarters for the resident staff, casualt medical, surgical, and special out-patient department casualty wards, dispensary, and clinical lectu theatre. There is a chemical laboratory attach to the College as well as a laboratory devoted instruction in Public Health. A block is devoted Pathology, and contains the post-mortem room well as extensive laboratories for bacteriology, clinic pathology, and pathological chemistry. *The Medic College Buildings* include three large lecture theatre a large dissecting-room, laboratories for chemistr biology, morbid anatomy and histology, and publ health, as well as a spacious library (containing 14,5 volumes), a well-appointed museum of anatom physiology, comparative anatomy, materia medic botany, and pathological anatomy. The path logical museum is complete. A new block in Giltspu street has recently been acquired and has been fitt up as lecture theatres and laboratories for physic chemical physiology, experimental physiology, hist logy, and pharmacology.

Special Classes for the Primary and Final F.R.C. are held twice yearly. *Instruction in Prelimina Science* is given to University of London students chemistry, biology, and physics throughout the yea Facilities for research work are afforded in the Clinic Units and Laboratories of pathological and oth departments.

Scholarships given in aid of Medical Study.—F five of the Scholarships and the Exhibition—name (*a*), (*b*), two Entrance Scholarships in Science the respective values of £75 and £100; (*c*) Entran Scholarship in Arts, £100; (*d*) Jeaffreson Exhibitio £50; and (*e*) Shuter Scholarship, £50—a full University course at St. Bartholomew's Hospital required. The awards of (*a*) and (*b*) are made aft examination in selections from the subjects Chemistry, Physics, Zoology, Botany, Physiolo Anatomy, and Pathology; (*c*) and (*d*) are award

[1] Of these schools that of the Royal Free Hospital is reserv for women; University College admits men and women the whole course, the number of women being limited; Kin College admits men and women to the intermediate subject the remainder admit men only.

ter examination in Mathematics, Latin or reek or French or German, a second language or hemistry or Physics; (*e*) is awarded after competitive xamination among Cambridge Graduates in Anatomy nd Physiology. The more important of the other cholarships and prizes are as follows:—Four Junior cholarships—(*f*) No. 1, £30, Anatomy and Physiology (*g*) No. 2, £20, Anatomy and Physiology; (*h*) No. 3, £25, Chemistry, Physics, and Biology; (*i*) No. 4, £15, hemistry, Physics, and Biology; (*j*) Senior Scholarship, £50, Anatomy, Physiology, and Chemistry; (*k*) irkes Scholarship, £30 and medal, Clinical Medicine; (*l*) and (*m*) two Brackenbury Scholarships, £39 each, ne in Medicine and one in Surgery; (*n*) Sir G. urrows Prize, 10 guineas, Pathology; (*o*) Skynner rize, 13 guineas, Regional and Morbid Anatomy; (*p*) Matthews Duncan Medal and Prize, £20, Midwifery nd Gynæcology; (*q*) Luther Holden Research cholarship in Surgery, awarded by election, £105; (*r*) Lawrence Research Scholarship and Gold Medal Pathology, awarded by election, £115; and (*s*) Baly Scholarship in Clinical Medicine, £75, warded by examination.

The recreation ground of 10 acres is at Winchmore ill for the use of the members of the Students' nion, which all students are expected to join. The tudents' Union contains a large reading and smoking oom, a committee and writing room, luncheon and ining hall, and a miniature rifle range.

Information may be obtained on application to the ean of the Medical College, Mr. W. Girling Ball. The Warden of the Residential College is Mr. R. M. Vick.

haring Cross Hospital.

The Hospital, to which the School is attached, ontains 300 beds. There are special departments r Mental Diseases, Midwifery, Diseases of Women, Children, of the Skin, Ear, Throat, Nose, and Teeth, r Orthopædic Cases, X Ray work, and for Electrical reatment.

In the Medical School Demonstratorships and ssistant Demonstratorships are open to students the School. Six House Physicians, six House rgeons, two Obstetric and Gynæcological House rgeons, and four House Surgeons to the Special epartments are appointed annually. The large roportion of resident appointments to the number students makes it probable that a student of rdinary ability will be able to obtain one of these ppointments.

The following appointments are open to students ter they have held resident appointments: Resident edical Officer, at a salary of £400 per annum; egistrar to the Medical, Surgical, Obstetrical and Ear, ose, and Throat Departments, at £150 per annum.

By an agreement with the University of London ne School sends its Primary and Intermediate tudents to receive their lectures and practical work King's College, which is situated within four minutes' alk.

Final studies are taken in the school and hospital, here systematic lectures, demonstrations, and itorial classes are arranged to cover all the subjects ecessary for qualifying examinations. Departments re also available for other final subjects of Materia edica and Operative Surgery.

An Institute of Pathology with a whole-time staff scientific workers and fully equipped laboratories as been established. Students receive their training Preventive Medicine, Pathology, Bacteriology, and iochemistry here, and are encouraged to undertake search. Special facilities are available for post-raduate research and study.

The course in Ophthalmology is given in the Royal Westminster Ophthalmic Hospital. Special demonrations are arranged for Post-graduates.

One Epsom School Scholarship, two Oxford and ambridge Scholarships, and one Scholarship in natomy and Physiology open to students of King's ollege, are offered for competition each year. In ddition there are a number of Exhibitions.

The Museum contains over 4000 specimens, including a notable collection of over 800 gynæcological specimens, the Cuthbert Lockyer Collection.

The social comfort and convenience of students are met by library, reading, and smoking-rooms, refreshment-room, in a Students' Club. The Club, which is under the control of a committee of students, provides needful athletic recreation, and includes also a medical society.

Further information may be obtained on application to the Dean, Mr. E. A. Crook, M.Ch., F.R.C.S.

St. George's Hospital.

This hospital has a service of 436 beds, of which 180 are allotted to surgical, 150 to medical cases, and 100 are at the Convalescent Hospital at Wimbledon. There are all the usual special clinical departments. One ward is set apart for Diseases Peculiar to Women, and there is a Maternity Ward of 11 beds. Children's beds are placed in the women's wards. There are two ophthalmic wards.

Twelve house physicians, 12 house surgeons, and 12 casualty officers are appointed annually. Special attention is directed to the following paid appointments, among others, which are open to students after they have held house office:—Resident Assistant Physician and Resident Assistant Surgeon, at £250 per annum each; Medical Officer to the Atkinson-Morley Convalescent Hospital, at £300 per annum; Medical Registrarship at £200 per annum, Surgical Registrarship at £200; Assistant Curatorship of the Museum at £100; Obstetric Assistantship (Resident) at £100; the post of Resident Anæsthetist at £100; the posts (3) of Junior Anæsthetists, each at £30.

Entrance Scholarships and Endowed Prizes of a total value of £968 are awarded annually; a detailed list is placed below. The entire teaching and laboratories are now devoted to purely clinical subjects, and arrangements have been made with the authorities of King's College for students who enter the first, second, or third year of the curriculum as students of St. George's to carry out the necessary courses of instruction at that College. Students then complete their course, without payment of any entrance fee, in a school entirely devoted to clinical work.

Scholarships and Prizes.—At this school 11 entrance scholarships and exhibitions are given, the money value and the subjects of examination being as follows: (*a*) and (*b*) two William Brown Exhibitions, £120 and £80 respectively; (*c*) and (*d*) two Anne Selina Fernee Scholarships, £80 each; (*e*) Devitt-Pendlebury Scholarship, £50; (*f*) and (*g*) two Anne Selina Fernee Exhibitions, £40 each, Anatomy and Physiology, except in the case of (*c*) and (*f*) subject of examination for which is General Pathology.

In addition to the above Exhibitions, each of the value of £40 and up to four in number, will be awarded to candidates of approved merit in the Entrance Scholarships Examination. The others are as follows: (*h*) Allingham Scholarship in Surgery for Students qualified not more than two years, £87; (*i*) and (*j*) two Brackenbury Prizes, one in Medicine and one in Surgery, £33 each, open to students of not more than five years' standing; (*k*) H. C. Johnson Memorial Prize, £20, Practical Anatomy; (*l*) Pollock Prize, £24, Physiology, Physiological Chemistry, and Histology; (*m*) Clarke Prize, £5; (*n*) Thompson Medal, £9, Clinical Reports; (*o*) Brodie Prize, £8, Clinical Reports; (*p*) Webb Prize, open to perpetual pupils, £34, Bacteriology; (*q*) Sir Francis Laking Memorial Prize, £65, open to students having registrable qualifications.

The St. George's Hospital Club, with smoking- and luncheon-rooms on the hospital premises and an athletic ground at Wimbledon, is an amalgamation of the Hunterian Society, the *Gazette*, and the Rugby football, cricket, lawn tennis, boxing, rifle, and golf clubs. Students have the advantage of a library of medical and scientific books which is kept up to date.

Further information may be obtained from the Dean of the Medical School, Dr. A. Feiling.

Guy's Hospital.

The Medical School, which has been entirely rebuilt within recent years, provides ample accommodation with modern equipment for all the non-clinical subjects of the medical curriculum. The School is a constituent part of the University of London and offers a complete medical education of University standard throughout. The Hospital contains 646 beds, a total which is more than sufficient to provide the clinical material necessary to ensure that the students in the clinical period are given every opportunity to obtain a practical knowledge of clinical work. On commencing the clinical period, students are placed for three months under the charge of an experience Clinical Tutor while they are given a preliminary course of instruction in methods of clinical examination. Thereafter, they hold a series of appointments, each of three months duration, in surgical, medical, and obstetrical and gynæcological wards. Students are signed up after each appointment by the members of the staff to whom they have been attached. The type of instruction is essentially practical and students are given a larger amount of individual responsibility, provided that they show themselves worthy of it.

The following special departments are attached to the hospital: Departments of ophthalmology, laryngology, gynæcology, diseases of children, diseases of the nervous system, dermatology, otology, actiontherapeutics, anæsthetics, dentistry, orthopædics, vaccine, tuberculosis, genito-urinary and venereal diseases, Salomon's Welfare Centre (for Maternity and Children). Dresserships and clerkships in the various special departments are held by students after they have completed their general medical and surgical and their obstetrical and gynæcological appointments.

There is a Venereal Clinic, in accordance with the Scheme of the Local Government Board and London County Council. Lectures and clinical instruction are given, to which Medical Students and Practitioners are admitted without fee.

House physicians, house surgeons, out-patient officers, assistant house surgeons, obstetric residents, house surgeons in the departments of ophthalmology, laryngology, and genito-urinary diseases, house physicians in the departments for neurology and dermatology and for diseases of children, and clinical assistants are appointed from among recently qualified students according to merit.

Scholarships. — Six entrance scholarships are awarded annually as follows:—(*a*) one War Memorial scholarship, of the value of £200, to be awarded alternately in Arts and Science (next award, June or July, 1932, in Arts); (*b*) one Open Arts Scholarship of £100 for students under 19 years of age; candidates are required to take English and any two of the following subjects: Latin, Greek, French, German, and Mathematics; (*c*) one Open Junior Science scholarship for students under 20 years, £100; subjects, any three of the following: Inorganic Chemistry, Physics, Biology, and Mathematics; (*d*) a confined Junior Science scholarship of the value of £100 is offered for competition, annually in June or July, to candidates who have attended the Preliminary Science Classes at this School; (*e*) two open Senior Science scholarships: (1) a War Memorial scholarship of the value of £100, awarded annually in September: (2) an open scholarship of the value of £80, awarded annually in September, for students who have completed the curriculum for, or passed the examinations in, Anatomy and Physiology for a medical degree in any University of the British Empire, and who, during the nine months immediately preceding the Scholarship examination, have not entered as students in any Metropolitan Medical School other than Guy's; subjects, any two of the following: Anatomy, Physiology, Organic Chemistry and Pharmacology, General Pathology.

Within the grounds of the hospital are situated the residential college, with accommodation for 35 students, the students' club, with reading, smoking, luncheon, and dining-rooms, a fives court, and swimming bath. The athletic ground and club house is situated at Honor Oak Park, and can be reached in 15 minutes from the hospital.

Further information, together with full particulars of Scholarships, and a booklet entitled "How to Enter the Medical Profession," will be sent post free on application to the Dean of the Medical School Guy's Hospital, London, S.E. 1.

King's College Hospital.

The final subjects in the curriculum are taught at the Medical School of King's College Hospital, which is situated at Denmark Hill, S.E. 5.

The hospital has 400 beds, and provision will be made ultimately for 600. There are special departments for Bacteriology, Cardiology, Children, Clinical Pathology, Dermatology, Gynæcology and Obstetrics, Laryngology, Massage, Medical Chemistry, Neurology, Odontology, Ophthalmology, Orthopædics, Otology, Physical Treatment, Psychological Medicine, Radiology, Rhinology, and Urology, each in charge of a specialist and his staff.

Appointments.—The appointments open to students are those of clinical assistant to the general and special departments; medical, surgical, obstetric, and pathological tutorships; resident casualty officers; house physicians and house surgeons; resident anæsthetist; resident radiologist; bacteriologist; clinical pathologist; pathological, medical, surgical, and obstetrical registrarships. Sixteen resident medical and surgical officers are appointed half-yearly.

Scholarships and Registrarships (those in connexion with King's College have already been enumerated).—Scholarships of the total value of £1530 are awarded annually. These include (*a*) Medical Entrance Scholarships—Science, £75; Anatomy and Physiology, £75; Pathology, £75; (*b*) two Burney Yeo Entrance Scholarships, £80 each, open to students of Oxford and Cambridge on the recommendation of the Regius Professors; (*c*) two Raymond Gooch Scholarships, £120 each, open to students of British Universities on certain conditions; (*d*) Epsom College Scholarship, value £100, offered annually to a student of Epsom College who has taken the first part of the courses for Medical Degrees at the Universities of Oxford, Cambridge, or London; (*e*) two Seamen Scholarships, each £50 a year for a period not exceeding five years, restricted to the sons of clergymen of the Church of England; (*f*) Senior Scholarship (Clinical Studies), £40. The holders of the Warneford and Sambrooke Scholarships awarded by King's College take the subjects of the preliminary and intermediate examinations at King's College, and the final subjects at King's College Hospital. Three Sambrooke Registrarships, open to matriculated students who have filled certain appointments in hospital.

Prizes.—Tanner Prize, £10, Obstetrics and Diseases of Women; Todd Prizes, First £8 and medal, second £4, for Clinical Medicine; Burridge Prize, £4 4s. Forensic Medicine; Jocelyn Almond Prize, £5 5s. Diseases of Children; Wallis Prize, £10, History of Dentistry; The Ferrier Prize in Neurology, Bronze Medal and £20. 13 Class Prizes, £3 each.

The King's College Hospital Clubs and Societies Union consists of the Listerian and Musical Societies, the Students' Common Rooms, and the various athletic and sports clubs. The athletic ground, over six acres in extent, is on Dog Kennel Hill, about ten minutes' walk from the hospital. There are also Tennis Courts in the grounds of the Hospital and of "The Platanes"—a hall of residence for students of the College and the hospital.

The Calendar of the School will be sent on application to either of the following: Dr. H. Willoughby Lyle, Dean; Mr. S. C. Ranner, Secretary of the Medical School.

ondon Hospital.

The hospital, with its Medical College and Dental chool, is situated in Mile End-road, and contains 39 beds which are in constant use. The Hospital the largest in England. Its position in the neighourhood of the extensive docks, factories, and orkshops of the East of London renders it one of ie most important hospitals in the world. During 929, 89,972 patients were attended to in the Receiving oom and the Out-Patient Departments, and in the ards 13,992 patients received treatment. The ondon Hospital presents, therefore, a large field for inical Instruction, and in its Wards and Out-patients' oms exceptional opportunities are afforded for quiring an extensive and practical experience of all ases of disease. There are special departments for ie treatment of diseases of Children, the Eye, Ear, ose and Throat, Skin and Teeth. In addition ere are departments devoted to Gynæcology and bstetrics, Orthopædics, Cardiography, Radiology, lectro- and Physico-therapeutic Light Therapy, adium, and Vaccine Therapy. The Special Departents are attended by a large number of patients, id afford to the student the means of becoming perienced in every branch of practice. The recent ditions have greatly increased the efficiency with hich the Clinical Teaching can be given.

A Clinical Unit in Medicine, under the charge of whole-time director, provides for the more elaborate ethods of diagnosis and treatment, and takes a ading part in the initiation and coördination of edical research. The director has an assistant rector, two assistants, and two house physicians.

To each medical and surgical firm throughout the spital there is attached a First Assistant, who is sponsible for instructing the clerks or dressers of ie firm in elementary medicine and surgery, and ho assists the honorary members of the firm in ie preparation of their demonstrations. In the partment of Obstetrics and Gynæcology there are vo assistants and two resident accoucheurs. Special urses of lectures and demonstrations are arranged Medicine and Surgery and their ancillary subjects. pportunities for research are provided under the pervision of the staff.

Owing to the large number of patients more appointents are open to students before and after qualificaon than at any other hospital. Holders of resident ppointments have free board. Special classes are ld for the examinations of the University of London, r the Fellowship of the Royal College of Surgeons, r the Membership of the Royal College of Physicians, id for other higher examinations. Special entries for edical and surgical practice can be made.

The salaried appointments open to past students the hospital are those of assistants to the medical nit; first assistants to the medical and surgical ms; assistants to the departments of obstetrics and næcology; clinical assistants in the medical, surgical, phthalmic, aural, light and skin, orthopædic, and ectrical departments, and in the Institute of Pathogy and Clinical Laboratory. There are appointed nually four resident accoucheurs, 14 resident house ysicians, and 22 resident house surgeons, 14 resident ceiving-room officers, 8 resident emergency officers, clinical assistants to the medical out-patient departent, and 16 clinical assistants to the surgical outtient department, also paid and unpaid clinical sistants in the various special departments.

Scholarships and Prizes.—Entrance Scholarships: rice Scholarship £100, and one Scholarship of £50, bjects of First Medical Examination at the niversity of London; Epsom College Scholarship, ee education, subjects of First Medical Examination above; Price Scholarship, open to students of xford and Cambridge Universities, (1) £100, thology; (2) £100, Human Anatomy and Physiogy; two Open Scholarships, each of the value of 00, subjects, Human Morphology and Embryology, ysiology and Pharmacology, Biochemistry, Pathogy, Bacteriology and Morbid Anatomy. Prizes: Buxton Prize, £40, subjects of Anatomy and Physiology; three Prizes for Clinical Work, £20 each, Medicine, Surgery, and Obstetrics and Gynæcology; Sutton Prize, £20, Pathology; Duckworth Nelson Prize, biennial, £10, Practical Medicine and Surgery; Letheby Prizes (2), £25, Chemistry and Chemical Pathology; four Dressers' Prizes, amounting to £20, zeal, efficiency, and knowledge of Elementary Clinical Surgery; Hutchinson Prize, triennial, £60, Clinical Surgery; Treves Prize, £15, Clinical Surgery; two Practical Anatomy Prizes, £6 and £4 respectively; Andrew Clark Prize, £14, Clinical Medicine and Pathology; T. A. M. Ross (Prox. Acc.) Prize, £10 10*s.*, Clinical Medicine and Pathology; James Anderson Prizes (4), £20, Elementary Clinical Medicine; Arnold Thompson Prize, £15, Diseases of Children; and Liddle Prize, triennial, £120.

Medical Research Funds.—Funds to the value of over £113,000 permit of financial assistance being given to students and graduates engaged in Medical Research.

A laboratory for the manufacture of certain preparations of Radium has recently been endowed.

A Residential Hostel is provided for students, and a hostel for resident medical officers. The Union Athletic Ground, 13 acres, is within easy reach of the hospital.

Dean: Prof. William Wright, M.B., D.Sc., F.R.C.S.

St. Mary's Hospital.

The Hospital and Medical School have on one side a poor district of 500,000 persons, and on the other side the residential districts of Kensington and Bayswater. The hospital contains 350 beds, and recent structural additions have added two new operating theatres. By a scheme of affiliation, for teaching purposes, of certain neighbouring hospitals, the teaching facilities extend over 1000 beds. The Medical School provides complete courses of instruction, and students can join at once on passing a Preliminary Examination in Arts. Terms begin in October, January, and April.

Clinical Units in Medicine and Surgery were established in 1920. Under this system Professors of Medicine and Surgery, with competent assistants, give their whole time to teaching and research. This means a regularity of teaching and a degree of individual attention that are only possible where Units exist. The system also provides additional salaried posts which are open to students after qualification.

Teaching of Midwifery.—The Hospital has lying-in beds, and in addition to the instruction thus obtained each student attends a short course at Queen Charlotte's Hospital, as part of his training in Midwifery, without additional fee. Under the new building scheme it is proposed to institute additional lying-in wards.

Students specially interested in Pathology and Bacteriology have singular advantages at St. Mary's. The institute comprises seven special departments, the whole being under the personal direction of Sir Almroth Wright. Certain Research Scholarships of £200 each are awarded annually to students working in the departments of the institute; and research beds have been instituted. Clerkships in Pathology, Bacteriology, and Chemical Pathology, lasting for a period of three months, are open to students of the fifth year, and enable them to carry out the Pathological and Bacteriological investigations of the wards, and learn the necessary technique under supervision. Seventy-two of these posts are available annually. Numerous appointments are open to newly qualified members of the Medical School, including ten salaried posts with salaries varying from £200 to £750 per annum. A special Post-graduate course is held during the first week-end in October, and is open to all General Practitioners and other qualified men without fee.

Entrance Scholarships.—Two Entrance Scholarships of the value of £210 each are awarded annually, by nomination in July, the Geraldine Harmsworth Scholarship, £200, and one or more University Scholarships of £200 are awarded in July.

The Athletic ground (10 acres) is situated at Wembley and can be reached in 20 minutes by a constant service of trains. A large pavilion has recently been added.

Rebuilding of the Medical School.—The site for the rebuilding of the Medical School and Inoculation Department has already been cleared, and building operations will be commenced shortly. The new School will contain departments for the teaching of all Preliminary and Intermediate subjects, and will include a student's club, dining and billiard rooms, and a gymnasium and swimming bath.

For further information apply to the Dean of the Medical School.

Middlesex Hospital.

The hospital and cancer wing contain over 470 beds, with special wards for Cancer, Maternity, Gynæcological, Otological, Neurological, and Ophthalmological cases, and for Diseases of Children. Other special departments include those for Diseases of the Eye, Ear, Nose and Throat, and Skin; Nervous Diseases, Orthopædic cases, Diseases of the Rectum and Venereal Diseases. There is also an Electrotherapeutic department. The Cancer Wing, containing 92 beds and Special Investigation Laboratories, offers unrivalled opportunities for the study of Cancer, both in its clinical and pathological aspects. In the Electrotherapeutic Department, students obtain instruction in the Treatment of Lupus and Cancer by the X ray method of treatment.

All appointments are made without fee of any kind, and the following are appointed at intervals annually: six house physicians, eight house surgeons, two obstetric and gynæcological house surgeons, two casualty medical officers, two casualty surgical officers, one senior resident anæsthetist, two junior resident anæsthetists, and four resident officers to the special departments. Ten registrars are appointed annually. Non-resident qualified clinical assistants are appointed to assist in the various out-patient departments. Clinical clerks and surgical dressers are also appointed in every department.

The Medical School, which includes the Bland-Sutton Institute of Pathology, the Courtauld Institute of Biochemistry, and the Barnato-Joel Laboratories, is fully equipped for the theoretical and practical teaching of all the subjects of the medical curriculum, for the Diplomas in Public Health, and the University of Cambridge Diploma in Radiology, for which two courses are held yearly. Ample laboratory and classroom accommodation is provided. The teaching staff includes 6 Professors, 32 recognised Teachers, 10 Demonstrators, 4 Tutors. The Bland-Sutton Institute of Pathology and the Courtauld Institute of Biochemistry are completely equipped for routine hospital investigations, teaching and research work, and contain large pathological, bacteriological, and clinical laboratories, also smaller laboratories for individual research work. A well-equipped Anatomical and Pathological Museum and Reference Library offer every facility.

Other features of interest are: the course in Medical Radiology and Electrology, under the direction of the "Joel" Professor of Physics; D.P.H. course, under the direction of Dr. Charles Porter, M.O.H., St. Marylebone, Prof. J. McIntosh, and Prof. W. B. Tuck. A primary F.R.C.S. course is held twice yearly, and also special classes to prepare students for the Intermediate Examinations of the Universities.

Scholarships and Prizes.—Two Entrance Scholarships, value £100 each, and two University Scholarships, value £90 and £60, are awarded annually in September. The successful candidates are required to become general students of the school. A Freer Lucas Scholarship is awarded annually on the nomination of the Headmaster of Epsom College. There are also two Broderip Scholarships, value £60 and £40 respectively; the Lyell Gold Medal and Scholarship, value £55 5*s.*; the John Murray Medal and Scholarship, value £25 (awarded every third year); the Freeman Scholarship, value £30; the Hetley Clinical Prize, value £25; the Leopold Hudson Prize, value 11 guineas; and the Second Year's Exhibition value 10 guineas. There are numerous class prizes.

The Students' Amalgamated Clubs include the following: Medical Society, Common Room Society, Musical Society, cricket, football, rowing, chess, lawn tennis, hockey, sailing, and fencing. There are a restaurant and a gymnasium in the school buildings and athletic grounds at N. Wembley, with pavilion.

For further particulars apply to the Dean or the Secretary of the Medical School.

St. Thomas's Hospital.

This Hospital contains 644 beds. There are special departments for the treatment of women children, diseases of the eye, ear, nose and throat skin, teeth, and for orthopædics. Nervous and mental diseases are treated in special departments An electrocardiograph has been installed for the investigation of diseases of the heart. The Tuberculosis Department forms a part of the Lambeth scheme for treatment of patients and for instruction The Venereal Department has been established as part of the London County Council scheme. Departments for Radiology, Electrotherapy, Phototherapy Massage and Remedial Physical Exercises are also special features. A speech clinic has been inaugurated in connexion with the Children's Department Exceptional facilities are offered in the hospital laboratories for the study of General Pathology, Clinical Pathology, Chemical Pathology, and of Treatment by Serums and Vaccines. Surgical operations take place in the main theatres every day. Clinical teaching in the wards, out-patients' and special departments, is available every day of the week Clinical lectures are delivered every Wednesday during the sessions. Clinical Units in Medicine and Surgery have been established.

All appointments in the hospital are open to students without extra fee. Clinical clerks and dressers for in- and out-patients are selected from students who have completed their third years' work Every student acts as clerk in the post-mortem room and in one of the pathological laboratories, takes his turn on maternity duty under proper supervision in the maternity ward and district, thus obviating any necessity for seeking instruction elsewhere. Students are instructed in the administration of anæsthetics by the hospital anæsthetists.

The arrangements are made to meet the requirements of all the Examining Bodies. Special classes are held for the examinations at the University of London and for the First and Final Fellowship Examinations of the Royal College of Surgeons of England. Tutorial classes in all subjects precede the various examinations. The hospital is easily accessible from all parts.

Appointments.—A Resident Assistant Physician and a Resident Assistant Surgeon, salary £225 each per annum, and a Resident Anæsthetist, salary £200 per annum, are appointed annually. Three medical and two Surgical Registrars at a salary of £250 rising to £300 hold their appointments on a tenure renewable to a maximum of four years. A Pathological Registrar to the Department of Obstetrics and Gynæcology (at an annual salary of £250), an Ophthalmic Registrar (at an annual salary of £200) and an Orthopædic Registrar (unpaid) are appointed yearly. Eight Resident Casualty Officers and Anæsthetists are appointed every six months. Seven House Physicians (including two Obstetric House Physicians, and one House Physician to the Department of Diseases of Children), nine House Surgeons (including two Ophthalmic House Surgeons, one Orthopædic House Surgeon, and two House Surgeons to the Ear, Nose and Throat Department) are appointed every six months. Clinical Assistants in the Special Departments are appointed every three months, and hold office for six months if recommended for re-election. There are three Assistants in the Depart-

ent of Pathology; the Senior receives £600 a year, id the two Juniors £450 each.

Scholarships and Prizes.—At this school there are ie following Entrance Scholarships—namely, two Arts, equivalent to the tuition fees for the first ar of study; two in Natural Science, of the value of 50 and £60 respectively; and the University holarship of £100 in any two of the following: natomy, Physiology, Pathology, Chemistry, also ie "Hector Mackenzie" University Exhibition of ie value of £40. The value of all entrance scholar-ips must be taken out in tuition fees. The money alue and subjects of examination of the remainder e as follows: (*a*) William Tite Scholarship for cond-year students, £25; (*b*) and (*c*) Musgrove holarship or (alternately) Peacock Scholarship ch for third-year students and tenable for two ars, £35 each; (*d*) Mead Medal, Medicine, Pathology id Hygiene; (*e*) Wainwright Prize, Medicine; (*f*) oller Prize, Medicine; (*g*) Cheselden Medal, Surgery id Anatomy; (*h*) Clutton Memorial Medal in inical Surgery, biennial; (*i*) Beaney Scholarship, 50, biennially, Surgery and Surgical Pathology;) Solly Medal and Prize, biennial, Reports of Cases;) Sutton Sams Prize, biennial, Report of Cases; Bristowe Medal, Pathology and Morbid Anatomy;) Hadden Prize, Pathology and Morbid Anatomy;) Grainger Testimonial Prize, £31 10*s.*, Anatomy id Physiology; (*o*) Louis Jenner Research Scholar-ip, tenable for two years, £60 annually, Pathology. St. Thomas's House, the New Students' Club cently opened, comprises spacious dining-, smoking-, id reading-rooms, and accommodation for some resident students. There is no occasion for students leave the hospital premises during working hours. Further information may be obtained from the edical Secretary of the School, St. Thomas's Hospital.

niversity College Hospital.

The final subjects in the curriculum are taught at e Medical School of the hospital, which has 526 beds, cluding 74 in the new obstetric hospital. The course instruction is suitable for the examinations at the niversities of Oxford, Cambridge, Durham, and other ritish Universities, and for the medical education quired by the Examining Board in England and the ociety of Apothecaries. Clinical Units in Medicine, rgery, and Obstetrics and Gynæcology are now in eration. The whole-time Directors of the Units are ncerned with the organisation of the teaching gener-ly, but the honorary staff are responsible for the rgest share of the teaching in the wards and Out-tient Department of the hospital. The department otology, rhinology, and laryngology (the Royal Ear ospital) has been provided with a separate building Hunter-street, adjacent to the obstetric hospital. contains 39 beds, including eight private wards for tients of limited means. The hospital is equipped th all modern appliances for investigation. The w buildings of the Obstetric Hospital of 74 beds ndered possible by the Rockefeller Benefaction), e new Residents' House (with accommodation for residents and students), the extension to the Nurses' ome, and new research laboratories for the Medical hool are now finished and in full occupation. Twelve omen students are admitted annually.

Those who are desirous of carrying out original search in Pathology, including Morbid Anatomy, cteriology, Experimental Pathology, and Chemical thology, are admitted to work in the labora-ries of the school by the Professor of Pathology, d under certain conditions can receive grants from e Charles Graham Medical Research Fund. A ecial course of instruction is given in conjunction th University College for preparation for the exam-ations for Diplomas in Public Health of the various iversities and examining bodies. In the Dental hool in Great Portland-street, formerly known the National Dental Hospital, there is afforded e opportunity for attending lectures and practical struction in diseases of the mouth and teeth.

Appointments.—Clerkships and dresserships to the physicians, surgeons, anæsthetist, and pathologist are allotted amongst the students of the hospital. Maternity students are appointed each month and reside in the Students' House connected with the Medical School and Hospital. Sixteen house physicians, ten house surgeons, ten obstetric assistants, four house surgeons to the Royal Ear Hospital (of the total number of resident officers not more than three may be held by women students at any one time) are selected annually by examination from among the senior students who have a medical qualification. All house officers reside free in the hospital. In addition to these posts there are certain special appointments which are vacant from time to time and are filled by senior students of the hospital: Resident Medical Officer, Surgical Registrar, Medical Registrar, Obstetric Registrar, Harker-Smith Cancer Registrar, Ophthalmic Registrar, Registrar to the Royal Ear Hospital, Casualty Medical Officer and a Casualty Surgical Officer, Assistants in Ear and Throat, Skin and Venereal Diseases Departments, and House Anæsthetist.

Assistants to Medical, Surgical, and Obstetric Units.—These salaried appointments which have come into existence recently at the same time as the creation of the whole-time Chairs in Medicine, Surgery, and Obstetrics, are of great value to senior students who may desire to remain at Hospital after holding the ordinary resident appointments. They enable a man to continue clinical work and also to devote time to laboratory or other research, so as to fit himself for higher posts in the profession. The salaries range from £250 up to £900 a year, resident quarters being provided only for the chief assistant to the Obstetric Unit. The total number of such Assistantships varies from time to time, being generally about 12, and an aggregate sum of about £5000 annually is available for their salaries.

Scholarships and Prizes (those in connexion with University College have already been enumerated).—At this School the first two Scholarships (*a*) and (*b*) entitle the holder to a complete course at University College and University College Hospital Medical School; the second two (*c*) and (*d*) entitle to a final course at the Medical School. The money value and subjects of examination are as follows:—(*a*) Entrance Scholarship, Bucknill, 135 guineas, Chemistry, Physics, Botany, and Zoology; (*b*) Epsom Free Medical Scholarship, subjects of Preliminary Scientific Examination and Nomination by Epsom College; (*c*) and (*d*) two Goldsmid Entrance Exhibitions 112 guineas each, Anatomy or Physiology, or General Pathology; (*e*) Graham Scholarship in Pathology, £300 per annum for two years, awarded by the Senate of the University of London; (*f*) Atkinson Morley Scholarship, tenable for three years, £45 per annum, Surgery; (*g*) Atchison Scholarship, tenable for two years, £55 per annum, General Proficiency in Medical Studies; (*h*) Magrath Clinical Scholarship, about £150, Clinical Cases; (*i*) Percival Alleyn Scholarship, about £75, Surgery; (*j*) Filliter Exhibition, £30, Pathology; (*k*) Erichsen Prize, £10 10*s.*, Practical Surgery; (*l*) two Senior and two Junior Fellowes Clinical Medals for Clinical Medicine; (*m*) two Liston Gold Medals for Clinical Surgery; (*n*) Alexander Bruce Gold Medal for Pathology and Surgery; and (*o*) Tuke Silver and Bronze Medals for Pathology. (*p*) Radcliffe Crocker Travelling Scholarship for Dermatology. (*q*) Leslie Pearce Gould Travelling Scholarship for Surgery.

The *Museum of Pathological Anatomy* is open for study daily, and microscopic sections of most of the specimens have been prepared and are available for the use of students on application to the Curator. The Anatomical Museum of the University of London, University College, is open to all students of University College Hospital and Medical School on the recommendation of the School Committee. The Medical Library, open daily to every student of the School, contains about 20,000 works on medical subjects,

including all the current text-books and works of reference required for study or research.

The Medical Society of University College Hospital Medical School exists for the dual purpose (1) of promoting the study of medical and surgical science, and (2) of promoting social intercourse among its members. All male students of the Medical School are required to become members. Meetings are held once a fortnight for the purpose of discussing subjects connected with the study of medicine. In its social aspect the society includes various athletic clubs and superintends the gymnasium and squash racquet courts in the Medical School, and the Athletic Ground at Perivale.

University College Hall, Ealing, is recognised by the authorities as a residential hostel. The Students' House in University-street contains large and comfortable rooms. The Maternity Students occupy them on payment of a moderate charge.

Full information can be obtained from the Dean of the School.

Westminster Hospital.

The Hospital contains 248 beds, and has attached to it a Radium Clinic with 22 beds, elaborately equipped for all forms of Radium Therapy and Research. There are separate departments for diseases of the eye, skin, teeth, ear, nose and throat, for orthopædic practice, for diseases of women, for diseases of children, for radiography, for venereal disease, and for massage, electrical and light treatment. The anatomical, pathological, and materia medica museums are open to all students of the School.

The entire teaching of the Hospital is devoted to the subjects of the Final Examinations. Arrangements are made for the tuition required for Preliminary and Intermediate subjects.

Appointments: Paid appointments as Medical, Surgical, and Obstetric Registrars, Casualty Officers, House Physicians, House Surgeons, Anæsthetist, &c., are available for students when they have passed their examinations.

Research: There are excellent opportunities for Research work in the recently endowed John Burford Carlill Laboratories. Grants to assist Research workers are made annually from the John Burford Carlill Endowment.

Fees: Annual fee, £40. An entrance fee of 10 guineas includes membership of the Sports Union Club with its various branches—i.e., football, cricket, tennis, boxing, and Guthrie Society. The Athletic Grounds are situated in Tooting and are reached in 20 minutes from the hospital.

Scholarships and Prizes.—The following Entrance Scholarships are offered for competition: Winter Session: Two Scholarships in Anatomy and Physiology, £75 each. Summer Session: Two Scholarships in Anatomy and Physiology, £75 each. A certain number of Scholarships have been allotted to Universities of England, Wales, and the Colonies, and to Public Schools. These Scholarships are awarded entirely on the nomination of the principal of the university or school. During the period of study the following prizes may be competed for: Sturges Prize in Clinical Medicine, about £6, Reports on Cases; Chadwick Clinical Surgery Prize, £5, Reports on Cases; Chadwick Prize, £21 in books or instruments—Medicine and Surgery, including Pathology and Applied Anatomy and Physiology; Frederic Bird Medal and Prize, open to Fourth-year Students, £14 in medal and books or instruments—Midwifery, Diseases of Women, Medicine, Pathology, Forensic Medicine and Bacteriology, and Public Health and Toxicology; Abrahams Prize in Clinical Pathology 5 guineas, a Paper and Tests in Practical Work; Hanbury Prize in Diseases of Children, 10 guineas; Alfred Hughes Memorial Prize, open to Second-year Students, about £5 in books or instruments—Anatomy; Huxley Memorial Prize, 3 guineas in books or cash, open to Second-year Students—Physiology; Carter Gold Medal and Prize for Botany, open to Students of not more than three years' attendance, gold medal and books of the joint value of £15; Jelf Medal awarded to Third-year Students; Second year Scholarship £20, Elementary Anatomy, Physiology, Histology and Organic Chemistry; Daniel Scholarship, £40, Chemistry; Rabbeth Scholarship open to First-year Students, one of £30 and one of £15 Class Examinations in the Preliminary Scientific Course. Inquiries should be addressed to the Dean of the Medical School.

Royal Free Hospital: London School of Medicine for Women.

The Royal Free Hospital contains 268 beds. The Hospital also has large Casualty and Out-patient Departments. A Children's Department, including 18 cots, an Orthopædic Department, and a Light Department have recently been added to the Hospital. Maternity Districts are attached to the Unit operating in the Gray's Inn-road and Essex-road areas. Students also attend the in-patient and out-patient practice at the Elizabeth Garrett Anderson Hospital, Cancer Hospital, Hospital for Sick Children, Great Ormond-street, National Hospital, Queen Square, South London Hospital, and Royal London Ophthalmic Hospital.

A Clinical Unit in Obstetrics has been established controlling 68 beds. Courses are arranged for the Primary Fellowship Examination of the College of Surgeons. The Eastman Dental Clinic, for which Mr. George Eastman, of Rochester, N.Y., has provided the building fund, is in course of erection and will provide a Dental School for women; at present the course for dental students is in conjunction with the Royal London Dental Hospital, Leicester-square.

The School buildings have been entirely rebuilt in recent years, and there are spacious, well-equipped laboratories, which afford every facility for efficient of teaching and practical work in all departments.

There are residential chambers in the neighbourhood and the Warden can be consulted on the subject.

Students after qualification can hold the posts of house physicians, house surgeons, obstetric assistant, clinical assistants, assistant anæsthetist, medical, gynæcological, and surgical registrars, and assistant pathologist; and at the Medical School the posts of demonstrators in the departments of Anatomy, Physiology, Pharmacology, Biology, Chemistry, and Physics.

Scholarships and Prizes.—Among the larger of the awards are the following:—(*a*) Isabel Thorne Scholarship, £30. (*b*) St. Dunstan's Medical Exhibition, £ a year, tenable for three or five years. (*c*) M. George M. Smith Scholarship, £50 a year, tenable for three or five years. (*d*) Bostock Scholarship, tenable for two or four years, £90. (*e*) Mabel Sharman Crawford Scholarship, tenable for four years, £20 a year. (*f*) Sir Owen Roberts Scholarship, £ a year for four years. (*g*) Mabel Webb Research Scholarship, tenable for one year and renewable, £30. Physiology, Chemistry, or Pathology. (*h*) Fanny Butler Scholarship, tenable for four years; next award in July, 1931, £16. (*i*) John Byrne Bursary, tenable for two years, for students already in the School requiring assistance for the prosecution of their medical studies; application to the Secretary by March 31st next, £20. (*k*) Helen Prideaux Prize and Julia Ann H. Cock Prize, to be spent in assisting the newly qualified holder to further study, £60 each. (*l*) Dr. Edith Pechey Phipps Post-graduate Scholarship of the value of £1 open to all medical women, preferably coming from India, or going to work in India. (*m*) Sarah Holborn Scholarship, value £20 a year for three or five years, awarded every alternate year; next award in 1931. (*n*) Dr. Margaret Todd Scholarship, tenable for four years, £37 10*s.* a year, awarded in alternate years; next award in July 1931. (*o*) Lieutenant Edmund Lewis and Lieutenant Alan Lewis Memorial Scholarship, tenable for four years, awarded every four years; next award in July 1932. (*p*) Alfred Langton Scholarships, tenable for years, one awarded annually, £50 a year. (*q*) Schola Jubilee Bursary, tenable for three years, £50 a year.

r) Flora Murray Bursary, awarded every year to a ifth-year student, £50. The Dorothy Chick Gift, 20, is awarded annually for efficiency in Practical Midwifery. The Students' Union arranges the social, thletic, and other clubs and societies.

Inquiries may be addressed to the Warden and Secretary of the Medical School, 8, Hunter-street, London, W.C.

UNIVERSITY OF DURHAM.

The University of Durham grants degrees of Bachelor of Medicine, Bachelor of Surgery, Doctor of Medicine, Master of Surgery, Doctor of Surgery, Bachelor of Hygiene, Doctor of Hygiene, Bachelor of Dental Surgery and Master of Dental Surgery, a Diploma in Public Health, Diploma in Psychiatry, and a Licence in Dental Surgery.

For the degrees of *Bachelor of Medicine* and *Bachelor of Surgery* there are four professional examinations. The subjects of the First Examination are—Elementary Biology and Organic Chemistry. The subjects of the Second Examination are—Anatomy and Physiology. The subjects of the Third Examination are—Pathology and Bacteriology, Materia Medica, Pharmacology and Pharmacy, Medical Jurisprudence, and Public Health. The subjects of the Fourth Examination are—Medicine, including Therapeutics, Clinical Medicine, Surgery, Clinical Surgery, Operative Surgery, Midwifery and Gynæcology, Psychological Medicine, Diseases of the Skin, of the Throat, Nose, and Ear, and of Children, and Ophthalmology. It is required that at least one of the five years of professional education shall be spent at the University of Durham College of Medicine, Newcastle-upon-Tyne.

For the degrees of *Doctor of Medicine* and *Master of Surgery* a candidate must not be less than 24 years of age. He must also have obtained the degrees of Bachelor of Medicine and Surgery of the University of Durham, and must have been engaged for at least two years subsequently to the date of admission to these degrees in research work, or in attendance on the practice of a recognised hospital, or in the naval or military services, or in medical or surgical practice. The candidate for the M.D. degree may present an essay or undergo a special examination in the subjects of Medical Anatomy, Medical Pathology, and the Principles and Practice of Medicine. The subjects of examination for the M.S. are:—Principles and Practice of Surgery, Surgical Pathology, Surgical Anatomy, Surgical Operations, Clinical Surgery.

Doctor of Medicine (without residence).—The University of Durham instituted a special examination whereby the degree of Doctor of Medicine may be obtained without residence. Candidates must not be under 40 years of age and must have been in active practice for 15 years as registered medical practitioners. They must also produce certificates of moral character from three registered members of the medical profession. The fee is 50 guineas (including the degree fee), of which 20 guineas is retained if the candidate fails to satisfy the examiners.

Attention is particularly directed to the fact that the Senate of the University on the 4th February, 1930, decided that this examination should not be held after June, 1932.

Doctor of Surgery.—The University of Durham grants the Degree of Doctor of Surgery. Candidates for this degree must be registered medical practitioners, and not less than 25 years of age. They must devote three years, subsequently to obtaining a registrable qualification, to the study of Surgery and ancillary subjects. One at least of the three years must be spent in the University. The candidate must submit to the Professor of Surgery the course of study he proposes to follow, and this course must be approved by the Board of the Faculty of Medicine. One year shall be devoted mainly to work in the departments of Anatomy, Physiology, Pathology, and Bacteriology, and the candidate must submit evidence of having so worked. Not less than six months of another year must be spent as resident surgeon in a recognised teaching hospital, and the rest of the year in the study of surgery in a recognised medical centre. Not less than six months of one of the three years must be spent in surgical study abroad.

Candidates for any of the above degrees, diplomas, or licence must give at least 28 days' notice to the Secretary of Examinations, University of Durham College of Medicine, Newcastle-upon-Tyne. In the case of the M.D. (essay) examination candidates must send in their essays before April 1st.

Scholarships and Prizes.—The following are awarded:—University of Durham Entrance Scholarship, £25 a year for four years; Pears' Entrance Scholarship, £40 a year for three years (awarded every third year); Heath Entrance Scholarship (from Kepier Grammar School), £60 (renewable); Province of Durham Masonic (Entrance) Scholarship, £60 (renewable); Heath Scholarship for Surgery, £200, available every second year; Rutherford Morison Surgical Scholarship, £180, available every third year.

The following Scholarships are tenable for one year, namely:—Tulloch Scholarship for Elementary Biology and Organic Chemistry, £20; Dickinson Scholarship for Medicine, Surgery, Midwifery, and Pathology; Gold Medal and £20; Charlton Scholarship for Medicine, £25; Gibb Scholarship for Pathology, £28; Luke Armstrong Scholarship for Comparative Pathology, £25; Stephen Scott Scholarship for Surgery, £40; Philipson Scholarships for highest marks in Final M.B., B.S. Examinations, two of £45 each; Goyder Memorial Scholarship for Clinical Medicine and Clinical Surgery, interest on £325; Gibson Prize for Midwifery and Diseases of Women and Children, £10; Turnbull Prize and Silver Medal for Surface Anatomy; and Outterson Wood Prize for Psychological Medicine, £10; Sewell Memorial Prize and Silver Medal for Clinical Pathology.

For further information apply to the Dean of the College.

Newcastle-upon-Tyne: College of Medicine.

Hospital practice is carried out at the Royal Victoria Infirmary, a general hospital containing more than 550 beds, and there are facilities for the study of the various special subjects.

Practical midwifery can be studied at the Princess Mary Maternity Hospital, which contains 90 beds, with an annual indoor and outdoor attendance on 3000 cases.

The bacteriological laboratory is adjacent to Armstrong College.

Post-graduate Instruction.—A comprehensive series of post-graduate courses have been arranged to enable practitioners to take advantage of the facilities for laboratory work and clinical study afforded by the College, the Royal Victoria Infirmary, and the Princess Mary Maternity Hospital; and in order to meet the varied requirements of practitioners there are general and special courses in the winter and summer sessions and an intensive course in the summer vacation.

A *Students' Union* has been erected and furnished at a cost of over £54,000, and is now in daily use. Special accommodation has been provided for women students.

Royal Victoria Infirmary.

The Infirmary has 576 beds. Clinical Lectures are delivered by the Physicians and Surgeons weekly and ward demonstrations are given daily. Tutorial classes are given by the Assistant Physicians, Assistant Surgeons, the Medical and Surgical Registrars, and the Assistant to the Gynæcological Department, and demonstrations are given in the several out-patient departments daily. Pathological demonstrations are given by the Pathologist daily or as opportunity occurs, and in the new buildings nothing has been spared in perfecting scientific equipment. In addition to medical and surgical in-patient and out-patient departments the following special departments are fully equipped for teaching students: Ophthalmic,

Throat, Nose, and Ear, Skin, and Venereal Disease, Gynæcological, and Electrical. The hospital building contains the following laboratories: 1. Special Pathological Laboratory, attached to the post-mortem rooms. 2. Bacteriological Laboratory in which all clinical bacteriological investigations are carried out. 3. There is in addition a Clinical Laboratory attached to each ward and to the out-patient department. There are five operating theatres in use in the hospital. The winter session of 1930 opens on Sept. 25th and the summer session of 1931 on April 9th. Applications for detailed information should be made to the Sub-Dean, Dr. Horsley Drummond, at the hospital.

Practical Midwifery is studied at the Princess Mary Maternity Hospital, which has 90 beds and a large extern department. Instruction is given in Psychological Medicine at the City of Newcastle Mental Hospital. A special course of instruction is given in the City Hospital for Infectious Diseases by the City Officer of Health.

Post-graduate Instruction.—1. General courses in Clinical Medicine, Surgery, and Pathology at the Royal Victoria Infirmary, meeting once weekly for ten weeks. One course will be held from October to December and one from April to June. 2. Special courses of clinical instruction, meeting once weekly for ten weeks, in the following subjects: Gynæcology; Diseases of the Eye; Diseases of the Throat, Nose, and Ear; Diseases of the Skin; Venereal Diseases; Neurology; Diseases of Children; Electrotherapeutics and Radiology; special courses in Midwifery will be held at the Princess Mary Maternity Hospital. 3. An intensive course of 14 days' duration in the early part of the Summer Vacation. 4. In addition to the regular post-graduate courses practitioners may attend the ordinary medical and surgical practice of the Royal Victoria Infirmary, and also at the Princess Mary Maternity Hospital, for specified periods.

UNIVERSITY OF BIRMINGHAM.

The University of Birmingham grants the degrees of M.B., Ch.B., M.D., Ch.M., and Ph.D. (for Research Study), and also a degree and a diploma in Public Health. The course for the Bachelors' degrees, including the subjects of Physics, Chemistry and Biology, extends over six years. The Senate has power of recognising attendance at another University as part of the attendance qualifying for these degrees and of recognising examinations passed at such other Universities as exempting from the examinations in Physics, Chemistry, Biology, and Organic Chemistry; but at least three years must be spent in attendance upon classes in the University. The final year may be spent at any other medical school recognised by the University.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—The student must have passed the Matriculation Examination of the Joint Board or an examination accepted in lieu thereof. Before commencing the study of Anatomy and Physiology, examinations in Chemistry and Physics and Biology must be passed (First M.B., Ch.B., Parts I. and II.), or examination in lieu thereof. All communications respecting the Matriculation Examination, and examinations accepted in lieu thereof, must be sent to the Secretary, Joint Matriculation Board, 315, Oxford-road, Manchester. Second Examination.—Part I., Organic Chemistry; Part II., Anatomy and Physiology. Third Examination.—General Pathology and Bacteriology. Fourth Examinations (at the end of the fifth year).—Forensic Medicine and Toxicology; Public Health; and Materia Medica, Pharmacology, and Therapeutics. Two years' hospital work must have been accomplished. Final Examination.—Medicine, Surgery, Midwifery and Diseases of Women, Mental Diseases, and Ophthalmology. Attendance at a general hospital for a year after the passing of the fourth examination will be required, also attendance at a fever hospital three months, maternity hospital three months, and mental hospital three months. Vaccination instruction must be taken and course of Ophthalmology, Venereal and Skin Diseases and Diseases of Ear, Nose, and Throat, Medica and Surgical Anatomy, and Operative Surgery. Distinctions may be awarded in the subject (severally) of the Second, Third, Fourth, and Final and First- and Second-Class Honours in the Fina Examination.

Degrees of Doctor of Medicine and Master of Surgery. At the end of one year from the date of havin passed the final M.B., Ch.B. examination the cand date will be eligible to present himself for the highe degrees of either Doctor of Medicine or Master o Surgery or both. Candidates have to present thesis on some subject embraced in the medica curriculum, and pass a general examination in Prin ciples and Practice of Medicine for the M.D. and on in Principles and Practice of Surgery, including opera tions on the cadaver, for the Ch.M., or, at the discretio of the examiners, in a special branch of Medicine o Surgery respectively. A thesis of exceptional mer may exempt from any part of these examination in which Honours may be awarded.

Degree of Ph.D.—The Degree of Doctor of Philo sophy is conferred upon candidates who possess medical degree of a British, Colonial, or other unive sity approved of by the Senate of the University, an who have been engaged, to the satisfaction of th Medical Faculty, in advanced study and research fo a period of not less than two years, either in a labora tory of the University or in one or more of the hospita associated with the University. After the first ye candidates may carry on research elsewhere, unde approved conditions, and on completing the cours present a thesis and submit themselves for oral an possibly written examination.

Scholarships and Prizes.—The following ar awarded:—Entrance Scholarships: (*a*) Frank Fletch and Catherine Fletcher Scholarships of £100 p annum each, for five years. Two or more offere annually; open to men and women students und certain prescribed conditions as to residence, &c (*b*) Sydenham Scholarship of £42, tenable for thr years, award of Council to orphan sons of medic practitioners; (*c*) Sands Cox Scholarship of £21 p annum during two years, awarded to the candidat not being more than 19 years of age, taking th highest marks at the Higher School Certificate Exam nation of the Joint Matriculation Board; (*d*) Dent Scholarship of £46 17*s.* 6*d.*, Open Competitive Examin tion in subjects learned during apprenticeshi (*e*) Myers Travelling Studentship of £300, tenable f one year, offered in alternate years, awarded by vo of committee to M.B., Ch.B. candidates, tenable some University or Hospital not in Great Britain Ireland (available for year 1930-31); (*f*) two Ingle Scholarships of £10 each, awarded to the candidat at Final Examination obtaining highest "first-class marks in the subjects of Midwifery and Diseases Women; (*g*), (*h*), (*i*), and (*j*) Four Queen's Schola ships of £10 10*s.* each, awarded to the candida taking the first place in the Second, Third, Fourth, an Final Examinations respectively, provided that t candidate's work is sufficiently distinguished; (Priestley Smith Prize in Ophthalmology, value abo £6 10*s.*, is awarded annually to the student passi the Final M.B., Ch.B. Examination on first ent who shows the best knowledge of Ophthalmolog provided the Examiners deem him worthy of th distinction. (*l*) George Henry Marshall Scholarsh of £10, awarded annually, for the encouragement Research Work in Ophthalmology; and (*m*) Russ Memorial Prize, a prize of books, value about £ awarded annually to the Student who, not being more than six years' standing as a student of th School of Medicine of the University, shall pass th best examination in the subject of Nervous Disease The "Arthur Foxwell Memorial Medal" (Gold Med for Medicine) is awarded annually to the candida taking the highest place in Clinical Medicine and pa ing the Final M.B., Ch.B. Examination in June; a

he "Sampson Gamgee Memorial Medal" (Gold Medal for Surgery) is awarded annually to the best candidates passing Final M.B., Ch.B. Examination in June in Surgery provided that not less than 60 per cent. of marks is obtained (paper, oral, and clinical). The University Clinical Board awards Gold and Silver Medals on examinations in Medicine, Surgery, and Midwifery, respectively, in fourth and fifth years, open to all students.

Clinical Instruction.—The medical students of the University receive their clinical instruction by attending the amalgamated practice of the General Hospital, Queen's Hospital, Maternity Hospital, Children's Hospital, Mental Hospital, and Fevers Hospital, under the direction of the University Clinical Board. Appointments are open to students varying from £40 to £200 a year.

Post-graduate Instruction.—A "William Withering Lectureship" has been established. A course (or courses) of lectures is given annually for post-graduates on subjects chosen from year to year. In 1931 the lectures will be given by Sir Hubert Bond, Commissioner of the Board of Control. The Ingleby Lectures on some subject in connexion with Diseases of Women and Children are given annually by specially appointed lecturers: The Lecturer for year 1931 is Prof. W. Blair Bell, of Liverpool. Post-graduate Courses of Clinical Demonstrations for General Practitioners are arranged annually (April to July) at the Birmingham General, Queen's, and Children's Hospitals.

Queen's Hospital.

There is a close association of this Hospital (330 beds) with the University of Birmingham, and the University clinical teaching is conducted here, there being a wealth of excellent material. Ward rounds and out-patient clinic classes are held daily, and there are regular tutorial classes throughout the session. Post-graduate courses arranged by the University are conducted every year. There are special departments in Gynæcology, Diseases of the Eye, of the Ear, Nose and Throat, Dentistry, Radiography, Pathology, Bacteriology, Biochemistry, Physiotherapy, and Electrocardiography. There are also large Wards for Midwifery and Postnatal cases, Nursery for instruction in Infant Welfare, an extensive Midwifery District and residential facilities for students. There are 23 Resident Appointments (exclusive of Registrars) available each year for recently qualified students.

Birmingham General Hospital.

There are 406 beds. Special wards for Children, Gynæcological, Ear and Throat, Venereal, Maternity, and Septic cases; special beds for Eye and Skin cases. Laboratories for Bacteriology, Biochemistry, Cancer Research, and Morbid Histology. Separate rooms adjoin the medical and surgical wards for clinical pathology. Five operating theatres (one for out-patients), all designed and fitted on modern lines. In addition to clinical teaching given in the wards and out-patient department by the honorary staff, medical and surgical tutorial classes are held for senior and junior students. Clinical instruction in all the special departments, which include those for Radium, Electrotherapy, Electrocardiographic investigation, and Venereal Diseases. Post-graduate classes in every branch of medicine and surgery. The Jaffray Branch Hospital contains 61 beds.

Birmingham and Midland Eye Hospital.

There are 115 beds. Students attending for a period of three months will be granted certificates which will qualify for the University and Conjoint Board examinations. Post-graduate courses are available. A limited number of Non-Resident Clinical Assistants' posts are open to qualified practitioners, particulars of which can be had on application to the General Superintendent. This Hospital has a very large Out-Patient Department.

UNIVERSITY OF LIVERPOOL.

The degrees in the Faculty of Medicine are Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Doctor in Philosophy (Ph.D.), Master of Surgery (Ch.M.), Master of Hygiene (M.H.), and Master of Orthopædic Surgery (M.Ch.Orth.).

Matriculation.—Candidates for the degrees in Medicine and Surgery are required (*a*) to have satisfied the examiners in the several subjects of the Matriculation examination or to have passed such other examination as may from time to time be recognised for this purpose by the Joint Matriculation Board; (*b*) to have included Mathematics among the subjects in which they have passed at such examination.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Candidates for the degrees of Bachelor of Medicine and of Surgery must have attained the age of 22 years on the day of graduation. At least two of the six years of medical study must have been passed in the University, and one year at least must have been passed in the University subsequently to the date of passing the First Examination. The other three years may be passed at any college or medical school recognised for this purpose by the University. Candidates must pass three examinations entitled respectively: the First Examination, the Second Examination, and the Final Examination. The subjects of the First Examination are: (1) Chemistry; (2) Biology (Zoology and Botany); (3) Physics; (4) Special Chemistry. The subjects of the Second Examination are (*a*) (1) Anatomy; (2) Physiology (including Physiological Chemistry and Histology); and (*b*) (3) Elementary Bacteriology, (4) Clinical Chemistry, (5) General Pathology. Candidates may present themselves in (*a*) or (*b*) separately. The subjects for the Final Examination are: (*a*) (1) Special Pathology and Morbid Anatomy; (2) Forensic Medicine and Toxicology; (3) Public Health; (4) Pharmacology and General Therapeutics; (*b*) (5) Obstetrics and Diseases of Women; (6) Surgery, Systematic, Clinical, Operative and Practical, including Ophthalmology; (7) Medicine, Systematic and Clinical, including Therapeutics, Mental Diseases, and Diseases of Children. Candidates may present themselves in Parts (*a*) and (*b*) separately, but candidates must have completed the fifth year of medical study before taking Part (*b*).

Degrees of Doctor of Medicine and Master of Surgery. No candidate will be admitted to the degree of Doctor of Medicine or Master of Surgery unless he has previously received the Degrees of Bachelor of Medicine and Bachelor of Surgery, and at least two years have elapsed since he passed the examinations for those degrees. Candidates may also take the degree of Doctor of Medicine by examination after five years from taking Liverpool M.B., Ch.B. Candidates for the degree of Doctor of Medicine are required (*a*) to present a thesis, acceptable to the Faculty, and certified to be the candidate's own work, together with (if the candidate desires) copies of published original papers upon Medical Science; (*b*) to present themselves for an oral examination on the subject of the thesis.

The University also awards a *Diploma in Medical Radiology and Electrology*—Part I., Physics: Part II., Radiology and Electrology. The parts may be taken at one examination or separately.

Scholarships, Fellowships, and Prizes.—The following are awarded: (*a*) Robert Gee Entrance Scholarship (Men), annually, of £42 10*s.*, tenable for four years; (*b*) Lyon Jones Scholarship, No. 1, of £21 per annum, tenable for two years, Competitive Examination among Junior Students in First M.B. Subjects; (*c*) Lyon Jones Scholarship, No. 2, of £21, Competitive Examination on results of Professional Examination in Anatomy, Physiology, Elementary Bacteriology, Clinical Chemistry, and General Pathology; (*d*) Derby Exhibition of £15, Competitive Examination in Clinical Surgery, and (*e*) Clinical School Exhibition of £15 in Clinical Medicine; (*f*) University Scholarship of £50 for

one year, awarded on results of the Final (Part A) Examination for the degrees; (*g*) Holt Fellowships, Physiology and Pathology, of £150 each, for one year; (*h*) Gee Fellowship, Anatomy, of £100, for one year; (*i*) John Rankin Fellowships in Anatomy, two, each of the value of £120, tenable for two years; (*j*) Johnston Colonial Fellowship, Biochemistry, of £100, for one year; (*k*) John W. Garrett International Fellowship, Bacteriology, of £100, for one year; (*l*) Thelwall Thomas Fellowship, Surgical Pathology, of £200, for one year; (*m*) Ethel Boyce Fellowship in Gynæcology, of £100 for one year; (*n*) Mary Birrell Davies Memorial Fund Scholarship, of the value of £60, tenable for four years, offered for competition in alternate years; open only to women students who will have attained the age of 19 on the first day of October next following the award; (*o*) Rankin Exhibition in Practical Anatomy, of £25, for one year; (*p*) Lady Jones Research Fellowship in Orthopædic Surgery, £200; (*q*) Samuels Memorial Scholarships, three at £20; (*r*) Ridgway Research Scholarship (£100); numerous prizes and medals.

The Medical School.—All the laboratories and classrooms are situated close together, communicating with one another, and are made up of four large blocks of buildings which form one side of the College quadrangle. There are the Johnston Laboratories for Experimental Medicine and Biochemistry; the Medical School for Anatomy, Surgery, Toxicology, and Ophthalmology; and the Thompson-Yates Laboratories for Physiology and Pathology. There is also a separate building for Tropical Medicine. Medical research has also been endowed with several new laboratories in which students can pursue research work after graduation.

Clinical Studies.—The Clinical School of the University consists of four general hospitals—the ROYAL INFIRMARY, the DAVID LEWIS NORTHERN HOSPITAL, the ROYAL SOUTHERN HOSPITAL, and the STANLEY HOSPITAL; and of five special hospitals—the Eye and Ear Infirmary, the Hospital for Women (with the Samaritan Hospital), Liverpool Maternity Hospital, the Royal Liverpool Children's Hospital, and St. Paul's Eye Hospital. These hospitals contain in all a total of about 1500 beds. The organisation of these hospitals to form one teaching institution provides the medical student and the medical practitioner with a field for clinical education and study which is unrivalled in extent in the United Kingdom. All the hospitals are within easy access of the University. There are a large number of appointments to house physicianships and surgeonships both at the general and special hospitals which are open to qualified students of the school.

Public Health Department.—This is located in a separate building, in which full courses of instruction are given to students for the Diplomas and Degrees of the University and of other Examining Boards.

Prospectuses and further information may be had on application to the Dean of the Faculty of Medicine, University of Liverpool.

UNIVERSITY OF MANCHESTER.

Four degrees in Medicine and Surgery are conferred by the Victoria University of Manchester—viz., Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). A Diploma in Psychological Medicine, a Diploma in Public Health, and a Diploma in Bacteriology are awarded by examination to registered medical practitioners.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Before admission to the degree of M.B. or Ch.B. candidates are required to present certificates that they will have attained the age of 21 years on the day of graduation, and that they have pursued the courses of study required by the University Regulations during a period of not less than five and a half years subsequently to the date of their registration by the General Medical Council, two of such years having been passed in the University subsequent to the date of passing the first M.B. Examination.

The First Examination: (1) Chemistry and Physics (2) (*a*) Botany, (*b*) Zoology. Candidates must hav attended, during at least six months, courses both lectures and of laboratory work in each of the abov named subjects. The Examination is divided in two parts: Part 1, Inorganic and Elementary Organ Chemistry and Physics; Part 2, (*a*) Botany, (Zoology. The candidates sit for these par separately. The Second Examination: (1) Anaton and Histology; (2) Physiology, including Physi logical Chemistry. Both parts must be pass simultaneously. The Third Examination: (1) Pha macology and Materia Medica; (2) Pathology a Bacteriology. The Final Examination: (1) Medicin Systematic and Clinical (including Mental Diseases a Diseases of Children); (2) Surgery, Systemat Clinical, and Practical; (3) Obstetrics and Gynæcolo (including Clinical and Practical); (4) Foren Medicine; (5) Hygiene and Preventive Medicir The Final Examination is divided into two part Part I., Forensic Medicine, Hygiene and Preventi Medicine; Part II., Medicine, Surgery, Obstetri and Gynæcology (Systematic, Clinical, and Ora The two parts of the Final Examination must ea be passed as a whole. Candidates for the Second Pa must have completed the sixth year of medical stud

Degree of Doctor of Medicine.—Candidates are n eligible for the degree of Doctor of Medicine unle they have previously obtained the degrees of Bachel of Medicine and Bachelor of Surgery and at lea one year has elapsed since they passed the examinati for those degrees. Candidates may elect either (1) present an original dissertation; or (2) to under an examination. The dissertation must embody t results of personal observation or original researc either in some department of medicine or of sor science directly relative to medicine. The examin tion, which will be written and practical, is in t Principles and Practice of Medicine, in Pathology, a in some other subject to be selected by the candida

Degree of Master of Surgery.—Candidates are n eligible for the degree of Master of Surgery unless th have previously obtained the degrees of Bachelor Medicine and Bachelor of Surgery and at least o year has elapsed since they passed the examinati for those degrees. The degree is conferred in t following branches: Surgery (Branch I.), Gynæcolo (Branch II.), Ophthalmology (Branch III.), Lary gology, Otology, and Rhinology (Branch IV.).

Degrees of B.Sc. and M.Sc.—The ordinary degr of B.Sc. in the Schools of Anatomy and Physiolo may be obtained by students in Medicine who in th third year of study for the degree of M.B., Ch.B., co plete the additional courses in these subjects prescrib for this degree. Candidates for the Honours degree B.Sc. in Anatomy or Physiology, who are students Medicine, are required to attend courses in advanc Anatomy and Physiology for four terms after passi the Second Examination for the degrees of M.B., Ch. Graduates in science may proceed to the degree of M.S by presentation of an approved thesis.

Diplomas: 1. The following are available f candidates holding a registrable qualification medicine, surgery, and midwifery; examinations a in two parts in each diploma and are written, o and practical. Candidates may present themsel for Parts I. and II. separately or at the same ti provided that no candidate be admitted to Part unless he has already passed in Part I. No candidat name will be published until he has satisfied t examiners in both parts of the examination:—

(*a*) *Diploma in Psychological Medicine.*—Pa time course: extending over three University term two of which must be spent at the University. S months' residence must be spent at a recognis Hospital for Mental Diseases.

(*b*) *Diploma in Public Health.*—The cou extends over twelve calendar months at leas Part I. of the examination is held in June a October, and Part II. in March and Octob

Instruction for at least one of the parts must be taken out at the University. Holders of the Diploma in Public Health are eligible for examination for the Certificates in School Hygiene and Factory Hygiene after attending the prescribed periods of study and hospital practice.

2. *In Veterinary State Medicine.*—Length of course, three University terms. Candidates must be members of the Royal College of Veterinary Surgeons.

3. *In Bacteriology.*—For candidates who have graduated either in science or medicine, or obtained other approved qualification. Length of course, one academic year. A satisfactory thesis on an approved subject must be presented.

Scholarships, Fellowships, and Prizes.—The following are offered in connexion with medical study at the Victoria University:—Scholarships: Dreschfeld Entrance (triennial), £20; John Russell Medical Entrance, £45; Sam Gamble Entrance for Women; Graduate Entrance (fees up to 160 guineas); two Dauntesey Medical Junior, £50 each; Dauntesey Medical Senior, £50; Professor Tom Jones Exhibition in Anatomy, £25; Dickenson Trust Scholarships in Anatomy and Pathology; Platt Physiological, £90; Graduate Research Scholarship, £70; Dickenson Trust Travelling Scholarships in Medicine and Surgery; Ashby Memorial in Diseases of Children (triennial), £100; Holt Post-Graduate Medical Scholarship for Women, £60; Fellowships: Leech Research, £70; Professor Tom Jones, Surgical, £105; Morrison Watson in Anatomy, £150; John Henry Agnew in Diseases of Children, £120; Delépine in Preventive Medicine (biennial), £300; Worswick (Causes and Treatment of Rheumatoid Arthritis), £300; Zimmern Travelling Fellowship for Men, £175, also for Women; Honorary Research Fellowships. Prizes: Sidney Renshaw in Physiology, £15; Wild Prize in Pharmacology, £10; Turner Medical, two prizes each of 10 guineas; Dumville Surgical, £15; Knight Prize in Psychological Medicine, £50; John Henry Agnew in Diseases of Children, £30. There are many general entrance scholarships, in addition to those already mentioned, open for competition, the examinations for which are held in the month of May. Full particulars can be obtained from the Registrar.

The Medical School.—This school, largely extended in 1920, is provided with dissecting-rooms, X ray rooms physiological laboratories, private laboratories, and work-rooms, besides lecture-rooms, museums, and general and departmental libraries. A special laboratory is equipped for experimental work on the central nervous system. In the pathological laboratories (now removed to special buildings close to the Royal Infirmary) ample provision is made for the teaching of pathology and bacteriology and for the prosecution of original research. The Helen Swindells Laboratory is specially equipped as part of a new department for investigation in cancer. Ample facilities for investigation are are provided in Anatomy, Physiology, and Materia Medica; new Pharmacological Laboratories were added last year. In the public health department, which is lodged in a separate institute in York Place, near the Royal Infirmary, suitable laboratory accommodation is provided for the study of sanitary chemistry, physics, and practical bacteriology in the departments of chemistry and physics and in that of pathology.

Clinical Studies.—The clinical and practical departments of medical study are taught partly in the Medical School and partly in the Royal Infirmary and St. Mary's Hospitals for Women and Children, a fever hospital, mental hospitals, a convalescent home, and other special hospitals. Medical and Surgical Clinical Classes are conducted in the Infirmary, and separate instruction is afforded in the elements of Medical and Surgical Physical Diagnosis, in Obstetric Medicine, Ophthalmic Surgery, and Pathological Anatomy by the different members of the staff of the Medical School and Infirmary.

Post-graduate Studies.—Post-graduate Courses in the following subjects have been arranged for during 1930–31, in addition to those usually held at the various hospitals: 1. Whole-time intensive course in Obstetrics. 2. A Post-graduate Day. 3. Part-time courses in (i.) Diseases of the Eye, (ii.) Diseases of the Skin, (iii.) Practical Instruction in Local Anæsthesia and Minor Surgery, (iv.) Bacteriology and Immunity. 4. Clinical Assistantships. Syllabuses and other information may be obtained on application to the Dean of the Medical School, Manchester University.

Manchester Royal Infirmary.

The Manchester Royal Infirmary is built on the pavilion system, near the University, and has accommodation for 614 patients (including 54 beds at the Central Branch). The medical side consists of four units, each unit having a testing-room for the scientific investigation of morbid products and a class-room. The surgical beds are arranged in five units, each unit having its own operation theatre, with anæsthetising, recovery, sterilising, testing and apparatus rooms, and its own class-room attached. All of these units are occupied. The gynæcological, aural, and out-patient departments each have their own operating theatre. Bacteriological investigations are carried out in a special clinical laboratory. A department for the study of heart disease, with an electric cardiograph and other instruments for research, diagnosis and teaching purposes is attached to the medical wards. There is also a laboratory for clinical research. In the educational block is a large lecture theatre and a museum. In the same building is housed the X ray department, which has nine separate X ray outfits for different purposes, and in which one large room is put aside specially for X ray demonstrations and teaching purposes. A large massage school is also connected with this department.

Associated with the Infirmary are: (1) the Convalescent Hospital at Cheadle, containing 132 beds; and (2) the Central Branch in the City, which has now accommodation for 54 patients. The Associated Hospitals thus contain 800 beds and are under the same management. Women students are admitted on the same terms as men.

Two Entrance Scholarships in Medicine of the value of £160 each are offered annually by the Council of the Manchester University and the Medical Board of the Manchester Royal Infirmary for proficiency in Arts and Science subjects respectively. Other scholarships and prizes are mentioned in the College syllabus. Numerous annual appointments and junior appointments may be held by those who have attended the practice of the Infirmary.

Royal Manchester Children's Hospital.

The hospital, which is situated at Pendlebury, Gartside-street, Manchester, contains 190 beds and 30 in the Convalescent Home, Lytham St. Anne's. The medical staff visit the hospital daily at 10 A.M. Clinical instruction is given by the medical staff at the Hospital and Dispensary. There is a new Massage and Electrotherapeutic Department, also an Artificial Sunlight Department. Clinical Assistants are appointed for periods of six months. In throwing open these appointments to qualified medical men and women, the Board is actuated by the desire to aid those qualified medical men and women who wish to have opportunities for the further study of disease in children, or who wish to fit themselves for posts as Medical Officers to Children's Hospitals, to Child Welfare Centres, or for School Medical Officer appointments. There is an Orthopædic Department. Out-patients' day is on Tuesday at Gartside-street, and a ward at Pendlebury is devoted to cases needing operative treatment. Out-patients are seen daily at 9 A.M. at the Out-patient Department, Gartside-street, Manchester. Secretary: Mr. W. M. Humphry.

Ancoats Hospital, Manchester.

There are 114 beds with a Convalescent Branch of 35 beds at Great Warford, Alderley Edge, Cheshire. The hospital, founded in 1828, will be extended during the next two years by the addition of a new ward

block, an operating theatre block, pathological department, physiotherapeutic department, and lecture theatre.

The medical division consists of three units served by consultative out-patient clinics. One unit includes a cardiological department; another devotes special attention to gastro-enterology; and the third to neurology. The surgical division comprises an orthopædic unit in which all the fractures and injuries of the hospital are treated; a unit devoted particularly to urology; a unit devoted to abdominal surgery; and an oto-laryngological unit. All units include out-patient clinics. A special clinic staffed by a team consisting of surgeons, pathologist, radiologist, and consultant in radium therapy has recently been created for the study and treatment of malignant disease. The demand on the surgical in-patient accommodation is great, 800 patients at the present time being on the waiting-list. Clinical teaching is given both to undergraduate and post-graduate students in all out-patient clinics, in the wards, and in the form of special lectures. The under-graduate teaching includes a University course in Orthopædic Surgery given in the Michaelmas term, and demonstrations on the examination of the ear, nose and throat. The hospital takes an important share in the University of Manchester Post-graduate scheme. A post-graduate "day," open to all practitioners without fee, is held on each Thursday in the University terms. Special intensive post-graduate courses are held from time to time. Applications for entry to these courses should be made to the Dean of the Faculty of Medicine, University of Manchester.

There are six residents: a resident surgical officer, a resident medical officer, three house surgeons, and one house physician. These appointments are open both to men and women graduates, and are recognised by the University of London for the purposes of the M.D. and M.S. degrees. There are also four registrar appointments (part time); medical, orthopædic, surgical, and pathological. These are made annually, and are renewable up to a period of three years. General Supt. and Secretary: Herbert J. Dafforne.

Manchester Northern Hospital for Women and Children.

The hospital, situated at Park-place, Cheetham Hill-road, Manchester, contains 73 beds. Out-patients are seen daily from 8.30 to 10 A.M.

UNIVERSITY OF LEEDS.

Four degrees in Medicine and Surgery are conferred—viz.: Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), also Degrees and Diplomas in Dental Surgery and Diplomas in Public Health and in Psychological Medicine. Courses and Degrees in the Faculty are open to men and women alike.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Candidates for these degrees are required to present certificates showing that they will have attained the age of 21 years on the day of graduation, and have attended courses approved by the University extending over not less than five years, two of such years at least having been passed in the University, one of which must be subsequent to the date of passing the First Examination. Candidates must also satisfy the examiners in the several subjects of the following examinations, entitled respectively: the Matriculation Examination, or such other examination as may have been recognised by the Joint Matriculation Board in its stead; the First Examination; the Second Examination; and the Final Examination. The First Examination consists of: Part I., Physics and Inorganic Chemistry; Part II., Zoology and Botany; Part III., Organic Chemistry. Candidates will be allowed to pass the parts separately. The Second Examination consists of: Part I., Materia Medica and Practical Pharmacy; Part II., Anatomy Physiology. Candidates will be allowed to pass either part separately. The Final Examination consists of: Part I., Pharmacology, Pathology and Bacteriology; Part II., Medicine, Surgery, Obstetrics, Gynæcology, and Clinical Pathology; Part III., Forensic Medicine, Public Health, and Therapeutics. Part I. may be taken at the end of the second clinical year, and Parts II. and III. may be taken at the end of the third clinical year, but not before the completion of the fifth year of medical study. If taken separately Part II. may be passed before Part III.

Degree of Doctor of Medicine and Master of Surgery.—Candidates are not eligible for the degree of Doctor of Medicine or Master of Surgery unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery of the University (or of Victoria prior to December, 1904) and at least two years' Hospital Practice or four years' other professional practice for the former, and one year has elapsed for the latter since they passed the examination for those degrees. Candidates for the degree of Doctor of Medicine may present a dissertation and, if the dissertation is considered to be of exceptional merit, will not be required to pass an examination. The first term commences on Oct. 1st. Prospectus can be obtained from the Academic Sub-Dean.

Post-graduate work.—Practitioners wishing to attend Infirmary practice during short periods, or post-graduate classes held by members of the clinical staff, may do so on application to the Clinical Sub-Dean, from whom particulars may be obtained.

Clinical Studies.—The clinical studies are pursued mainly at the LEEDS GENERAL INFIRMARY, which has accommodation for 630 in-patients, including 88 beds at branch hospitals in the country. Clinical teaching takes place daily in the wards, and Clinical lectures are given in Medicine and Surgery by the Physicians and Surgeons. There are Medical, Surgical, Ophthalmic, Aural, Electrotherapeutic, and Radiographic Departments, in each of which special instruction is imparted to students. Gynæcological and Children's Departments, together with Laryngeal, Venereal, and Skin Clinics, are in operation, and there is a special ward for cases of nutritional disorders of children. Several valuable prizes are given at the end of each session. Numerous appointments at the Infirmary are annually open to students after qualification. Further particulars concerning these, and the scholarships and prizes open to competition, may be obtained from the Dean of the Faculty of Medicine.

In addition to work in the General Infirmary, clinical instruction in obstetrics is given in the Leeds Maternity Hospital and in mental and infectious diseases in the Wakefield (W.R.) Mental Hospital and Leeds City Fever Hospital respectively.

UNIVERSITY OF SHEFFIELD.

The Degrees in the Faculty of Medicine are Bachelor of Medicine and Bachelor of Surgery (M.B., Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.), Bachelor of Dental Surgery (B.D.S.), and Master of Dental Surgery (M.D.S.). There is also a Diploma of Licentiate in Dental Surgery. The courses and degrees in the Faculty of Medicine are open to men and women alike. Candidates must matriculate in the University or pass such other examination as may be recognised for this purpose by the University and sanctioned by the Joint Matriculation Board, and must pass also the further examination in Chemistry and Physics.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—A candidate must have attained the age of 22 years on the day of graduation, and have pursued the courses of study required by the University regulations during a period of not less than five and a half years subsequently to the date of his matriculation, three of such years at least having been passed in the Faculty of Medicine of the University one at least being subsequent to the passing of the Second Examination. The subjects of the First Examination are Chemistry, Physics and Biology. Candidates who have passed the Intermediate

Examination in the Faculty of Pure Science, including any or all of the subjects of the First Examination, will be considered to have passed the latter examination when they have passed in such of its subjects as they did not take for the Intermediate B.Sc. Examination. Such candidates shall be required to pay the fee for the First Examination. Candidates must, after matriculation, pass a preliminary examination in Physics and Chemistry before taking the First Examination, for which they must have attended courses of instruction (lectures and laboratory work) in Chemistry, Physics, and Biology for one year each. The Second Examination: Candidates must have attended courses of instruction in Physiology (first part) for one year, and in Anatomy for five terms. The Third Examination: Candidates must have attended courses of instruction in Pathology for five terms in Pharmacology for four terms (and one term in Pharmacy), in Applied Anatomy for four terms, and in Physiology (second part), for six terms. The Final Examination: The subjects are, Part I., Forensic Medicine and Public Health. Candidates must have attended courses for one term in each subject; Part II., Medicine (including Mental Diseases, Diseases of Children, and Vaccination), Special Pathology (including Morbid Anatomy and Clinical Pathology), and Therapeutics; Part III., Surgery (including the administration of Anæsthetics, Diseases of the Ear, Nose and Throat, Ophthalmology, and Surgical Pathology), and Obstetrics and Gynæcology, including Antenatal and Postnatal practice and Infant Hygiene. Candidates for Parts II. and III., must have completed a minimum of five and a half years of approved study.

Degree of Doctor of Medicine.—Candidates for the degree of Doctor of Medicine must have passed the examination for the degrees of M.B., Ch.B. at least three years previously, must present a thesis embodying observations in some subject approved by the professor of medicine, and must pass an examination in the Principles and Practice of Medicine.

Degree of Master of Surgery.—Candidates must have taken the M.B., Ch.B. at least three years previously, and must since have held for not less than twelve months a surgical appointment in a public hospital. The subjects of examination are Systematic, Clinical, and Operative Surgery, Surgical Anatomy, Surgical Pathology and Bacteriology.

Scholarships and Prizes.—The following scholarships are offered: Four Town Trustees scholarships offered annually, each of the value of £50 per annum for three years. Medical: offered annually, covers cost of degree course in the Faculty of Medicine. Six Edgar Allen, offered annually, each of the value of £125 per annum for three years. Post-graduate: Frederick Clifford scholarship, value £50 per annum, tenable for two years. Mechanics' Institute scholarship, value £50 for one year with free admission to those University courses taken by the holder in connexion with his work, renewable for a second year. Town Trustees Fellowship, value £75 for one year. Medals and Prizes: Kaye scholarship; Gold Medal in Clinical Medicine and Surgery; John Hall Gold Medal in Pathology; Holroyd Gold Medal in Anæsthetics; the Walter S. Kay Gold Medal in Mental Diseases; bronze medals. Particulars of all the above may be obtained from the Registrar.

The Medical School.—The Medical Department occupies the entire north wing of the University quadrangle. The various athletic and other students' societies are under the management of the Union Representative Council, elected annually. There are large and comfortable common rooms both for men and women students, and two Students' Unions, one for men and one for women. A refectory is open daily at the University where students may obtain meals and refreshments at moderate prices. The University journal *The Arrows*, edited by a committee of staff and students, is published each term. The University Halls, "Oakholme," Clarkehouse-road; "Tapton Cliffe," Fulwood-road, and "Endcliffe University Hall," Endcliffe Vale-road, are recognised by the Senate as halls of residence for women students; full particulars may be obtained from the tutor for women students. Stephenson Hall is a hall of residence for men students particulars may be obtained from the Warden.

Clinical Studies.—The University is within easy reach of the various hospitals with which it is connected for clinical purposes.

The SHEFFIELD ROYAL INFIRMARY (500 beds) provides all the opportunities of a large general hospital with special departments for Skin and Ear. The SHEFFIELD ROYAL HOSPITAL, 340 beds, has special out-patient departments for Diseases of the Throat, Ear, Skin, Orthopædics, and Mental Diseases. The two institutions are amalgamated for the purposes of clinical practice, medical, surgical, and special. There are special departments for the treatment of Diseases of the Eye, with wards assigned to them, at both hospitals, and excellent junior appointments. The JESSOP HOSPITAL FOR DISEASES OF WOMEN, with 142 beds, has also a Maternity department, with about 900 in-patients per annum and about 3000 out-patient cases attended. The CHILDREN'S HOSPITAL has 92 beds. Special courses on Fevers are held at the CITY FEVER HOSPITALS (988 beds) and on Mental Diseases at the SOUTH YORKSHIRE MENTAL HOSPITAL (1900 beds). Every facility is afforded in the various laboratories for the prosecution of advanced studies and research.

Post-graduate Courses.—Post-graduate courses of clinical instruction are held annually in the various hospitals connected with the School.

UNIVERSITY OF BRISTOL.

In the Faculty of Medicine there are the following degrees:—Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), Bachelor of Dental Surgery (B.D.S.), and Master of Dental Surgery (M.D.S). There are also the following diplomas: Diploma in Public Health (D.P.H.), Diploma in Dental Surgery (L.D.S.), and Diploma in Veterinary State Medicine.

All candidates for degrees in Medicine, Surgery, and Dentistry are required to pass, at Matriculation standard, an examination called the School Certificate Examination, or to pass such examination as may be regarded as equivalent by the Senate. All courses, degrees, and diplomas are open to men and women.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Candidates shall be not less than 21 years of age and shall have pursued the courses prescribed by University Regulations during not less than five years after passing the first examination in Chemistry and Physics and entering on the professional curriculum at the University, or an institution recognised as equivalent, of which three shall have been passed in the University, and two of these three subsequent to passing the second examination. All candidates for the degrees of M.B., Ch.B., are required to satisfy the examiners in the several subjects of three examinations. The First Examination: The subjects of examination are: Chemistry (Inorganic), Physics, and Biology, the courses pursued being those for the time being approved for the intermediate part of the B.Sc. curriculum. This part of the curriculum shall extend over one year. (Candidates who have passed the Higher School Certificate approved by the Board of Education in these subjects will not be required to sit for the first examination and will be regarded as having completed one year of study.) The Second Examination: The subjects of examination are: Organic Chemistry and Elementary Anatomy (Part I.) and Advanced Anatomy and Physiology (Part II.). The Final Examination: The subjects of examination are: Materia Medica and Pharmacy, Pharmacology and Therapeutics, General Pathology, Morbid Anatomy, and Bacteriology (Part I.); Special Pathology, Forensic Medicine and Toxicology, Public Health, Obstetrics (including Diseases of Women),

Surgery (Systematic, Clinical, Practical, and Operative), Medicine (Systematic, Clinical, and Practical, including Mental Diseases) (Part II.). The subjects included in Part II. may be taken in two groups—viz., Group I., Surgery and Obstetrics; Group II., Medicine, Public Health, Special Pathology, Forensic Medicine and Toxicology. Candidates may pass Parts I. and II. together, or separately, and the two groups of Part II. may be taken together or separately. Forensic Medicine and Toxicology may be taken with Part I., or with Group II. of Part II.

Degree of Doctor of Medicine.—Candidates shall be Bachelors of the University of not less than two years' standing as such and may elect either (1) to pass an examination in General Medicine, or (2) to pass an examination in State Medicine, or (3) to present a Dissertation. The candidate who elects to pass the examination in State Medicine must hold a diploma in Public Health of some University or College, and the candidate who elects to present a Dissertation may be examined in the subject thereof.

Degree of Master of Surgery.—The degree may be taken in General Surgery or in Special Subjects. Candidates shall be Bachelors of not less than two years' standing as such. For General Surgery, they shall pass an examination in Surgical Anatomy, Pathology and Bacteriology, and in Operative, Clinical and General Surgery, and shall present a dissertation. For Special Subjects—i.e., Ophthalmology or Oto-rhino-laryngology or Gynæcology, they shall, in addition to having studied and practised for two years the subject concerned, have held an approved appointment in it for not less than six months; they shall pass a written, oral and clinical examination in the branch of Surgery concerned, as well as in the Anatomy, Physiology and Pathology of the region of the body concerned (including in the case of Ophthalmology Physiological optics) and also a written examination in the principles of General Surgery.

Clinical Studies.—The allied hospitals (BRISTOL ROYAL INFIRMARY and BRISTOL GENERAL HOSPITAL) have between them about 600 beds and extensive out-patient departments, special clinics for Diseases of Women and Children and those of the Eye, Throat and Ear, in addition to large and well-equipped departments for Dental work and large outdoor Maternity Departments.

At each of these institutions there are well-arranged pathological museums, post-mortem rooms, and laboratories for Morbid Anatomy. There are also laboratories for work in Clinical Pathology, Bacteriology, and Cytology, in which special instruction is given in these subjects. Departments are provided and well equipped for X ray work, both for diagnosis and treatment, the various forms of Electrical treatment, including High-frequency Currents, Electric Baths, Finsen Light treatment, and Massage.

The students of the school also attend the practice of the Royal Hospital for Sick Children and Women, containing 140 beds, and that of the Bristol Eye Hospital with 40 beds; and the Southmead Hospital, with 556 beds, may be visited.

There are numerous salaried junior appointments for residents who are graduates.

Scholarships and Prizes.—The following are awarded: The Ashworth Hallett Scholarship, value £40, open to women only; two Martin Memorial Pathological Scholarships of £10 each; the Tibbits Memorial Prize, value 7 guineas, for proficiency in practical surgery; the Committee's Gold and Silver Medals for fifth-year students for general proficiency; the Augustin Prichard Prize, value about 6 guineas, for proficiency in anatomy; the Henry Clark Prize, value 11 guineas, for proficiency in gynæcology; the Crosby Leonard Prize, value 6 guineas, for proficiency in surgery; the Suple Surgical Prize, a gold medal and 7 guineas; the Suple Medical Prize, a gold medal and 7 guineas; the Henry Marshall Prize, value £12, for dressers; the H. M. Clarke Scholarship, value £15, for proficiency in surgery; the Sanders Scholarship, value £22 10*s.*, for general proficiency; the Barrett-Roué Scholarship for proficiency in disease of the eye, ear, nose, and throat, value £17; Lady Haberfield Scholarship, value about 25 guineas.

Bristol City Senior Scholarships and those offered by the Counties of Gloucestershire, Somerset, Wilts and Dorset, and the City of Bath are tenable in the University. The Beaverbrook Fellowship and some of the Fellowships awarded by the Colston Research Society for research in the University are allotted to the Faculty of Medicine.

Post-graduate Study.—Qualified medical practitioners may be appointed as clinical assistants for a period of one or more months. They may act as assistants, if times permit, in more than one department and in any of the hospitals during their period of study. They will be entitled to the use of the clinical laboratories and medical library, and have the right to attend in all departments, including operations, post-graduate and ordinary clinical demonstrations, and post-mortem examinations. Demonstration courses with weekly lectures are held from October to June inclusive.

All inquiries and applications for admission should be addressed to the Director of Post-graduate Studies (Clinical Section), Pathological Department, University of Bristol, who can be seen on any day by appointment.

Further information as to scholarships, curricula and fees can be obtained from the Dean of the Faculty of Medicine or the Registrar of the University.

UNIVERSITY OF WALES.

The University grants Degrees in Medicine, and Diplomas in Public Health and Tuberculous Disease. Preliminary courses of study for the Degrees in Medicine may be pursued at any of the constituent Colleges of the University—viz., at Aberystwyth, Bangor, Cardiff, or Swansea. The Welsh National School of Medicine is situated in Cardiff and is an integral part of the University College of South Wales and Monmouthshire there. All classes are open to both men and women students.

Particulars may be obtained on application to the Registrar of the University of Wales, University Registry, Cathays Park, Cardiff, or the Dean of the Faculty of Medicine, or to the Secretary, Welsh National School of Medicine, Newport-road, Cardiff.

ENGLISH MEDICAL CORPORATIONS GRANTING DIPLOMAS.

CONJOINT EXAMINING BOARD.

Under this heading we give the regulations for the examinations enjoined by the Conjoint Examining Board of the Royal Colleges of Physicians of London and Surgeons of England, and of the Society of Apothecaries upon students desiring their respective diplomas of qualification. We do not give any list of schools recognised by these bodies as eligible to prepare students for their examinations beyond mentioning that all the schools which we have already described (under the heading of the Universities to which they are attached) are recognised as suitable places of instruction by the corporations granting medical diplomas. The courses of study at the principal colonial medical schools are also recognised as qualifying for the examinations of these corporations.

Students are required to pass a Preliminary Examination in General Education recognised by the Board and a *Pre-Medical Examination* in Chemistry, Physics and Elementary Biology conducted by the Conjoint Examining Board before commencing the five years' curriculum of professional study or some other examination recognised by the Board—namely, the examination in Chemistry, Physics, and Biology for the degree in Medicine of any University recognised by the

Board; a Pre-Medical Examination conducted by any of the Qualifying Bodies whose Degrees or Diplomas are registrable on the Medical Register; the Higher School Certificates of Oxford and Cambridge Universities, and the Oxford and Cambridge Schools Examination Board; the Higher Certificates of London, Bristol, Durham Universities, the Joint Matriculation Board of the Northern Universities, and the Central Welsh Board Higher Certificate. A candidate must enter for Chemistry and Physics together, and he will not be allowed to pass in one without obtaining at the same time at least half the number of marks required to pass in the other subject. Not more than two terms of professional study (Anatomy and Physiology) will be recognised before Elementary Biology is passed. He will be admitted to the examination on producing evidence of having passed the required preliminary Examination in General Education. The examination is partly written, partly oral, and partly practical. A candidate rejected in one or both subjects of the examination will not be admitted to re-examination until after the lapse of a period of not less than three months. The fee for the examination is £3 3*s*., for re-examination in Chemistry £2 2*s*., and re-examination in Physics £1 1*s*.

There are two Professional examinations called the *First* and *Final Examinations*. The courses of study for these examinations may be commenced before the Pre-Medical examination in Chemistry and Physics or some equivalent examination has been passed, provided that three terms of study are completed after the examination has been passed.

The subjects of the First Professional Examination are: Section I. (*a*) Anatomy, including Histology and Embryology. (*b*) Physiology, including Biochemistry. Section II. Pharmacology and Materia Medica. A candidate must have attended at a recognised Medical School courses of instruction in Anatomy, including Embryology, during five terms, during which he must have dissected the whole body, courses of instruction in Physiology, including General Biology, Biochemistry and Biophysics during five terms, courses of instruction in Pharmacology, and Materia Medica. A candidate may present himself for the two Sections together or separately, but he must take parts (*a*) and (*b*) of Section I. together until he has passed in one or both parts, but a candidate will not be allowed to pass in one part unless he obtains at the same time at least half the number of marks required to pass in the other part.

Section II. of the examination may be passed at any time before the candidate enters for the Final Professional Examination. The fee for the First Professional Examination is £10 10*s*., for re-examination after rejection in Section I. £6 6*s*., for re-examination after rejection in either part of Section I. £3 3*s*., for re-examination after rejection in Section II. £3 3*s*. A candidate who produces satisfactory evidence of having passed an examination in the subjects of Section I. or of either part of Section I. and of Section II. in the examination for the degree in Medicine conducted at a University recognised by the Board will be exempted from further examination in such subjects.

Final Professional Examination.—The subjects of the Final Professional Examination are: Section I. Pathology (including Morbid Anatomy, Morbid Histology, and Clinical Pathology), and Bacteriology. Section II. Part I. Medicine, including Medical Anatomy, Forensic Medicine and Public Health. Part II. Surgery, including Surgical Anatomy and the use of Surgical Appliances. Part III. Midwifery and Gynæcology. The examination is partly written, partly practical, partly clinical, and partly oral. A candidate may take Sections I. and II. and the three parts of Section II. of the Final Examination separately or may take the whole examination together. He will be required to produce the certificates required by the regulations before being admitted to the respective parts of the examination. The fee for admission to Section I. is £4 4*s*.; for admission to section II., Part I., £10 10*s*.; Part II., £10 10*s*.; Part III., £6 6*s*.; and the re-examination fees are respectively £3 3*s*., £6 6*s*., £6 6*s*., and £4 4*s*. Members of recognised universities outside the British Possessions are admissible to the examinations of the diplomas of L.R.C.P. and M.R.C.S., under special conditions. Graduates in medicine and surgery are required to pass the first examination and to complete 12 months hospital practice before admission to any part of the final examination. Undergraduates are required to complete the full curriculum of 33 months for the final examination after having passed the first examination. For further information see the current regulations of the Conjoint Examination Board of England.

Members of certain recognised Indian, Colonial, and Foreign universities who have passed examinations for the Degree of Doctor or Bachelor of Medicine or Surgery in the subjects of the First Examination may present themselves for the Final Examination under special conditions. The Board also grants Diplomas in Public Health, in Psychological Medicine, in Ophthalmic Medicine and Surgery, in Tropical Medicine and Hygiene, in Laryngology and Otology, and in Gynæcology and Obstetrics. Candidates must hold a Medical qualification registrable in the United Kingdom or be Graduates in Medicine of a recognised Indian, Colonial, or Foreign University. Particulars and conditions of admission to all examinations, fees, &c., may be obtained from the Secretary of the Examining Board, Examination Hall, Queen-square, London, W.C.1.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

THE MEMBERSHIP AND FELLOWSHIP.

The College confers two separate diplomas—the *Fellowship*, a purely honorary distinction, and the *Membership*, obtained by examination.

Membership.—The age for admission to this diploma, it will be noticed, has been changed from 25 to 23 years. The alteration in the by-law of the College is designed to enable men who have just finished house appointments to sit for an examination for which their recent clinical experience has exactly fitted them. The candidate must either have obtained the licence of the College, or a degree of Doctor or Bachelor of Medicine at a University which is registrable by the General Medical Council and is recognised by the Censors Board. The examination is directed partly to pathology and partly to the practice of medicine. Credit is also given to candidates who show a knowledge of Latin, Greek, French, or German. Further information may be obtained from the Registrar at the College. The fee for admission as a Member of the College is 40 guineas, except when the candidate for membership is a licentiate of the College, in which case the fee already paid for the licence is deducted from the 40 guineas. The fee for the examination is 10 guineas, which is reckoned as part of the fee for admission in the case of success.

Fellowship.—Fellows are selected annually from the ranks of Members by the Council of the College.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE FELLOWSHIP.

The Royal College of Surgeons of England confers its diploma of Fellow upon a few distinguished persons in an honorary capacity. Two Members of long standing may also be elected to the Fellowship annually. But the bulk of the Fellows obtain the diploma as the result of examination.

Fellowship.—The examination for the Fellowship is divided into two parts—viz., the First Examination and the Second Examination. The subjects of the First Examination are Anatomy and Physiology and those of the Second Examination are Surgery, including

Surgical Anatomy and Pathology. The examinations are partly written and partly vivâ voce, and include the examination of patients and the performance of operations on the dead body. The First Examination is held in June and December and the Second Examination in May and November.

The fees for examination are: First Examination, first admission 8 guineas, and for each readmission 5 guineas. Second Examination, each admission 12 guineas. The fee payable on admission to the Fellowship by Members is 10 guineas and by non-Members 30 guineas, in addition to examination fees.

A Member of the College is admissible to the First Examination at any time after receiving his Diploma of Membership. A candidate who is not a Member is admissible after passing the First Professional Examinations of the English Conjoint Board in Anatomy and Physiology, or the equivalent examination in his University, on the production of certificates of attendance upon prescribed courses.

A Member of the College is admissible to the Second Examination at any time after having passed the First Examination on producing evidence of having been engaged not less than six years in the study (or study and practice) of the profession.

A candidate who is not a Member of the College must possess the registrable surgical and medical degrees of universities recognised by the Council and must have been engaged in the study (or study and practice) of the profession for not less than four years subsequent to the date of obtaining the recognised qualification, one year of which shall have been spent in attendance on the Surgical Practice of a recognised hospital. The diploma of Fellow is not conferred upon successful candidates until they have attained the age of 25 years.

The Regulations may be obtained on application to the Director of Examinations, Examination Hall, Queen-square, London, W.C.1.

SOCIETY OF APOTHECARIES OF LONDON.

The Pre-Medical and Primary examination is held quarterly. Part I. includes Chemistry, Chemical Physics; Practical Chemistry; Materia Medica and Pharmacy. Part II. includes Anatomy, Physiology, and Histology. This examination cannot be passed before the completion of twelve months' Practical Anatomy with Demonstrations, and these subjects cannot be taken separately except in the event of the candidate having previously passed in one.

The Final examination is held monthly except in September. Part I. Clinical Surgery: Principles and Practice of Surgery, Surgical Pathology, and Surgical Anatomy, Operative Manipulation, Instruments, and Appliances. Part II. Clinical Medicine: Medicine, Pharmacology, Pathology, and Morbid Histology; Forensic Medicine, Hygiene, Theory and Practice of Vaccination; and Mental Diseases. Part III. includes Midwifery, Gynæcology, and Diseases of New-born Children and the Use of Obstetric Instruments.

The course of study for the *Final examination* includes attendance on the Surgical and Medical Practice, with Post-mortem Examinations, at a hospital connected with a medical school for a period of three winter and three summer sessions, including a course of Practical Midwifery, with attendance on 20 Midwifery cases. The course of medical study must extend over five years, and the office of dresser or clinical clerk must be held at a hospital or other institution recognised by the Society. Three academic years (33 months) must elapse after a candidate has passed the examination in Anatomy and Physiology before he can complete the Final examination.

Evidence shall also be given of practical instruction in Infectious Diseases and in Mental Diseases (at a lunatic asylum or in the wards of an institution containing a special ward set apart for the treatment of mental diseases), and in any two of the following subjects: Ophthalmic Surgery, Laryngology with Rhinology and Otology, Dermatology, and Diseases of Children. Candidates intending to present themselves for examination are required to give 14 days' notice. The fee for the Licence is 20 guineas. Female candidates are admitted to examinations.

Master of Midwifery—This diploma has now been instituted and the examinations are held in May and November. Candidates will be admitted to the examination who have been registered practitioners for at least one year and who have held a resident appointment in an institution recognised by the Society for six months or more, and who for three months have attended an antenatal clinic and an infant welfare centre, also recognised by the Society. Until 1932 practitioners of ten years' standing may enter for the examination without further formality than the production of satisfactory evidence that they have made a special study of the subjects. The examination will be conducted by written papers and by clinical and oral tests.

The entrance fee for the examination is £10 10*s.* and a further fee, which at present is fixed at £10 10*s.*, will be paid before their admission to the Mastery, by those who have satisfied the examiners. Candidates for the examination must send in their certificates to the Registrar, who will supply any other information.

The examination offices are open from 10 A.M. to 5 P.M.; on Saturdays from 10 A.M. to 1 P.M. All letters should be addressed to the Registrar, Society of Apothecaries of London, Blackfriars, E.C.4.

METROPOLITAN CENTRES AFFORDING POST-GRADUATE FACILITIES.

Certain organisations and institutions provide for the needs of the medical student in his curriculum and for the post-graduate student requiring special forms of instruction and opportunities for clinical observation. Many of the institutions are recognised by the English Conjoint Examining Board as a place of study for the fifth year of the curriculum.

Special Diplomas in public health, tropical, psychological, and ophthalmic medicine, medical radiology and electrology, laryngology, otology, and tuberculosis are now granted in proof of intensive work along the different lines indicated. Of these the Diploma in Public Health, being regulated by the General Medical Council, is registrable. Appointments to and promotion in the various Services are largely dependent on the possession of a particular diploma, and each syllabus of the special courses available at the institutions which follow, either with or without association with the Fellowship of Medicine, is planned to afford the necessary instruction.

The Special Diplomas are dealt with fully on p. 495, where the Bethlem Royal Hospital, the Maudsley Hospital, and the Diploma in Psychological Medicine are referred to. Similarly the Hospitals of the Metropolitan Asylums Board provide post-graduate as well as under-graduate facilities, while the hospitals of the Seamen's Hospital Society both supply the instruction necessary for the Diploma in Tropical Medicine and Hygiene, and coöperate in the activities of the Fellowship of Medicine and Post-Graduate Medical Association.

Infectious Hospitals of the London County Council

These hospitals, of which there are 18 in the metropolis and the near vicinity, were transferred on April 1st, 1930, to the Council from the Metropolitan Asylums Board, which ceased to exist on March 31st 1930, under the provisions of the Local Government Act, 1929. The Council holds classes of instruction in fevers at all the infectious hospitals at which ordinary medical students attend, but the only hospital to which a class of instruction for the diploma in public health is attached is the North-Eastern Hospital. This course of lectures and demonstrations (three months) on clinical practice and in hospital admin

stration is given at the North-Eastern Hospital, St. Ann's-road, Tottenham, N.15, by the medical superintendent, on Mondays and Wednesdays at 4.45 P.M., and alternate Saturdays at 11 A.M., beginning Wednesday, Oct. 1st. This course complies with the requirements of the revised D.P.H. regulations of the General Medical Council. Application for further information should be made to the Medical Officer of Health, London County Council, Public Health Department (Special Hospitals), Victoria Embankment, London, E.C.4.

Seamen's Hospital Society.

The Society possesses seven establishments: the Dreadnought Hospital at Greenwich, 250 beds; the Albert Dock Hospital, E.16, 53 beds; the Hospital for Tropical Diseases, Endsleigh-gardens, W.C.1, 75 beds; Tilbury Hospital, Tilbury Docks, Essex, 92 beds; Queen Alexandra Memorial Hospital, Marseilles, 60 beds; King George's Sanatorium for Sailors, Bramshott, Hants, 80 beds; and the Angas Home, Cudham, 36 beds. Total, 646 beds. It has also a Dispensary at Southampton, from which patients are transferred to the hospitals. Courses of operative surgery and surgical pathology are arranged by the London School of Clinical Medicine at the Dreadnought Hospital.

The clinical teaching of the London School of Hygiene and Tropical Medicine is given at the Society's Hospital for Tropical Diseases, Endsleigh-gardens, W.C.1.

The Fellowship of Medicine and Post-Graduate Medical Association.

Some 50 general and special London hospitals work in conjunction with this Association, which has its office at Room 28 in the House of the Royal Society of Medicine, 1, Wimpole-street, London, W. 1. Arrangements are made for courses in medicine and in surgery, occupying the whole or part of each day for periods of one to four weeks. Fees, £1 1*s.* to £7 7*s.* Special evening courses for the M.R.C.P. and F.R.C.S. (Final) Examinations are organised at intervals. Series of weekly (free) lectures (during the winter months) and clinical demonstrations in medicine and in surgery (except during August and September) are also arranged. Membership of the Fellowship is open to all qualified medical practitioners, the membership fee being 10*s.* per annum, which includes the subscription to the monthly *Post-Graduate Medical Journal*. The provisional list of Special Courses for 1931 is now available. Full information regarding the courses of study can be obtained from the Secretary.

GENERAL.

Royal Northern Group of Hospitals.

The Royal Northern Hospital, Holloway, London, N.7, is the main institution of the Royal Northern Group of Hospitals, which includes the Royal Chest Hospital, City-road, E.C., Grovelands Hospital (Recovery Branch), Southgate, and the Reckitt Convalescent Home, Clacton-on-Sea. The total number of beds in the group is 400. Besides the honorary staff there are six anæsthetists, three pathologists, resident medical officer, resident house physician, three resident house surgeons, two resident casualty officers, and one resident obstetric surgeon. The large rectangular and circular wards, each of which contains 25 beds, the children's ward for children under 5 years of age, the observation wards in the new Casualty Department, the two operation theatres, and out-patient department are designed with a view of offering the greatest facilities for clinical work. The Special Departments include the following: Fracture, genito-urinary and neurological, physico-therapeutic, pathological (under a director of clinical pathology), tuberculosis, venereal diseases, and X ray (recently remodelled). Patients are removed to the Recovery Branch by ambulance a few days after operation. Demonstrations are given daily in the wards and out-patient departments. Clinical assistants (qualified), clinical clerks, and pathological clerks are appointed in the general and special departments and may receive certificates at the end of their terms of office. A new maternity department has been opened, and the light department has been re-equipped. A complete hospital for paying patients is now in course of erection.

Weekly lectures by members of the hon. medical and surgical staff are free to all medical practitioners. Special classes and demonstrations are being arranged for post-graduates. They include instruction in general medicine and surgery, and also lectures and demonstrations in special subjects at the Royal Northern and Royal Chest Hospitals.

Prince of Wales's General Hospital.

This hospital, situated in Tottenham, is in the midst of a densely populated neighbourhood, and contains medical, surgical, gynæcological, and children's wards, having 200 beds. There are special departments for gynæcological cases, diseases of the eye, ear, throat, and nose, skin diseases, medical electricity, radiography, and dentistry. Operations are performed every afternoon of the week (except Saturday) at 2.30 P.M. Clinical instruction, ordinarily including laboratory classes, and lectures are given in the wards and out-patient departments, laboratories, and lecture hall in connexion with the North-East London Post-Graduate College attached. There are six resident medical officers, and clinical assistants are appointed under certain conditions. Special intensive post-graduate courses are also held at intervals throughout the year. Further particulars in regard to the hospital may be obtained from Dr. S. C. Shanks, Secretary to the Medical Committee, 87, Harley-street, W.1; or from Mr. T. H. C. Benians, F.R.C.S., Dean of the College, at the Hospital.

West London Hospital.

This hospital has 220 beds. Attached to the hospital is the West London Post-Graduate College. The practice of the hospital is reserved exclusively for qualified men. Instruction is given in the medical and surgical out-patient rooms and demonstrations are given in the wards. Clinical assistantships are obtainable in the various general and special out-patient departments. Special classes are held in the Diseases of the Throat and Nose, Skin, and Eye, and in Gynæcology, Medical Electricity, Operative Surgery, Bacteriology, Anæsthetics, Intestinal Surgery, Medical and Surgical Diseases of Children, Blood and Urine, Clinical Microscopy, Cystoscopy, Venereal Diseases, and Operative Ophthalmology, Radiography, X Ray Therapy. The accommodation for post-graduates consists of a lecture room, together with reading, writing, and class rooms. The hospital has a fully equipped pathological laboratory. The certificate of the hospital is accepted by the Admiralty, War Office, Colonial Office, and India Office in cases of study leave. Further information can be obtained on application to the Dean, Sir Henry Simson, at the Hospital, Hammersmith, W. Secretary of the Post-Graduate College, Mr. C. Cole, and of the Hospital Mr. H. A. Madge.

London Temperance Hospital.

The hospital (Hampstead-road, N.W.) contains 136 beds. The medical and surgical practice of the hospital is open to students and practitioners. Operations: Monday, 1.15 P.M., Tuesday, 2.30 P.M., Wednesday, 9 A.M. and 2 P.M., Thursday, 8 A.M., Friday, 10 A.M. and 3 P.M., and Saturday, 9 A.M. New Out-patient Departments for special diseases have been opened: Neurology, Diseases of the Stomach and Disorders of Digestion, Diseases of Women, Genito-urinary Diseases, Diseases of the Rectum, and Dermatology.

Hampstead General and North-West London Hospital.

In-patient Department: Haverstock Hill, N.W.; Out-patient Department: Bayham-street, Camden Town (138 beds—viz., 109 free, 8 isolation and

observation, &c., and 21 paying or contributory). Serves Hampstead and the populous districts of Kentish Town and Camden Town. The out-patients, with the exception of Hampstead casualty and emergency cases, attend exclusively at the Out-patients' Department, Bayham-street, Camden Town. Further particulars from the Secretary at the hospital. Post-graduate work is in connexion with the Fellowship of Medicine.

Queen Mary's Hospital.

This hospital has developed from the West Ham and Eastern General Hospital. It has 216 beds and ministers to a very poor public. Founded as a dispensary in 1861, and developing into a hospital in 1890, steady extensions have been made during this century. A Royal Charter was obtained in 1917, and the hospital has become a valuable charity with a full medical staff of physicians and surgeons, and specialists for gynæcology, obstetrics, ophthalmological surgery, radiology, and dental surgery. The Fellowship of Medicine and Post-Graduate Medical Association make frequent use of the opportunities here offered. A Radium Officer has recently been appointed as a supply of Radium has been sent to the Hospital by the King's Fund. The hospital has also appointed an Orthopædic Surgeon to set up a new Orthopædic Department, and in addition, a Dermatologist has been appointed to look after the new Skin Department. The number of beds has increased from 213 to 216 by virtue of the fact of the building and opening of a new Isolation Block for the Maternity Wing. Particulars may be obtained from Major Raphael Jackson, Secretary, Queen Mary's Hospital, Stratford, E.15.

NEUROLOGY.

National Hospital, Queen-square.

The hospital, with the Convalescent Home at East Finchley and branch at Clapham Park, contains 265 beds and cots. The out-patient physicians attend every Monday, Tuesday, Wednesday, Thursday, and Friday at 2 P.M., and the physicians daily. Clinical clerks are appointed under physicians and clinical assistants to out-patient physicians. Post-graduate Courses of Lectures and Demonstrations are held three times every year, usually commencing in January, May, and October, and lasting eight weeks. Special Courses in Neurological Ophthalmology, Neuropathology, and the Anatomy and Physiology of the Nervous System are given. The Pathological Laboratory is available for special work under the Pathologist.

West End Hospital for Nervous Diseases.

This institution is recognised by the University of London as a school of instruction in Neurology for the M.D. degree, Branch III., and for the D.P.M. The Out-patient Department is in Welbeck-street, W.; the In-patient Department is at Gloucester-gate, Regent's Park, and contains 80 beds. Completely equipped with pathological and other special departments, the hospital offers every facility for instruction in Neurological subjects. In conjunction with the Bethlem Royal Hospital, it offers courses of instruction for the D.P.M. Additional series of clinical demonstrations, apart from the general practice of the hospital, are held regularly each session, and the hospital coöperates with the Fellowship of Medicine in the programmes of special post-graduate teaching organised by the Association. Appointments as Hon. Clinical Assistants in the Out-patient Department are open to registered medical practitioners. The Savill Memorial Prize (value £15) and Medal are offered biennially for competition among post-graduate students who have attended the practice of the hospital or any special course. Full particulars may be obtained from Dr. C. C. Worster-Drought, Dean, or J. P. Wetenhall, Secretary, 73, Welbeck-street, W.

Hospital for Epilepsy and Paralysis.

This hospital in Maida Vale, W., contains 85 beds. Both in-patient and out-patient departments are open free to students as well as to medical graduates. The out-patient department is open every week-day except Saturday at 2 P.M.

HEART AND LUNGS.

Brompton Hospital for Consumption and Diseases of the Chest.

The hospital contains 350 beds. The recent provision of 25 (surgical) beds in a special block has increased the total number up to 350 (approximately). The sanatorium at Frimley contains 100 beds and 50 beds for paying patients. Six house physicians reside in the hospital for a term of six months; their duties include attendance in the out-patient department. An additional month may be spent at the Sanatorium. Pupils are admitted to the practice of the hospital. Clinical Demonstrations are given throughout the year by members of the medical staff. Clinical assistants are appointed to the physicians in the out-patient department and clinical clerks to the physicians in the wards. The medical practice of the hospital is recognised by the English Conjoint Board and also by the University of London, the Apothecaries' Society, and the Army and Navy and Indian Medical Boards. The hospital is open to post-graduates and students. The arrangements for post-graduate teaching have recently been revised and will now consist of special courses of one month's duration, to be held in the months of October, November, January, March, and June (fee for the month 4 guineas). Arrangements have also been made for undergraduates to work as clinical clerks in the wards and the out-patient department and to receive special instruction for one month (fee 2 guineas).

Mount Vernon Hospital.

The hospital contains 150 beds, Surgical. Clinical Demonstrations are given by the visiting Medical Staff at the hospital at Northwood. Clinical assistants are appointed to physicians in the wards. Diagnostic and follow-up departments, 14, Riding House-street, W.1.

City of London Hospital for Diseases of the Heart and Lungs.

Special Departments: Surgical, Laryngological, Radiological, Pathological, Electrocardiographic. Assistants are appointed to the Clinics, and a limited number of research workers to the Pathological Department. The in-patients staff visit generally in the afternoon; out-patients at 2 P.M. The post-graduate students are admitted on payment of fees which entitle them to attendance at clinics, post-mortem demonstrations, and operations. Special demonstration and lecture courses are provided, and a club room. Graduates desiring Assistantships in any department should address applications to the Head of that department. There is a Tuberculosis Dispensary (Boroughs of Bethnal Green and part Hackney) established at the Hospital, Victoria Park, E.2.

National Hospital for Diseases of the Heart.

The practice of the hospital (founded 1857), both in the wards and out-patient department, is open daily to post-graduates and others. Systematic courses of instruction, with lectures and clinical demonstrations, are arranged during the winter and summer sessions; in addition an intensive course, of a fortnight's duration, takes place in January, July, and October of each year. The hospital is fully equipped with all the modern instruments for the investigation of the diseases of the cardiovascular system, and facilities exist for those requiring practical instruction in electrocardiography, X rays, and other graphic methods. Clinical Assistants in the out-patient department are appointed from time to

ne. The hospital is situated in Westmoreland-reet, London, W.

DISEASES OF WOMEN AND CHILDREN.

ospital for Sick Children.

This hospital in Great Ormond-street, W.C., ntains 252 beds. The practice is open to students both sexes who have completed four years of edical study and also to qualified medical en and women. The medical staff are recog-sed by the University of London as teachers in iseases of Children. Arrangements have also en made with University College Hospital and the ndon School of Medicine for Women for the routine mission of their students of both sexes to clerkships d dresserships in the wards. Appointments are ade every three months to eight medical clerkships, nich are open to students of the hospital. Clinical struction is given daily by members of the visiting aff. Clinical Clerks are appointed once a month. the pathological department facilities are afforded post-graduates for obtaining theoretical and actical instruction in Clinical Pathology and cteriology, and in Medical Biochemistry in the thological and Biochemical Laboratories. Courses eight to ten Lecture-Demonstrations are given weekly intervals twice a year in both subjects linical Pathology and Bacteriology, and Bio-emistry.) Time spent in clerking and dressing is cognised by the Universities of London, Oxford, d Cambridge, as well as by the English Conjoint ard as part of the final curriculum. These ppointments are open to students of all recog-ed medical schools. In addition, special courses e held from time to time (generally in May and tober), as well as routine post-graduate instruction ily.

ueen Charlotte's Maternity Hospital and Midwifery Training School.

This hospital, formerly Queen Charlotte's Lying-in ospital, is situated in Marylebone-road, N.W. The spital receives over 2300 patients annually, besides ving a large out-patient department. Medical pils are received at all times of the year. Pupils ve unusual opportunities of seeing obstetric com-cations and operative midwifery on account of the ry large number of primiparous cases—nearly one-lf of the total admissions. Clinical instruction is ven on the more important cases which present emselves. They also receive valuable instruction in e Antenatal Department, where over 4000 patients tend yearly. Special Lecture-demonstrations are ven by members of the staff. Certificates of atten-nce at this hospital are recognised by all the Univer-ies, Colleges, and licensing bodies. Pupil midwives d maternity nurses are received and specially ined. A Residential College provides accommo-tion for students and qualified practitioners oth men and women), and is opposite the spital, with which it is in telephonic communi-tion.

Arrangements have been made for Medical Students receive the preliminary instruction in Practical idwifery recommended by the General Medical uncil.

oyal Waterloo Hospital for Children and Women.

This hospital, founded at the date indicated by its le, has within recent years undergone considerable tensions and has now 130 beds, while the latest ildings include a Nurses' Home, a new Operating eatre, and private pay beds. It has a full staff of rgeons, physicians, and gynæcologists, and also ecial departments. Amongst the many new ditions to the equipment of the hospital is an ectrocardiograph apparatus. A new Orthopædic partment is in use, and the Physiotherapeutic d Electrical Department has been extended and equipped. There are facilities for post-graduates to end the general and special clinics in medicine and surgery for in-patients, and for out-patients, including a genito-urinary clinic, a clinic for varicose veins, and the X ray department for gastro-intestinal diagnosis. Particulars of post-graduate courses, which are held from time to time, can be obtained from the Secretary of the Hospital, Waterloo-road, S.E., or from the Fellowship of Medicine.

Victoria Hospital for Children.

This hospital in Tite-street, Chelsea, S.W., contains 138 beds and a large out-patient department; the home at Broadstairs has 50 beds. Private wards in the Nurses' Home, named after H.R.H. Princess Mary (Viscountess of Harewood), at 29, Tite-street, adjacent to the hospital. Patients may be under the care of any medical practitioner holding an appointment on the staff of a recognised hospital, and the question of payment for his fees is arranged between him and the child's parents. Application for admission should be made to the Secretary.

Queen's Hospital for Children.

This hospital, for the sick children of the poor under 14 years of age, was formerly known as the North-Eastern Hospital for Children. There are 134 beds in London (Hackney-road, Bethnal Green, E.) and 36 at the seaside branch, "Little Folks" Home, Bexhill. Special departments in Ear, Nose, Throat, Skin and Eye, and Dentistry. Rheumatic Clinic in coöperation with L.C.C. schools weekly. A radiologist attends four times weekly. There are massage and light departments, and a special whooping-cough physician. The practice of the hospital is open to students by arrangement with the medical staff, and post-graduate instruction in children's diseases, lectures and demonstrations are given at times notified by the Fellowship of Medicine.

Paddington Green Children's Hospital.

This is a small hospital (42 beds) with a large out-patient department and a full staff, with Eye, Ear, Skin, Light, and Dental departments. The facilities which it offers for observation of clinical practice are used by the Fellowship of Medicine.

Hospital for Women.

This hospital in Soho-square, W., contains 82 beds. The teaching is available for post-graduates only in limited numbers. Operations take place daily at 2 o'clock except on Saturdays. The X ray department is supplied with the latest installation both for diagnosis and treatment, and experience can also be gained in the treatment of malignant disease by means of radium. Incorporated is the London School of Gynæcology, comprising attendance in out-patient department, operating theatre, clinical lectures, and X ray treatment.

Samaritan Free Hospital for Women.

Contains 70 beds. Qualified practitioners are admitted as clinical assistants to both the in- and out-patient departments. Full particulars may be obtained from the Secretary to the Medical Committee at the hospital, Marylebone-road, N.W.

East London Hospital for Children and Dispensary for Women.

There are 140 beds. Clinical instruction in Pediatrics is given to fifth-year Students at the hospital in Glamis-road, Shadwell, E. Two clinical clerkships for qualified or unqualified students are open every three months. Clinical assistants are from time to time appointed in the out-patient department. There is an Orthopædic Clinic on Wednesdays, and a Rheumatism Clinic on Thursdays. Special instruction in Infant Feeding. Post-graduate Clinical Demonstration on the second Wednesday in each month.

Chelsea Hospital for Women.

This hospital, situated in Arthur-street, Chelsea, S.W., has 100 beds, and a certain number are reserved for patients paying £5 5*s*. a week and small fees to the

surgeons for operations. There is a convalescent home of 32 beds at St. Leonards. At a large out-patient department the patients are seen at a nominal payment. The hospital caters for post-graduate teaching. In the out-patients' department clinical assistantships can be obtained which entitles the holder to attend out-patients and examine patients under the instruction of the visiting surgeons. The operating theatre is open to visitors, and all operations are demonstrated and discussed by the surgeons. Special intensive course, with lectures, special demonstrations, are held three times a year through the organisation of the Fellowship of Medicine.

Evelina Hospital and Belgrave Hospital.

The Evelina Hospital, Southwark (78 cots), and the Belgrave Hospital (76 cots), Clapham-road, also give facilities for out-patient practice.

OPHTHALMOLOGY.

Royal London Ophthalmic Hospital.

The attendance at Moorfields Eye Hospital (Moorfields, 1804–1899), City-road, E.C. (138 beds), is now very large. Operations are performed daily from 10 A.M. to 1 P.M., and four surgeons attend on each day. Students are admitted to the practice of the hospital, and special courses of instruction are given, which extend over a period of five months, by members of the Surgical Staff, beginning in October and March. The instruction and classes are arranged so as to meet the requirements for the various diplomas in Ophthalmology, both the preliminary examinations in Anatomy, Physiology and Optics, and those subjects required in the second part. Students of the hospital are eligible as house surgeons or clinical and junior assistants; these are appointed every three months.

Royal Westminster Ophthalmic Hospital.

This hospital, in Broad-street, Holborn, W.C. (85 beds, including 14 rooms for paying patients), has recently removed from its original site at Charing Cross to much larger premises, well adapted for teaching purposes. The clinics are held in the afternoons from 1 P.M. Operations are performed daily in the theatre at 3 P.M. Lectures and practical classes in the various branches of Ophthalmology, including Operative Surgery, Bacteriology, and Pathology, are held during the winter and summer sessions at 5 P.M. The practice of the hospital is open to both men and women practitioners, and medical students. Post-graduate students at the hospital are eligible for appointment as house surgeon, assistant house surgeon, refraction assistant (six appointments paid), and senior and junior assistants.

Royal Eye Hospital.

There are 44 beds and 2 cots at the hospital in St. George's-circus, Southwark, S.E. Clinical instruction is given to students and post-graduates daily at 2.30 P.M., and Lectures, Demonstrations, and Laboratory Classes are arranged in preparations for examinations in Ophthalmology. Apparatus has been installed for the Microscopy of the Living Eye. Post-graduate students are eligible for appointment as Clinical Assistants and as Refraction Officers. A new Clinic for paying patients under the Voluntary Hospitals Ophthalmic Clinic Scheme came into operation on July 1st.

Central London Ophthalmic Hospital.

This hospital, in Judd-street, St. Pancras, W.C., has 40 beds, and clinical teaching is given daily. Classes of instruction in the use of the ophthalmoscope, with demonstrations on cases, and also classes on other subjects, to meet the requirements of the Conjoint Board for the D.O.M.S., and of the University of London for the M.S. in Ophthalmology, are given during the winter months, commencing in October. This school is recognised as a teaching institution by the Universities of London and Oxford, as well as the English Conjoint Board. It receives a portion of the pupils of the University College Hospital for the purposes of ophthalmic training. The Pathological and Bacteriological Laboratories have been rendered available for the use of any ophthalmic surgeons who desire to send specimens for examination. A small fee is charged for a report. A clinical Demonstration is held by members of the staff at the Central London Ophthalmic Hospital at 5 P.M. on the first Tuesday of every month. Students of medicine and doctors are admitted free.

GENITO-URINARY AND VENEREAL DISEASES.

London Lock Hospital and Home.

In the institution at Harrow-road, W., founded 1746, there are 201 beds. In the male department and out-patient department in Dean-street, Soho, W., there are 37 beds. Male and female patients are seen at 91, Dean-street, Oxford-street, W.1, at any time from 9 A.M. until 9 P.M. daily, including Sundays. Intravenous injections are given at every clinic. Irrigations for males are given daily from 8 A.M. to 9 P.M. Female patients and children are seen daily at 283, Harrow-road, Paddington, W.9, from 9 A.M. until 8 P.M. Irrigations for females are given at any time. The hospital is linked up with the Fellowship of Medicine and special courses of lectures are held in May and November each year, and application for tickets should be made direct to the Secretary of the Fellowship. Only a limited number of practitioners and students are permitted to attend the practice of the Female Lock Hospital, and application should be made to the Dean at the Male Lock Hospital between the hours of 11 A.M. and 5 P.M., or to the Secretary at the Head office, 283, Harrow-road, W. 9. Telephone No. 4035 Paddington.

St. Mark's Hospital for Cancer, Fistula, and Other Diseases of the Rectum.

At St. Mark's Hospital for Cancer, Fistula, and other diseases of the Rectum, City-road, E.C. (founded 1835), for men and women, there are 62 general beds and 10 private beds. Operations are performed on Mondays, Wednesdays, and Thursdays at 2.30 P.M. Medical practitioners and students are invited to the operations and to the clinical instruction in the wards and in the out-patient department. Two fortnightly courses held during year in coöperation with the Fellowship of Medicine.

St. Peter's Hospital.

At St. Peter's Hospital for Stone and other Urinary Diseases, Henrietta-street, Covent Garden (established 1860) there are 30 beds for men and 2 beds for women and children. The X ray department is diagnostic only. A loan of radium salts for research work was made by the British Empire Cancer Campaign in 1925. Medical practitioners and students are invited to the clinical instructions which are given in the out-patient department daily, excepting that the only out-patient clinic open to medical women is that held at 2 P.M. Fridays for women and children and to the operations in the theatre on Mondays at 2.30 P.M., and Wednesdays and Fridays at 2 P.M. Post-graduate Courses of Lectures are given from time to time, dates being advertised in the medical journals.

A new Pathological Laboratory and Museum will be opened shortly at 10, Henrietta-street.

All Saints' Hospital.

The in-patient department (31 beds) of the All Saints' Hospital for Genito-Urinary Diseases is at Finchley-road, and the terms of admission are free or by payment according to means. The out-patient department in the Vauxhall Bridge-road provides clinical instruction through the Fellowship of Medicine, in addition to which demonstrations in cystoscopy and other branches of genito-urinary work are available for all medical practitioners at the Out

patient Department on Wednesday, Thursday, and Saturday afternoons, at 1.30 P.M., without fee.

ORTHOPÆDICS.

Royal National Orthopædic Hospital.

This institution, situated in Great Portland-street, W. (480 beds), is a good example of the fusion of small and scattered activities for the creation of an effective whole. The three orthopædic hospitals of the metropolis were combined for the formation of this central institution at the instance of the King's Hospital Fund, with the result that the grants from this Fund and the income from subscriptions can now be used to far better purpose and with economy. The hospital has also been approved by the Ministry of Health for the treatment of tuberculosis, the connexion between orthopædics and the therapeutics required in many forms of tuberculosis having become obvious. Country branch at Brockley Hill, Stanmore (280 beds). Both branches of the hospital are residential schools for physically defective children, certified by the Board of Education. Post-graduate courses of 14 days each are held twice yearly.

EAR, NOSE, AND THROAT.

Central London Throat, Nose and Ear Hospital.

This hospital in Gray's Inn-road, W.C., is open daily to all qualified medical practitioners on presentation of their visiting cards. Demonstrations of the cases and clinical instruction are given daily by the chief surgeon of each clinic. Lectures each Friday at 4 P.M. An intensive Course of Lectures (especially suitable to D.L.O. students), with Operative Surgery Class, Peroral Endoscopy Class, and Pathology Class is given twice yearly—in May and October. Preparatory courses in methods of Examination and Diagnosis at frequent intervals. Consultations on interesting cases take place on the fourth Wednesday in each month at 4 P.M. Clinical Assistants are appointed and are expected to hold office for at least three months. They are required to attend twice weekly at 1.30 o'clock for the afternoon, and at 4.30 o'clock for the evening clinics. New wing, with complete out-patient department and additional wards, was opened in August 1929.

Golden-square Throat, Nose and Ear Hospital.

The hospital is amalgamated with the London Throat Hospital, near Piccadilly Circus, W. 1. Clinical instruction in the diagnosis and treatment of disease is given daily in the out-patient department from 2 to 5 P.M., and on Tuesdays and Fridays from 6.30 to 9 P.M. There is an annual out-patient attendance of over 65,000. Minor operations are performed on Mondays, Wednesdays, and Fridays, at 9.30 A.M. The hospital now contains 96 beds. Practitioners and medical students are admitted to the practice of the hospital, and clinical assistants are appointed periodically.

Metropolitan Ear, Nose, and Throat Hospital.

The hospital (founded 1838) is in Fitzroy-square, W. The Out-patient Department is opened daily (Saturdays excepted) at 2.30 P.M. to all medical practitioners and senior students for acquiring clinical instruction and technical knowledge. Operations upon in-patients are performed on Tuesdays, Wednesdays, and Thursdays at 10 A.M. Clinical Assistants are appointed as vacancies occur.

SKIN.

London School of Dermatology.

The London School of Dermatology, St. John's Hospital for Diseases of the Skin, 49, Leicester-square, W.C., has an in-patient Department (33 beds) at 262 Uxbridge-road, W., and out-patient Clinics are held daily at 2 and 6 P.M. (Saturdays 2 P.M. only), when demonstrations are given on the cases presenting themselves. The Chesterfield Lectures, constituting a systematic course in dermatology, are given on Tuesdays and Thursdays at 5 P.M., from October to March, by the hon. medical staff of St. John's Hospital and the physicians in charge of the Dermatological Departments of the London Teaching Hospitals. The lectures are free to those attending the practice of the hospital and to registered medical students. At the end of the course an examination is held for the Chesterfield Medal in Dermatology, and is open to all medical practitioners, the examination fee being £1 1s. The electrical department is open daily from 2 to 4 P.M., except on Wednesdays and Saturdays. Laboratory Courses in the Pathology and Bacteriology of the Skin can be arranged.

London Skin Hospital and Hospital for Diseases of the Skin.

The London Skin Hospital (Fitzroy-square) and the Hospital for Diseases of the Skin (Blackfriars-road) admit students to their practice which is among out-patients, daily at 2 P.M. and 5.30 P.M.

CENTRES OUTSIDE LONDON AFFORDING EDUCATIONAL FACILITIES.

Nearly every hospital of a general character in the country having more than 150 beds falls within this category, and certain of them have already been noticed in connexion with the universities to which their clinical practice is attached. The hospitals vary much in size and scope.

The following alphabetical list includes the provincial hospitals which are recognised by the English Conjoint Board for a part of the required training in medical and surgical practice through clerkships and dresserships.

Bath Royal United Hospital.

This hospital contains 212 beds, 72 of which are situated in Combe Park, Bath, and are for paying patients only, and possesses X ray, Massage, Bacteriological Departments, a Pathological Laboratory, and a fine library. Secretary: Mr. J. Lawrence Mears, V.D. Clinics are held on Tuesdays (for women), and on Fridays and Saturdays (for men), at 5 P.M., and Ear, Throat, and Nose Clinics on Thursdays, at 4 P.M.

Bedford County Hospital.

This hospital at Bedford has 124 beds, including 15 beds in the paying and 13 beds in the maternity wards, X Ray and Pathological Departments. There is in connexion with the institution a convalescent home (20 beds) at Aspley Heath, nr. Woburn Sands. The hospital is approved by the University of London for the M.D. and M.S. Examinations. Secretary: Mr. Beauchamp Wadmore.

Bradford Royal Infirmary.

This hospital at Bradford contains 215 beds and, in addition, has 50 recovery beds at the Woodlands Convalescent Home, Rawdon. There are 4 Honorary Consulting Physicians, 1 Honorary Consulting Surgeon, 1 Honorary Consulting Laryngologist, 1 Honorary Consulting Gynæcologist, 1 Honorary Consulting Pathologist, and 1 Honorary Consulting Dental Surgeon. The acting Staff consists of 4 Honorary Physicians, 4 Honorary Surgeons, 1 Honorary Radiologist, 1 Honorary Laryngologist, 1 Honorary Ophthalmic Surgeon, 1 Honorary Dental Surgeon, 2 Honorary Assistant Physicians, 2 Honorary Assistant Surgeons, 6 Anæsthetists, 1 Pathologist, 1 Physician in charge of Radium Therapy Department, 1 Resident Surgical Officer, 1 House Physician, and 4 House Surgeons. There are special clinics for Orthopædic cases, for Electrotherapeutic and Sunlight Treatment, and for Radium Therapy. A new hospital of 360 beds with a self-contained block for 70 paying patients is in construction. Secretary-Superintendent: Mr. J. J. Barron.

Coventry and Warwickshire Hospital.

There are 307 beds available at the Main Hospital at Coventry (established 1840), and 40 beds at the Alcock Convalescent Hospital, Keresley (three and a half miles distance), which is used as an annexe. At the Main Hospital there are separate Medical, Surgical, Maternity, Children's and Accident Wards, also separate Ophthalmic Block complete with its own Theatre. There are separate departments for Clinics for Ear, Nose and Throat Diseases, X Ray, Electrical, and Sunlight Clinics, also V.D. Clinic. There is also an up-to-date Pathological Laboratory.

Derbyshire Royal Infirmary.

This general hospital at Derby (346 beds) was rebuilt in 1892–94. In recent years there have been numerous alterations and additions to keep pace with modern requirements. The hospital is built on the pavilion system and provides, in addition to the usual Medical and Surgical blocks, a separate Ophthalmic block of 40 beds, a separate Children's block of 34 beds (Medical and Surgical), Gynæcological Wards, and an Ear, Throat, and Nose Department. There is a large and well-equipped Out-patient Department, also separate Orthopædic, X Ray, Electrical, Pathological, and Venereal Diseases Departments. The Honorary Visiting Staff consists of 2 Honorary Physicians, 3 Honorary Surgeons, 1 Honorary Ophthalmic Surgeon, 1 Honorary Gynæcologist, 1 Honorary Assistant Physician, 2 Honorary Assistant Surgeons, 1 Honorary Assistant Ophthalmic Surgeon, 1 Honorary Pathologist, and 2 Honorary Surgeon Dentists. The salaried Medical Staff consists of a non-Resident Staff of 1 Surgeon-in-charge of X Ray and Electrical Departments, 1 Surgeon-in-charge of Venereal Diseases Department, 4 Anæsthetists, and a Resident Staff of 4 House Surgeons, 1 House Physician, and 1 Assistant House Surgeon and Casualty Officer. Registered Medical Students are admitted to witness the medical and surgical practice on payment of fees. Superintendent and Secretary: Mr. Walter Banks, F.C.S.I.

Gloucestershire Royal Infirmary and Eye Institution.

This hospital at Gloucester has 153 beds. Secretary: F. J. Symons. An Electrical and Massage department has been established and Venereal Clinic opened. Also Ear, Nose, and Throat department, X Ray department, Ultra-violet Ray department, Orthopædic department, Dental department, and Pathological Laboratory.

Hull Royal Infirmary.

This hospital at Hull contains 272 beds, and since its establishment in 1782 has undergone steady additions and improvements, including up-to-date Ophthalmic, Radiological, Nose, Throat and Ear, Dental, V.D., Violet Rays and Pathological Departments. Recent extensions include a new Operating Theatre, Nurses' Home, and extensions to the old X Ray, Electrical, and Out-patient Departments. Work is in progress on the erection of a new 500-bed hospital at Sutton-on-Hull. The staff consists of 3 Consulting Physicians, 4 Consulting Surgeons, 3 Consulting Ophthalmic Surgeons, 3 Physicians, 4 Surgeons, 1 Ophthalmic Surgeon, 1 Aural Surgeon, 2 Radiologists, 1 Pathologist, 2 Assistant Physicians, 2 Assistant Surgeons, 1 Assistant Ophthalmic Surgeon, 1 Assistant Aural Surgeon, 1 Dental Surgeon, 1 Assistant Dental Surgeon, 4 Anæsthetists, 1 Officer-in-charge of V.D. Department. Resident Staff: 1 House Physician, 1 House Surgeon, 1 Assistant House Physician, 2 Assistant House Surgeons, 1 Assistant Surgeon to Special Departments, 1 Casualty Officer. An annexe at Withernsea has accommodation for 30 patients.

Kent and Canterbury General Hospital.

The hospital at Canterbury contains 120 beds. Pupils of the staff are admitted to the practice of the hospital. Operations daily. Special departments include Ophthalmic, Ear, Nose and Throat, Venereal, Orthopædic, Electrical, Actinotherapeutic, X Ray, and Bacteriological. Secretary: Mr. W. T. Southwood.

Leicester Royal Infirmary.

At the General Infirmary, Leicester, there are 333 beds, and at the Children's Hospital in connexion, 70; venereal diseases, 17; total 420 beds. In addition 50 beds have been retained at local convalescent homes for the reception of early recovery cases, and £330,000 spent on bringing the accommodation of the institution to a modern standard of efficiency. This scheme has included the provision of four modern operating theatres, three new wings, and self-contained out-patients' department. The Children's Hospital has been reconstructed and enlarged by the addition of a third ward at a cost of £14,500. Pathological Laboratories and post-mortem rooms were erected at a cost of £11,000, also an orthopædic out-patient department at a cost of £9500, £5000 of which was provided by the Freemasons of the province as their war memorial. The Nurses' Home has recently undergone enlargement by 60 bedrooms, and now provides for 160 nurses and staff. A large house has been purchased to accommodate the night nurses. Other recent structural improvements comprise reconstruction of the kitchens, new temporary ward of 30 beds, and a new venereal disease department. There are twelve resident salaried medical officers—viz., four house surgeons, one casualty officer, two house physicians, three anæsthetists, and two dressers. Most of the posts are filled half-yearly and afford exceptional opportunities for post-graduate experience and senior students. Dressers are given an honorarium. Students who seek resident Dressers-hips should apply to the House Governor and Secretary. A post-graduate course of lectures is arranged annually by the Leicester Medical Association, and also clinical classes are held for graduates preparing for M.D. and M.R.C.P.

Norfolk and Norwich Hospital.

This hospital at Norwich has at present 386 beds. There is a convalescent home with accommodation for 35 patients at Cromer. The Honorary Medical and Surgical Staff consist of 2 Consulting Physicians, 3 Consulting Surgeons, 1 Consulting Radiologist, 1 Consulting Ear, Nose and Throat Surgeon, 3 Physicians, 3 Surgeons, 1 Assistant Physician, 3 Assistant Surgeons, 1 Surgeon, Ear, Nose and Throat Department; 2 Ophthalmic Surgeons, 1 Radiologist, 1 Pathologist, and 2 Dental Surgeons. There are 3 Honorary Anæsthetists and Honorary Assistants to the Ear, Nose and Throat Department, the X Ray Department, Ophthalmic Department, and Cardio-Vascular Clinic. Other medical officers are: 1 Assistant Pathologist and 1 Assistant to the Venereal Diseases Department. The Resident Medical Staff consists of 1 House Physician, 3 House Surgeons, 1 House Surgeon to the Ear, Nose, Throat, and Eye Department, and 1 Casualty Officer. There is also a Private Patients' Home which has at present 14 beds, and which will shortly be increased to 20. Students are admitted to the practice of the hospital for a fee of £5 5s. for six months. House Governor and Secretary: Mr. Frank Inch.

Northampton General Hospital.

Two new wings of this hospital at Northampton were opened in 1904 and the old buildings entirely renovated and rearranged. In 1926 a new isolation block of 30 beds was opened. The number of beds is 230. There is an up-to-date Pathological Laboratory; also X Ray and Therapeutic Department and V.D. Clinic. Two new operating theatres have been built, and a new ophthalmic in-patient department is in course of construction.

North Staffordshire Royal Infirmary.

The New Infirmary, opened in 1869, at Hartshill, Stoke-on-Trent, is built on the pavilion plan, has accommodation for about 346 patients, including Children's wards, a Bacteriological and Pathological department, and a department for the treatment of Diseases of the Eye, X Ray and Electrical department (including Ultra-Violet Ray Lamps); Cardiographic

epartment, a department for the treatment of iseases of the Ear, Nose, and Throat, an Orthopædic epartment, an Electrocardiograph department, ental department, and Venereal Diseases clinics, ncluding daily Intermediate Treatments. Recent xtensions comprise a new ward block, new X Ray nd Orthopædic departments with connecting corridors the existing infirmary, large extensions to the urses' home, a new boiler house, new chimney stack, nd a new laundry. Secretary and House Governor: Ir. W. Stevenson.

ottingham General Hospital.

There are at this hospital 377 beds available for edical and surgical patients, and 54 beds are in the etached branch known as "The Cedars" Branch f the General Hospital. The Medical and Surgical taffs consist of 1 Honorary Consulting Physician, Honorary Consulting Surgeons, 1 Honorary Conulting Physician in Venereal Diseases, 3 Honorary hysicians, 4 Honorary Surgeons, 2 Honorary ssistant Physicians, 2 Honorary Assistant Surgeons, Honorary Aural Surgeons, 1 Honorary Dermatolost, 2 Honorary Anæsthetists, 2 Honorary Assistant næsthetists, 1 Honorary Surgeon Dentist, 1 Honoary Medical Officer in Charge of X Ray and Electroherapeutic department, 1 Pathologist, and 6 Clinical ssistants. The Resident Medical Staff consists of House Physicians, 4 House Surgeons, 1 Aural House urgeon, and 2 Casualty Officers. The special departents are the Ear, Nose and Throat, Skin, Dental, assage, X Ray, Orthopædic, Electrotherapeutic, ltra-Violet Light. House Governor and Secretary: Ir. P. M. MacColl.

oyal Berkshire Hospital.

This hospital at Reading, which contains 243 beds, as enlarged in 1912, 1925, and 1928, and includes n Out-patient Department, a Casualty Department, n X Ray and Radiotherapeutic Department, Electroherapeutic and Massage Department, an Orthopædic epartment, a V.D. Clinic, a Laboratory, an Eye heatre, Eye Wards, a Maternity Ward, a Nursing ome, and a Private Nursing Staff, and two Motor nd one Horse ambulances. The hospital is pproved as a Training School for Nurses, and by he Ministry of Health for V.D. Treatment. The lagrave Branch, Calcot, opened in 1930, contains 0 beds for cases of disease of bones and joints and ose requiring open-air treatment.

oyal Devon and Exeter Hospital.

The hospital at Exeter contains 225 beds (including ecial children's wards) and has a good library, useum-post-mortem room, and pathological laboary. Attendance on the practice of his hospital ualifies for all the examining boards. There is also Private Nursing Staff attached to the hospital. For articulars as to fees, &c., apply to the Matron. A ew wing was added in 1897 and the "Victory" ing for the treatment of discharged disabled soldiers nd sailors completed and opened in 1922. Doctors practice may use the museum and library. The lectrical Treatment Department, opened in 1907, as enlarged in 1925, and now forms one of the ost important sections of the hospital. At the epartment for the treatment of genito-urinary iseases there are three sessions per week, two for en at 3 P.M. and 7 P.M., and one for women at 3 P.M.

oyal Hants County Hospital.

The hospital at Winchester contains 158 civilian eds. Secretary: Mr. Herbert Maslen.

oyal Hospital, Portsmouth.

The hospital contains 190 beds. There are athological, X Ray, Massage, and Medical and urgical Out-patient departments.

oyal Hospital, Wolverhampton.

There are 240 beds. Special Departments for hildren, Infectious Cases, Gynæcology, Maternity, ar, Throat, and Nose Diseases, Electrotherapeutic and X Rays, Orthopædics, Artificial Sunlight, Venereal Disease, Pathological and Biochemical Laboratories, Dentistry, Radium, and Electrocardiograph. There is an excellent medical library. The Resident Staff consists of one House Physician, two House Surgeons, and two Casualy Officers and Anæsthetists. Women's Department, one Resident Medical Officer. Pupils are allowed to witness the whole of the practice of the hospital, and to be present at operations, and have every opportunity of acquiring a practical knowledge of their profession. The hospital is recognised by the various Examining Bodies for a part of the requisite attendance on Medical and Surgical Practice. A course of Practical Pharmacy is given by the Pharmacist. Fees on application. Applications should be made to the Honorary Secretary of the Medical Committee.

Royal Salop Infirmary.

This hospital at Shrewsbury has 150 beds. Inpatients, 1780; out-patients 1436; out-patients' attendances, 27, 519; accidents and casualties, 4374; dental cases, 278. Secretary-Superintendent: J. W. Noble. The New Wing for the reception of Women and Children is capable of accommodating some 40 patients.

Royal South Hants and Southampton Hospital.

This hospital at Southampton contains 214 beds, but will be increased to 250 beds shortly, with every facility for clinical instruction. Special Departments: Ear, Nose, and Throat; Ophthalmic; Electro-Cardiograph; X Ray; Massage and Electricity; Ultra-Violet Ray; Venereal Diseases. Large Out-patient Department.

Royal Sussex County Hospital.

This hospital at Brighton has 237 beds and affords ample facilities for students, possessing a large out-patient department, including Ophthalmic, Dental, Dermatological, Gynæcological, X Ray, and Electrotherapeutic sections, and a well-appointed clinical research and bacteriological department. The hospital does not take resident pupils, but out-pupils may attend the practice of the hospital for any period not exceeding two years, on payment in advance of a fee, not exceeding 20 guineas, as the Board of Management shall direct.

Salisbury General Infirmary.

This hospital at Salisbury contains 159 beds. Maternity and antenatal ophthalmic wards; and Ear, Nose and Throat Wards; maternity and child welfare clinic.

South Devon and East Cornwall Hospital.

This hospital at Plymouth has 250 beds (including 10 for venereal diseases in a separate building). Special departments include Pathological, X Ray, Deep Therapy, Cardiographic, Ultra-Violet Rays, Electrotherapeutic, Orthopædic, Gynæcological and Aural; also medical and surgical out-patients. Pensioners are received as in-patients, and are also treated as out-patients.

Staffordshire General Infirmary.

This hospital was established at Stafford in 1766 and has over 100 beds; it is a Training School for Nurses.

West of England Eye Infirmary.

Students of the Exeter hospital can attend the practice of the Eye Infirmary (64 beds). A ward is set aside for newly-born babies suffering from infectious eye diseases. Mothers with babies are accommodated.

Worcester General Infirmary.

This hospital at Worcester has 132 beds. Pupils are taken by members of the Honorary Medical and Surgical Staff. New X Ray and Electrical and Wolfram Arc Light, Ear, Nose and Throat, and Orthopædic Departments have been erected and are now in use. Additional accommodation for the

Honorary Staff and Out-patients and also an Outdoor Shelter in connexion with the Children's Ward have been built as a memorial to King Edward VII., and fire-escape staircases erected. Plans have been prepared for an increase in bed accommodation to 200 beds; also Pathological Laboratory and two new Operating Theatres.

York County Hospital.

This hospital at York contains 180 beds. There are balconies for outdoor treatment, X Ray department, electrotherapeutic and massage department, actinotherapy installation, clinical laboratory, and a Zünd-Burguet apparatus for treatment of chronic deafness. There are clinics for Functional Nervous Disorders, Venereal Diseases, and Electrocardiography.

MEDICAL EXAMINING BODIES AND SCHOOLS IN SCOTLAND.

UNIVERSITY OF EDINBURGH.

Four Degrees in Medicine and Surgery are conferred by the University of Edinburgh—viz., *M.B.*, *Ch.B.*, *M.D.*, and *Ch.M.* The degree of *Ch.B.* shall not be conferred on any person who does not at the same time obtain the degree of *M.B.*, and the degree of *M.B.* shall not be conferred on any person who does not at the same time obtain the degree of *Ch.B.* No one is admitted to the degrees who has not been engaged in study for five years.

Candidates for the degrees of M.B. and Ch.B. must have attended for at least three academic years the medical and surgical practice either of the Royal Infirmary, Edinburgh, or of a general hospital elsewhere which accommodates not fewer than 80 patients and possesses a distinct staff of physicians and surgeons. They must have attended courses of instruction in Clinical Surgery and Clinical Medicine each of nine months, and courses of instruction in all the subsidiary subjects. They must have attended a course in Clinical and Practical Midwifery and have personally conducted 12 cases.

With respect to the places and institutions at which the studies of the candidates may be prosecuted the following regulations have effect:—Three of the five years of medical study must be spent in the University of Edinburgh. The remaining two years may be spent in any University of the United Kingdom, or in any Indian, Colonial or Foreign University or medical school recognised for the purpose by the University Court. Women are admitted to graduation in medicine under the same conditions as men.

Bachelors of Medicine and *Bachelors of Surgery* may proceed to the degrees of *Doctor of Medicine* and *Master of Surgery* after they have spent one year in the medical or surgical wards respectively of a hospital, or the Military or Naval Medical Services, or in scientific work bearing directly on their profession, or two years in practice. In each case an examination must be passed and a thesis submitted.

Post-graduate Instruction.—The University takes part in the Courses given under the auspices of the Edinburgh Post-graduate Courses in Medicine. In the departments of the Faculty of Medicine provision is made for research by students of graduate standing. In the University laboratories facilities will be provided for approved candidates for the Degree of Ph.D.

In connexion with the University and Royal Colleges Post-graduate Instruction is given each year, chiefly in the Summer Vacation (July–September). Special Courses are arranged for, and particulars may be had on application to the Hon. Secretary, Post-graduate Courses in Medicine.

The University of Edinburgh is especially rich in scholarships and prizes in medical subjects. Full particulars concerning these, as well as concerning the fees at different stages, can be obtained from the Dean of the Medical Faculty.

Edinburgh Royal Infirmary.

At this institution there are 1006 beds, including 42 cots for children. The clinical work of the Edinburgh student is done at the Royal Infirmary. Courses of Clinical Medicine and Surgery are given by the physicians and surgeons to male and female students. Special instruction is given on Diseases of Women, Physical Diagnosis, Diseases of the Skin, Diseases of the Eye, the Ear, the Larynx and the Teeth. Separate wards are devoted to Venereal Diseases, Diseases of Women, Diseases of the Eye, the Ear, Throat and Nose, and the Skin and also to cases of Incidental Delirium or Insanity. There is also a large and complete Radiological Department. Post-mortem examinations are conducted in the anatomical theatre by the pathologist and his assistants, who also give practical instruction in Pathological Anatomy and Histology.

The appointments are: 1. Resident physician and surgeons are appointed and live in the house free of charge. The appointment is for six months, but may be renewed at the end of that period by special recommendation. 2. Non-resident house physician and surgeons and clinical assistants are appointed for six months. The appointment may be renewed for like period by special recommendation. 3. Clerks and dressers are appointed by the physicians and surgeons. These appointments are open to all students and junior practitioners holding hospital tickets. 4. Assistants in the Pathological Department.

Facilities are given in connexion with the Post-graduate Courses arranged by the Edinburgh University and the two Royal Colleges jointly.

Royal Hospital for Sick Children.

The hospital at Sciennes-road, Edinburgh, has 132 beds, fitted with every modern improvement. A fully equipped out-patient department (medical and surgical) is conducted daily. Systematic courses of instruction, which qualify for graduation in the Edinburgh University and elsewhere, are given throughout the year by the staff. Each course consists of 50 meetings and combines medicine and surgery. Post-graduate Courses of Lectures are held during the summer vacation. Full particulars with regard to teaching can be obtained from the Dean's Office, University New Buildings, Edinburgh.

Edinburgh Eye, Ear, and Throat Infirmary.

Clinical Lectures and Instruction are given in the institution (with which is incorporated the Edinburgh Eye Dispensary) at 6, Cambridge-street, Lothian-road, open at 1 o'clock daily for out-door patients for Eye Diseases; Mondays, Thursdays, and Saturdays at 12 noon, and Tuesdays and Fridays at 4 P.M. for out-door Ear, Nose, and Throat Patients. Patients whose diseases require operations or extra care are accommodated in the house (10 beds). Practical Ophthalmoscopic Classes may be arranged, and Clinical Assistants are appointed from time to time. A Post-graduate Course in Diseases of the Ear, Nose, and Throat is held each academic term, commencing in May, October and January, and continuing for six weeks. The next course commences in October. The class meets at 5 P.M. on Tuesdays and Fridays, and the instruction, which is practical, is supplemented by lantern demonstrations. Full particulars from the Secretary, 32, Charlotte-square.

UNIVERSITY OF GLASGOW.

The University of Glasgow is both a teaching and degree-granting body, but admits to graduation only candidates whose preliminary examination and course of study conform to its own regulations. Within certain limits instruction given by recognised medical schools and teachers may be accepted, but not less than one-half of the subjects other than clinical must be taken in this or some other recognised university, and at least two years of the course must be taken in Glasgow University. Seven degrees, open both to men

nd women, are conferred: *M.B.* and *Ch.B.* (always onjointly), *M.D.* and *Ch.M.*; *B.Sc.* in Public Health; *D.Sc.* in Public Health; *B.Sc.* in Pharmacy; and *Ph.D.* in the Faculty of Medicine. A Diploma in Public Health (*D.P.H.*) is also granted.

All information as regards the extent and standard of the Preliminary Examination may be obtained by application to the Secretary, Scottish Universities Entrance Board, 81, North-street, St. Andrews.

For the degrees of M.B. and Ch.B. a curriculum of ive years is required. The candidate must attend a course or courses of instruction in each of the following subjects of study, extending over not less than the number of terms specified in each case, and including such class examinations as may be prescribed in connexion with the several courses:—Chemistry (including Organic Chemistry), with Practical Chemistry, three terms; Physics (with practical work), one term; Botany (with practical work), one term; Zoology with practical work), one term; Anatomy and Practical Anatomy, five terms; Physiology and Practical Physiology, three terms; Materia Medica nd Therapeutics (together or separately), each ubject, one term; Pathology and Practical Pathology, three terms; Medical Jurisprudence and Public Health (together or separately), each subject, one erm; Midwifery and Diseases peculiar to Women nd to Infants, two terms; Surgery two terms; Medicine, two terms. Candidates must attend for t least three years the Medical and Surgical Practice f a recognised hospital accommodating at least 0 patients and having a distinct staff of physicians nd surgeons. At least nine months' hospital attendnce is required on both Clinical Surgery and Clinical Medicine with nine months more of general hospital ractice; the student must have acted for six months s clerk in medical and dresser in surgical wards, nd must have had six months' outdoor practice; e must also have attended a course of Mental Diseases and of Practical Pharmacy (25 meetings), nust have been properly instructed in Vaccination t a public vaccination station, and must have ttended at least 20 cases of labour and the Practice f a Lying-in Hospital. The University also requires urther study in various special subjects: Ophthalmology, Diseases of the Ear, Diseases of the Throat and Nose, Venereal Diseases, Tuberculosis, Fevers, Vaccination. The final year consists of three intensive terms f study: one devoted to Midwifery and Diseases of Women, one to Surgery, and one to Medicine.

There are four Professional Examinations, the first omprising Botany, Zoology, Physics, and Chemistry; he second comprising Anatomy and Physiology; he third comprising Materia Medica and Therapeutics nd Pathology; and the fourth or final, comprising Medical Jurisprudence and Public Health, Surgery nd Clinical Surgery, Practice of Medicine and linical Medicine, and Midwifery and the Diseases eculiar to Women and to Infants.

The degrees of M.D. (*Doctor of Medicine*) *and Ch.M.* (*Master of Surgery*) are granted to candidates, not nder 24 years of age, who have previously obtained he double bachelorship on completing examinations, n Clinical Medicine for M.D. and in Surgical Anatomy, perations on the dead body, and Clinical Surgery for h.M. The higher degree of Doctor of Philosophy Ph.D.) is also conferred in the Faculty of Medicine. andidates must already have obtained a degree (or quivalent diploma) from an approved University or ollege and must prosecute a course of special study r research for two or three years and given evidence f satisfactory progress. A thesis must be presented or approval by the Senate on the recommendation f a Special Committee. The candidate may be equired to undergo an oral or other examination on he subject matter of the thesis.

Post-graduate Medical Teaching is available under he auspices of Glasgow Post-Graduate Medical Assoiation, which is representative of practically all the eaching Institutions in Glasgow. Weekly demonrations for practitioners are given throughout the winter and spring, and comprehensive courses of instruction during the summer and autumn. There is a General Medical and Surgical Course during the last two weeks of August and the first two weeks of September. This is a whole-time course and includes most of the subjects of interest to the general practitioner. The forenoons are occupied with General Medicine and Surgical Diagnosis and Minor Surgery in the Royal Infirmary and in the Victoria Infirmary. In the afternoons special subjects are dealt with in some of the special hospitals or in the special departments of the general hospitals—two subjects each afternoon. On the four Saturday forenoons Tuberculosis and Infectious Fevers are demonstrated at Ruchill Fever Hospital. Arrangements have also been made whereby a limited number of graduates may become attached to wards or out-patient departments nominally as clinical assistants for definite periods throughout the year. As such they work under the direct supervision of the physician or surgeon in charge, and carry out such detailed investigations as directed. Further information may be obtained from the Secretary of the Association, 9, Woodside-terrace, Glasgow.

There are many Bursaries, Scholarships, and Prizes in connexion with the Medical Course.

Glasgow Royal Infirmary.

The ancient connexion between the University of Glasgow and the Royal Infirmary was revived in 1911, when four University Chairs and several University Lectureships were established at the infirmary. New Lectureships in Materia Medica and Pathological Biochemistry were established recently, and a lectureship in Bacteriology has been founded. St. Mungo's College, which embraces and continues the original Royal Infirmary Medical School, is situated in the infirmary grounds. The infirmary has, including the Ophthalmic Department, over 800 beds. In addition to the large medical and surgical departments, there are special wards for diseases of women, of the throat, nose, and ear, skin, eye, burns, septic cases, and biochemical investigation. The wards are open to Women Students. Six house physicians and nine house surgeons, who board in the hospital free of charge, are appointed every six months; also five non-resident house physicians, nine non-resident house surgeons, and one non-resident dental house surgeon. Clerks and dressers are appointed by the physicians and surgeons. As a large number of cases of acute diseases and accidents of a various character are received, these appointments are very valuable and desirable. There is a modern and fully equipped Electrical Pavilion and Massage Department, and year by year the latest and most approved apparatus for diagnosis and treatment has been added. Post-graduate Classes are held during August and September in Clinical Medicine, Clinical Surgery, Clinical Gynæcology, Diseases of the Skin, Biochemistry, Diseases of the Throat, Nose and Ear, and in Diseases of the Eye, Tutorial Classes for senior students are also held in August and September.

For information regarding fees and other particulars, application should be made to the Superintendent.

Glasgow Western Infirmary.

This hospital of 642 beds adjoins the University. Special wards are set apart for Diseases of Women, Throat, Nose, and Ear, and for Affections of the Skin. In the out-patient department there are special clinics for Diseases of Women and for Diseases of the Throat, Ear, Nose, Teeth, Skin, Venereal Disease, and Electrotherapeutics. Radium centre for Glasgow and the West of Scotland. The Clinical Courses are given by the physicians and surgeons, each of whom conducts a separate class, and students require to enter their names at the beginning of the session for the class which they propose to attend. Special instruction is given to junior students by tutors or assistants, and clinical clerks and dressers are selected from the members of the class. All the courses of

clinical instruction are recognised by the University of Glasgow and the other boards in the kingdom. In the Pathological and Bacteriological Departments the courses are both systematic and practical, and extend through the winter and following summer; these are likewise recognised by the University for graduation. In addition Post-Graduate Courses are held. Eighteen resident assistants are appointed annually from those who have completed their course. In the Clinical Laboratory students receive laboratory instruction from the lecturer on clinical methods. A School of Massage, Medical Electricity, and Swedish Remedial Exercises has been established to qualify for the Certificate of the Chartered Society of Massage and Medical Gymnastics. Secretary: J. Matheson Johnston, C.A.

Victoria Infirmary.

This institution, situated at 67, Carlton-place, Glasgow, has 380 beds, and is the third of the extensive general hospitals in Glasgow to afford opportunity for clinical instruction to students. In addition to a full general staff there is a clinical research laboratory with pathologists and bacteriologists attached, radiological instructor, and a full assortment of specialists. The Bellahouston Dispensary, also with a clinical staff, is conducted in connexion with the Victoria Infirmary. For further particulars of the clinical practice application shoud be made to the Secretary and Treasurer.

Anderson College of Medicine.

Courses are given at Dumbarton-road, Glasgow, W., which qualify for all the licensing boards and for the Universities of Oxford, Cambridge, London, Durham, Edinburgh, and Glasgow (the latter two under certain conditions). Extensive accommodation is provided for Practical Anatomy, Practical Chemistry, Practical Botany, Practical Zoology, Practical Physiology, Practical Pharmacy, Operative Surgery, and Public Health. Ample provision has also been made for the comfort of students. Women students are admitted on the same terms as men, and the Carnegie Trust extends its benefactions to students of the College. (Full particulars may be obtained from the Carnegie Trust Offices, Merchants' Hall, Edinburgh.)

Candidates for the L.D.S. can obtain the full medical curriculum in Anatomy, Chemistry, Physiology, Surgery, Practice of Medicine, and Materia Medica. The courses special to Dentistry are conducted at the Dental Hospital, Glasgow.

Communications relating to the College to be addressed to the Secretary of the Medical Faculty. Communications relating to the Preliminary Examination in General Education to be addressed to the Educational Institute Office, 47, Moray-place, Edinburgh; and relating to the Triple Qualification and to the Dental Qualification to be addressed to Royal Faculty Hall, 242, St. Vincent-street, Glasgow.

Queen Margaret College.

Queen Margaret College (Women's Department of the University) is an integral part of the University of Glasgow. The classes are taught by professors of the University and other lecturers appointed by the University Court, and it is governed by the University Court and Senate. The curricula, regulations, and fees are the same as those of the male students, and the University degrees are open to women on the same conditions as to men. The school of medicine is a special feature of the College, and gives full preparation for the medical degrees of the University. The women students attend classes in the various University Buildings at Gilmorehill and Queen Margaret College, the Royal Infirmary, the Western Infirmary, and the Victoria Infirmary. Facilities for clinical work are given in the Royal, Western and Victoria Infirmaries, in the Maternity, Royal Sick Children's, and other hospitals. The Arthur Scholarship is open every third year to students of first year; other Bursaries are open in Arts and Medicine, and women are admitted to certain University bursaries and fellowships.

St. Mungo's College and Glasgow Royal Infirmary.

The classes in St. Mungo's College qualify for the medical qualifications of the English, Scotch, and Irish Conjoint Boards, for the dental diplomas of the English, Irish, and Scottish Boards and, under certain conditions, for the various universities, including the University of London. Students who have fulfilled the conditions of the Carnegie Trust are eligible for the benefits of this Trust during the whole course of their studies at St. Mungo's College. Further particulars can be obtained from the Secretary of the Medical Faculty.

Royal Hospital for Sick Children.

This institution consists of: (1) a hospital at Yorkhill containing 275 cots, built on an elevated and central site close to the University, and opened in July, 1914; (2) a Dispensary, or Out-patient Department, in West Graham-street, opened in October, 1888; and (3) a Country Branch at Drumchapel, Dumbartonshire, containing 80 cots, opened in 1903. Children treated must not be over 13 years of age, nor suffer from infectious diseases. In 1929 there were 5359 patients treated in the wards, and the number of attendances of out-patients was 81,960. There are one professorship and four lectureships in the University of Glasgow in connexion with the hospital, one professorship and one lectureship on the Medical Diseases of Infancy and Childhood, one lectureship on Surgery and Orthopædics in relation to Infancy and Childhood, one lectureship on Biochemistry in relation to Infancy and Childhood, and one research lectureship on the Pathology of the Diseases of Infancy and Childhood. The lectures are both systematic and clinical, but particularly and chiefly the latter. In addition, special facilities are given for post-graduate study. Resident House Physicians and Surgeons are appointed every six months at May 1st and Nov. 1st. Full information may be obtained from the Medical Superintendent.

Glasgow Royal Maternity and Women's Hospital.

The average daily number of patients in the hospital at Rottenrow is 140, and of the 4000 cases admitted to the wards per annum, over 60 per cent. are classified as abnormal. There are also about 3500 mothers attended per annum in their own homes. The work of the antenatal wards with their 40 beds is supplemented by large antenatal clinics where over 4000 new patients are seen in the course of the year. Splendidly equipped Research Laboratories were opened in 1926. The Visiting Staff of the hospital includes a Pædiatrician, who gives daily attendance. The practice of the hospital affords a wonderful field for post-graduate study and experience. In addition to the joint courses for post-graduates as organised by the Glasgow Post-Graduate Association, the resources of the hospital are always available for those who wish to make a special study of obstetrics. Inquiries should be addressed to the House Superintendent.

Glasgow Royal Samaritan Hospital for Women.

Increased to 160 beds by building extensions completed in 1927, the hospital offers excellent facilities for clinical instruction in the diseases peculiar to women. Lectures and clinical demonstrations are given by members of the surgical staff to students and to post-graduates; and the hospital is represented on the Board of the Glasgow Post-Graduate Medical Association formed for coördinating post-graduate medical teaching in all the hospitals. The Royal Samaritan Lectureship in Gynæcology is a University Lectureship associated with the hospital.

For further information, application may be made at the hospital, or to the Secretary, 200, St. Vincent-street, Glasgow.

Glasgow Lock Hospital.

The hospital at 41, Rottenrow, Glasgow, contains 80 beds for the treatment of females suffering from Venereal Diseases. There is also a Labour Ward and a well-equipped Dispensary for out-patients

attendances. There is a Lecture Room and a Laboratory, equipped with modern appliances, where University classes on the subject are dealt with. Post-graduate classes are also held. Recently the hospital has been completely renovated and modernised. Full information from the Secretary and Treasurer, Mr. J. Neilson Gray, LL.B., 65, Bath-street, Glasgow.

Glasgow Ophthalmic Institution.

This institution, at 126, West Regent-street, and 131, Wellington-street (30 beds and six cots), is administered by the Royal Infirmary. Clinical and systematic courses of lectures for students during the winter and summer sessions. Operations on Wednesdays and Fridays. Post-graduate classes and demonstrations are arranged during the summer. For information regarding fees and other particulars application should be made to the Superintendent, Royal Infirmary.

Glasgow Eye Infirmary.

The wards and dispensary at Berkeley-street and Charlotte-street are recognised by the University of Glasgow for the purpose of instruction in ophthalmology for graduation in medicine, and by the Royal Colleges of Physicians and Surgeons of England for the Diploma in Ophthalmic Medicine and Surgery. A Venereal Centre has been established, and a Branch Dispensary has been opened in Clydebank. Post-graduate Classes are held. Secretary and Acting Treasurer, Mr. William M. Moore, 171, West Regent-street, Glasgow.

Glasgow Ear, Nose and Throat Hospital.

The hospital contains 54 beds. At out-patient and indoor departments at 306, St. Vincent-street, clinical instruction is given. A Research Department has now been installed. Post-graduate Courses are held during the year. Secretary: D. N. Mackay, 38, Bath-street, Glasgow.

UNIVERSITY OF ST. ANDREWS.

Four Degrees in Medicine and Surgery are conferred by the University of St. Andrews (United College, St. Andrews and University College, Dundee)—viz., *M.B.*, *Ch.B.*, *M.D.*, *Ch.M.*, a Diploma in Public Health, and Diploma in Dental Surgery (*L.D.S.*).

The extent and standard of the Preliminary Examination is determined by the Scottish Universities Entrance Board, constituted under Ordinance No. 70 of the Scottish University Courts (General No. 3—Regulations as to Admission to the Scottish Universities for purposes of graduation), in accordance with the terms of that Ordinance. A degree in Arts or in Science in any of the Universities of the United Kingdom and in some colonial and foreign universities exempts. The Preliminary Examination for graduation in Medicine and Surgery, Arts or Science, of the University of St. Andrews is accepted as equivalent to the Registration Examination required by the General Medical Council (the certificate to include the required subjects). Also the Final Examination for a degree in Arts or Science.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—A pre-registration examination is held in Physics and Chemistry. Candidates must have been engaged in medical study for at least five years. In each of the first four years the candidate must have attended at least two courses of instruction in one or more of the subjects of study specified below, each course extending over a session of not less than five months, either continuous or divided into two terms, or, alternatively, one such course along with two courses, each extending over a session of not less than two and a half months. During the fifth or final year the candidate shall be engaged in clinical study for at least nine months at the Infirmary of Dundee or at one or more of such public hospitals or dispensaries, British or foreign, as may be recognised for the purpose by the University Court. The candidate must have received instruction in each of the following subjects of study, including such examinations as may be prescribed in the various classes—viz., Anatomy, Practical Anatomy, Chemistry, Materia Medica, Physiology, Practice of Medicine, Surgery, Midwifery, and the Diseases peculiar to Women and Infants, Pathology, Bacteriology, Practical Chemistry, Physics, Elementary Botany, Elementary Zoology, Practical Physiology, Practical Pathology, Forensic Medicine, and Public Health. The candidate must have attended for at least three years the Medical and Surgical Practice either of the Infirmary of Dundee or of a General Hospital elsewhere with not fewer than 80 patients, with a distinct staff of physicians and surgeons, and recognised for the purpose by the University Court. Additional subjects of study are Practical Pharmacy, Mental Diseases, Practical Midwifery, Operative Surgery, Vaccination, Children's Diseases, Fevers, Ophthalmology, Diseases of the Ear, Throat, and Nose, Anæsthetics, Dermatology, Venereal Diseases, Tuberculosis, and Post-mortem Examinations.

With respect to the places and institutions at which the studies of the candidate may be prosecuted the following regulations shall have effect:—1. Two of the five years of medical study must be spent in the University of St. Andrews. 2. The remaining three years may be spent in any University of the United Kingdom or in any Indian, Colonial, or Foreign University recognised for the purpose by the University Court, or in such medical schools or under such teachers as may be recognised for the purpose by the University Court. Women are admitted to graduation in Medicine.

Professional Examinations for the Degrees of Bachelor of Medicine and Bachelor of Surgery.—Each candidate will be examined both in writing and orally, and also clinically where the nature of the subject admits, in the following divisions—viz., first, in Botany, Zoology, Physics, and Chemistry; second, in Anatomy and Physiology; third, in Materia Medica, Pathology and Bacteriology, Forensic Medicine and Public Health; and fourth, in Surgery, Clinical and Operative Surgery, Practice of Medicine and Clinical Medicine, and Midwifery and Gynæcology (Systematic and Clinical).

University College, Dundee.

The Medical School in St. Andrews University is carried on as follows. Part or whole of the medical curriculum of St. Andrews University must be taken here. Provision is made by St. Andrews University for instruction in the work of the first two years, including Anatomy and Physiology, in both St. Andrews and Dundee. The last three years of the curriculum must be taken in Dundee in University College, which is a constituent part of St. Andrews University.

Dundee Royal Infirmary.

In addition to the ordinary Medical and Surgical Wards (461 beds), there are special departments for Midwifery (In- and Out-door), for Diseases of Women, of Children, of the Eye, of the Ear, Nose, and Throat, and of the Skin; and for Clinical Pathology, Radiology, Electrotherapeusis, and Electrocardiography. A new Maternity Department is being built at a cost of £37,000. Clinical teaching is given to male and female students by the Honorary Staff; post-mortem examinations are conducted by the pathologists. All courses of instruction are recognised by the University of St. Andrews and the other Universities and Boards of the United Kingdom. Ten Resident Medical Officers are appointed every six months. Clinical clerks and dressers are attached to the Physicians and Surgeons; and Students are appointed as assistants in the pathological department. Further information may be obtained from the Medical Superintendent.

UNIVERSITY OF ABERDEEN.

The University of Aberdeen grants four degrees in Medicine and Surgery—viz., *M.D.*, *Ch.M.*, *M.B.*, and *Ch.B.* The Degree of Doctor of Philosophy (*Ph.D.*) is also granted in the Faculty of Medicine.

Degrees of M.B. and Ch.B.—Candidates, before entering on the curriculum, must have passed the Preliminary Examination or hold a qualification recognised as exempting from such examination, have attained the age of 17, and have passed the Pre-registration Examination in Physics and Chemistry.

The curriculum for the degrees extends over a period of five years, during which attendance is required in the following subjects: Botany, Zoology, Physics, Chemistry (Systematic and Practical), Anatomy (Systematic and Practical), Physiology (Systematic and Practical), Materia Medica and Therapeutics, Practical Pharmacy, Pathology (Systematic and Practical), Medical Jurisprudence, Public Health, Surgery, Medicine, and Midwifery.

Candidates must attend for at least three years the medical and surgical practice of a recognised hospital, they must have attended courses of at least nine months in clinical medicine and clinical surgery, and have acted as clerk in the medical and dresser in the surgical wards of a hospital. Attendance is required on the practice of a dispensary or the out-practice of a hospital and also on courses in Mental Diseases, Fevers, Ophthalmology, Post-mortem Examinations, Venereal Diseases, Tuberculosis, Radiology, X Ray, Therapeutics and Electrical Treatment, and Clinical Chemistry, and other special subjects. The candidate is also required to have been properly instructed in Vaccination and to have attended at least 20 Midwifery cases.

Degrees of M.D. and Ch.M.—Candidates for either of these degrees must already hold the degrees of M.B. and Ch.B. of Aberdeen. A thesis (in duplicate) has to be presented and an examination has to be passed in Clinical Medicine (or in some special Department of Medical Science) or Clinical Surgery, as the case may be.

Degree of Ph.D.—For this degree candidates must pursue a course of special study or research during a period of nine academical terms as Research Students in the University of Aberdeen or in any College or Institution that may be affiliated thereto. A Thesis (in duplicate) must be presented for approval.

A diploma in Public Health is granted by the University to graduates in Medicine of a University in the United Kingdom, after a special examination.

Scholarships and Prizes.—In the Faculty of Medicine of the University of Aberdeen there are the following Bursaries, Scholarships, and Prizes:—Bursaries: about 24 Bursaries (competition and presentation) are open each year, of £10 to £45 per annum in value, most of them being tenable for three years. Scholarships: five Post-graduate Scholarships, ranging in value up to £250 per annum. Prizes and Medals: 15 Gold Medals and Prizes for proficiency in special departments.

Aberdeen Royal Infirmary.

There are 366 beds. The main clinical work of the students is done in the infirmary with its general and special facilities, including a Department of Clinical Chemistry.

Aberdeen Royal Mental Hospital.

This hospital contains about 900 beds. The class of Mental Diseases meets at the University of Aberdeen, and clinical instruction is given at the hospital during three months in summer. Physician-Superintendent, Dr. R. Dods Brown.

Other Hospitals.

Students have the opportunity of attending the following institutions: City Fever Hospital, Sick Children's Hospital, General Dispensary, Lying-in and Vaccine Institutions, and Ophthalmic Institution.

SCOTTISH MEDICAL CORPORATIONS GRANTING DIPLOMAS.[1]

CONJOINT EXAMINING BOARD.

The Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow have made arrangements by which, after one series of examinations, held in Edinburgh or Glasgow, or both, the student may obtain the diplomas of the three bodies. This is the Scottish Conjoint Board. The three bodies grant their Single Licences only to candidates who already possess legal qualifications in Medicine or Surgery.

The hospitals which are recognised by the Scottish Conjoint Board as places where professional study for their diplomas can be pursued are all those institutions which feed the medical faculties of the universities, as well as all the places which are recognised by the English and Irish Conjoint Boards.

Professional Education.—The candidate must produce certificates or other satisfactory evidence of having attended the following separate and distinct courses of instruction: Physics, three months; Elementary Biology, 2 terms; Elementary Organic Chemistry, one term; Anatomy, Practical Anatomy, 5 terms; Theoretical, including Biochemistry and Biophysics, 5 terms; Physiology, Materia Medica, 2 terms; Pathology (including Practical Pathology), 3 terms; Practice of Medicine, 2 terms; Clinical Medicine, 3 terms; Principles and Practice of Surgery, 2 terms; Clinical Surgery, 3 terms; Midwifery and Gynæcology, 2 terms; Diseases of Children, one term; Medical Jurisprudence, one term; and Public Health, one term. The certified attendance on lectures, demonstrations, and practical work must not be less than three-fourths of the total number of roll-calls. Every student undergoes a course of Practical Midwifery, but before attending at labours he is required to attend a course of lectures on Surgery and Midwifery and to hold the offices of Clinical Medical Clerk and Surgical Dresser. He must also attend for two and a half months' instruction in Practical Pharmacy; the certificate to be signed by the teacher, who must be a member of the Pharmaceutical Society of Great Britain, or the superintendent of the laboratory of a public hospital or dispensary, or a registered practitioner who dispenses medicines to his patients, or a teacher of Practical Pharmacy.

The student must attend for 27 months the Medical and Surgical practice of a public general hospital containing on an average at least 80 patients available for clinical instruction and possessing distinct staffs of physicians and of surgeons. He must act as Surgical Dresser and Medical Clinical Clerk for not less than nine months in the wards in each case, and receive practical instruction in administration of anæsthetics. He must attend for three months the practice of a public dispensary especially recognised by any of the above authorities, and three months' attendance at the out-patient department of a recognised general hospital. This attendance should be made after the student has passed the First and Second examinations.

Candidates are also required to attend the following three-monthly courses: Diseases and Injuries of the Eye; Insanity; Infectious Diseases; Gynæcology; Diseases of Children. The curriculum lasts for five years, the fifth year being devoted to clinical work.

There are four professional examinations:—

First Examination includes Systematic and Practical Biology, Chemistry and Physics.

The *Second Examination* must be Written, Practical, and Oral, and consist of the following subjects:—(1) Anatomy and Embryology, and (2) Physiology, including Histology (if not included in Anatomy), Biochemistry, and Biophysics. Candidates may be

[1] Regulations which apply to candidates who register as medical students after Oct. 1st were issued just before going to press.

admitted to this Examination on production of the necessary certificates of curriculum.

The *Third Examination* must be Written, Practical and Oral, and consist of the following subjects:—(1) Pathology, including Bacteriology and Morbid Anatomy, and (2) Pharmacology (Theoretical and Practical), including Pharmacological Chemistry, the Principles of Therapeutics, and Prescription Writing. Candidates may be admitted to this Examination on production of the necessary certificates of curriculum.

The *Final Examination* must consist of the following subjects[2]:—(1) Medicine, including Therapeutics, Applied Anatomy and Physiology, and Clinical Pathology with Practical Medicine; (2) Surgery, including Applied Anatomy and Physiology, Clinical Pathology, with Practical Surgery; (3) Midwifery and Diseases of Women, Clinical Obstetrics and Gynæcology, with Practical Midwifery; and (4) Medical Jurisprudence and Public Health. Medicine, Surgery, and Midwifery must be taken together, and Medical Jurisprudence and Public Health, and not earlier than on the conclusion of five Winters and five Summers of Medical Study, provided that a period of 36 months has elapsed since passing the Second Professional Examination. The Schedule for the Final Examination must contain a summary of the entire Course of Study, and, properly attested or proved by Certificates, must be lodged with the Inspector, and the fee paid, not later than one week before the examination. At the same time there must be produced a Certificate to show that the Candidate is not less than 21 years of age. No Candidate can be exempted from examination on any subject of the Final Examination (with the exception of Medical Jurisprudence and Public Health) unless he has already passed in the subject at this Board.

In addition to the Written and Oral Examinations, all Candidates must be subjected to Clinical Examinations in Medicine, Surgery, and Midwifery and Gynæcology, which shall include the Examination of Patients, Physical Diagnosis, the Clinical use of the Microscope and of other instruments, Clinical Chemistry, Surgical Appliances, Bandaging, Surface markings, Skiagrams, &c. The Oral Examination include the recognition of specimens. All Candidates for the Final Examination must complete the three portions (Medicine, Surgery, and Midwifery) within a period of 19 months.

There are four periods of examination annually.

The Registrar in Edinburgh is Mr. David Thomson, 49, George-square; and the Registrar in Glasgow, Mr. Walter Hurst, 242, St. Vincent-street, to whom fees and certificates must be sent for the respective examinations, and from whom particulars of fees can be obtained.

Edinburgh School of Medicine of the Royal Colleges.

The number of students varies much in the classes and subjects. It is within the limit to say that about 1000 students avail themselves each session of the opportunity of attending the school. The lectures qualify for the University of Edinburgh and other Universities, the Royal Colleges of Physicians and Surgeons of London, Edinburgh, and Dublin, the Faculty of Physicians and Surgeons of Glasgow, and other Medical and Surgical and Public Boards. Special courses of instruction for dental students are also included in the curriculum of this school. The practical classes and laboratories will open and the lectures commence on Oct. 1st. In accordance with the Statutes of the University of Edinburgh one-half of the qualifying classes required for graduation may be attended in this school. The regulations require that the fee for any class taken for graduation in Edinburgh shall be the same as that for the corresponding class in the University. The whole education required for graduation at the University of London may be taken in this school. Post-graduate Courses are conducted in conjunction with the University. Further particulars regarding the school, also its calendar (price 6*d.*), may be had on application to the Dean of the School, Surgeons Hall, Edinburgh.

[2] Candidates at the Final Examination may be examined on Diseases of Children, Fevers, Tuberculosis, Insanity, Skin Diseases, Diseases and Injuries of the Eye, Diseases of the Ear Throat, and Nose, Radiology. Venereal Diseases, Orthopædics, Vaccination, and Anæsthetics.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

In addition to the Diplomas granted by the Scottish Conjoint Board, the Royal College of Physicians grants its Single Licence to candidates whose names are already on the Medical Register.

The Royal College of Physicians of Edinburgh grants a *Membership* and a *Fellowship*.

Membership.—A candidate, who must be a Licentiate of a British or Irish College of Physicians, or a graduate in medicine of a University, approved by the Council, and 24 years of age, is examined in medicine, therapeutics, and in any branch of the departments of medicine specially professed, such as general pathology, psychology, public health, obstetrics, gynæcology, diseases of children, tropical medicine, or medical jurisprudence.

Fellowship.—The Fellows are selected from the ranks of the *Members*.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

The Royal College of Surgeons of Edinburgh admits to the examination for its Single Licence any candidates who hold a Diploma in Medicine of any British, Indian, or Foreign university or of any British College of Physicians, or of the Society of Apothecaries of London or Apothecaries' Hall, Dublin, granted under the provisions of the Medical Act, 1886, whose preliminary examination and course of professional study is proved to be sufficient to fulfil the requirements of the College, or to those who have passed a full examination for any of the above. Female practitioners are admitted to the Licence of the College and also to the Fellowship, and the regulations apply to practitioners of either sex.

The College grants a diploma of Fellowship after examination to the holders of British surgical degrees or diplomas and the holders of recognised degrees of the Universities of Canada, Australia, New Zealand, and the Indian Empire.

The Fellowship.—Candidates must be 25 years of age and in practice for at least two years. The examination is written and viva voce, and includes surgery and surgical anatomy, operative surgery, and clinical practice. One optional subject must also be taken, the range of these specialisms covering nearly every branch of medicine. Candidates are not allowed to appear for more than three times at the examinations. One month's notice of intention to appear for examination must be given by the candidate to the College.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

The Royal Faculty of Physicians and Surgeons of Glasgow grants a Fellowship and a Licence to be held separately. The Licence is granted as a separate qualification to qualified practitioners in Medicine after examination in surgery, including surgical anatomy and clinical surgery.

Fellowship.—The Fellowship of the Faculty is granted after examination in medicine or surgery, together with an optional subject, which may be anatomy or physiology, or be selected from any special branch of medicine or surgery. Fourteen days' notice must be given by the candidate to the Faculty. In certain circumstances Fellows may be elected as a mark of distinction.

MEDICAL EXAMINING BODIES AND SCHOOLS IN IRELAND.

UNIVERSITY OF DUBLIN, TRINITY COLLEGE (SCHOOL OF PHYSIC).

Matriculation.—University students take the Entrance of Trinity College and a Junior Freshman Term or a special Medical Preliminary; Extern Students, any examination recognised by the General Medical Council.

Pre-registration Examination in Elementary Physics and Chemistry.—Before beginning the five years' Medical curriculum students must pass an examination in elementary Physics and Chemistry. This examination is held at the end of September, in January, in March, and in July. Courses in preparation for it may be taken in the School of Physic.

Degrees in Medicine (M.B.), Surgery (B.Ch.), and Midwifery (B.A.O.).—Candidates for these degrees must be of B.A. standing and must be for at least five academic years on the books of the Medical School, reckoned from the date of registration. The Arts course may be taken concurrently with the Medical course, and the B.A. degree need not be taken before the final medical examinations, but the Medical degrees are not conferred without the Arts degree. The following courses must be attended:—(1) Botany, Zoology, Physics and Chemistry; Descriptive and Applied Anatomy; Histology, Physiology and Applied Physiology; Pathology and Bacteriology; Materia Medica and Therapeutics; Medical Jurisprudence and Hygiene; Practice of Medicine; Surgery; Midwifery and Gynæcology. (2) Three courses of nine months' attendance on the Clinical Lectures of Sir Patrick Dun's or other recognised Hospital; (3) Practical Vaccination, one month's instruction; (4) Mental Disease, three months; (5) Practical Midwifery with Clinical Lectures, including antenatal and Infant Hygiene Clinics, also not less than 20 personally conducted cases, five months, one of which must be as a resident intern student; (6) Ophthalmic Surgery, three months. Three groups of examinations have to be passed. Preliminary Scientific Examination, including Physics and Chemistry, Botany, and Zoology. The Intermediate Medical, Part I., including Anatomy, Physiology, and Organic Chemistry; and Part II., including Applied Anatomy and Applied Physiology; and the Final Examination, which is divided into Part I., Materia Medica and Therapeutics, Hygiene and Jurisprudence, Pathology and Bacteriology; and Part II., Medicine, including Clinical Medicine and Mental Diseases; Surgery, including Operative and Ophthalmic Surgery; Midwifery and Gynæcology. Part I. may be passed in the fourth year, and Part II. completed at the end of the fifth.

Doctor in Medicine.—A Doctor in Medicine must have passed all the qualifying examinations and must be a B.A of three years' standing. He must also submit a thesis and pass an Examination before the Regius Professor of Physic.

Master in Surgery.—A Master in Surgery must be a Bachelor in Surgery of the University of Dublin of not less than three years' standing and must produce satisfactory evidence of having been engaged for not less than two years from the date of his registration in the study or study and practice of his profession. He must then pass a special examination.

Master in Obstetric Science.— A Master in Obstetric Science must be a Bachelor in Obstetric Science of two years' standing, and must produce evidence of having been engaged in the study of Obstetric Medicine and Surgery during two years. He is then required to pass a special examination.

Diploma in Gynæcology and Obstetrics.—A post-graduate diploma is conferred upon registered medical practitioners who take a six months' course at th Rotunda Hospital or other recognised institution, six months' course in Trinity College, and then pa a special examination. The minimum time require for the complete course is nine months.

Bachelor in Dental Science and Master in Dent Science.—The regulations under which these degree are awarded can be obtained by application to th Registrar of the School of Physic.

All Degrees and Courses of Instruction are open t women students.

Scholarships and Prizes.—1. Medical and Surgic Travelling Prizes, £100, awarded in alternate year 2. Bicentenary Memorial Prize, £30, awarded yearly and given to the Travelling Prizeman. 3. Sir Joh Banks Prize and Medal. 4. Edward Hallara Bennett Prize and Medal. 5. FitzPatrick Schola ship, awarded on results of Final Examinatio (interest on £1000). 6. Medical Scholarship, £2 per annum for two years, awarded in Chemistry Physics, Botany, and Zoology. 7. Medical Schola ship in Anatomy and Physiology, £20 per annum fo two years. 8. Henry Hutchinson Stewart Schola ships, one in Botany, Zoology, Chemistry an Physics, and another in Anatomy and Physiology awarded annually and valued at £10 per annum fo three years. 9. Henry Hutchinson Stewart Schola ship in Mental Diseases, awarded from time to time £50 per annum for three years. 10. John Malle Purser Medal, awarded annually in Physiology 11. Daniel John Cunningham Medal and Prize awarded annually in Anatomy. 12. Begley Student ship, £40 per annum for four years, awarde annually. 13. Kingsmill Jones Memorial Prize awarded annually in Natural and Experimenta Science, £15. 14. O'Sullivan Memorial Scholarship £48 awarded annually for excellency of record i school.

Post-graduate Instruction.—Arrangements have bee made, with the approval of the Board of Trinit College, for a post-graduate course of instruction a the School of Physic during the autumn from Monday Sept. 15th, to Saturday, Oct. 4th. A limited numbe of members of the class can reside in college room and dine on commons. Women graduates can b accommodated at Trinity Hall.

HOSPITALS AFFORDING RECOGNISED PRACTICE.[1]

The following hospitals afford practice recognise by the Irish Universities and Corporations.

Sir Patrick Dun's Hospital.

Classes both in Medicine and Surgery are held eac morning at Grand Canal-street, Dublin, from 9 o'cloc from Oct. 1st till the end of June. Special classe for junior students will be held in the wards durin the months of October, November, and December A Resident Surgeon, with salary, is appointed annually Six Resident Pupils are appointed every six months Twelve surgical Dressers and twelve Clinical Clerk are appointed each month. There are facilities fo women students.

The practice of the hospital is open to all students and the certificates are recognised by Dublin Univer sity, the National University, and Royal Colleges o Surgeons of England, Ireland, and Scotland. It i an official "Treatment Centre" for venereal diseases

Prizes and Medals.—Clinical medals and prize amounting to about £21 each will be awarded i Medicine and in Surgery respectively in accordanc with the will of the late Rev. Samuel Haughton, M.D.

[1] This list of the institutions recognised by the Conjoin Board of Ireland is supplemented in the regulations of th Colleges by those hospitals mentioned as recognised institu tions in Scotland and England. The recognised facilities fo clinical instruction in some of the Irish centres have bee described.

S.F.T.C.D. Candidates who fail to obtain these medals and prizes will be awarded special certificates in Medicine and Surgery provided they show sufficient merit.

Further information will be supplied by the Hon. Secretary to the Medical Board.

Adelaide Hospital.

Two Resident Surgeons and four or more Resident pupils are elected every six months.

Prizes.—The Hudson Scholarship, £30 and a Gold Medal, as well as the Hudson Prize, £10 and a Silver Medal, are awarded at the end of the session for proficiency in medicine, surgery, gynæcology, and pathology. In addition to this prizes are awarded in gynæcology and dermatology, and in clinical medicine and surgery for junior students. Three Wallace Beatty Memorial Bursaries are granted at the discretion of the Medical Board at the beginning of the Winter session. The certificates of attendance are recognised by all the Universities and licensing bodies in the United Kingdom.

Further particulars may be obtained from the Secretary of the hospital, Peter-street, Dublin.

Mater Misericordiæ Hospital.

This hospital, under the care of the Sisters of Mercy, containing 410 beds, is open at all hours for the reception of accidents and urgent cases. Clinical instruction is given by the Physicians and Surgeons at 9 A.M. daily. Ophthalmic Surgery is taught in the Special Wards and in the Dispensary. Surgical operations are performed daily. Connected with the hospital are extensive Dispensaries, which afford valuable opportunities for the study of general Medical, Dermatological, Surgical Diseases, and Accidents; a fully-equipped Biochemical Laboratory, a modern Electro-Massage Department, an Electrocardiograph room, and Radiological Department. Instruction is given on Pathology and Bacteriology. Three House Physicians, eight House Surgeons, and 18 Resident Pupils are elected annually. Dressers and Clinical Clerks are appointed regularly and certificates given for merit. Leonard Prizes will be offered for competition annually. Certificates of attendance are recognised by all the Universities and licensing bodies in the United Kingdom. There is a Private Hospital for the reception of Medical and Surgical cases. A Training School and a Home for Trained Nurses are connected with the Hospital, and Nurses who have passed a qualifying examination can be obtained on application to the Lady Superioress.

Entries can be made with any of the physicians or surgeons, or with the Registrar, 31, Fitzwilliam-square, Dublin. Detailed information may be obtained from the Secretary, Medical Board.

Mercer's Hospital.

This hospital contains 120 beds for medical and surgical cases, and arrangements have been made with the medical officers of Cork-street Fever Hospital whereby all students of this hospital are entitled to attend the clinical instruction of that institution and become eligible for the resident posts. There is a large dispensary for out-patients and a modern X ray department. An electrocardiograph has been installed. Students of the hospital are permitted to attend the gynæcological department, where they receive practical instruction. There are special wards for the treatment and study of children's diseases. A gold medal is awarded annually to the best student. During the past few years the hospital has undergone extensive alterations in order to bring it up to modern requirements. A House Surgeon and a House Physician is appointed annually. There are six men and two women Resident Pupils, and Clinical Clerks and Dressers are appointed from members of the classes.

For further particulars apply to Dr. Leonard Abrahamson, Hon. Sec., Medical Board, 40, Fitzwilliam-place, Dublin.

Richmond, Whitworth, and Hardwicke Hospitals.

These House of Industry hospitals at Dublin contain 330 beds—130 for Surgical Cases, 80 for Medical Cases, 78 for Fever and other Epidemic Diseases, and an Auxiliary Wing with 42 beds, devoted mainly to throat, nose and ear, and skin diseases. Two Resident Physicians and two Resident Surgeons are appointed each half year, in addition to a Resident Pathologist and a Resident Anæsthetist. Resident Clinical Clerks are appointed each quarter, and it has always been the aim of the Medical Board to ensure that each student spends at least six months in residence. Women students are eligible on the same terms as men. Ample facilities exist for post-graduate work in the various special departments, as well as in general medicine and surgery. Extensive alterations and improvements have recently been made in the X Ray, Electrotherapeutic, and Electrocardiographic departments.

For further information apply to Hon. Secretary, Medical Board.

Royal City of Dublin Hospital.

The hospital contains 158 beds and a special wing for the treatment of fevers and contagious diseases founded by the late Mr. Drummond. There is a large nursery where special opportunities are afforded for the study of diseases of children, both medical and surgical. There are also special wards for ophthalmic, aural, and gynæcological cases; also a department for the Erlangen Treatment by Deep Therapy. There is a largely attended out-patient department, where students are allowed to attend accidents and dress cases under supervision. Six resident pupils are appointed every three months. A House Surgeon and a House Physician are appointed annually.

For information apply to the Secretary.

Dr. Steevens' Hospital.

This hospital, at Dublin (Kingsbridge), contains 250 beds, of which 175 are now in use. There is accommodation for 10 resident pupils, each of whom is provided with a separate bedroom, and board is supplied by the hospital at a reasonable rate. There is an Electric Massage Department, a "Sun-Ray" and Diathermy Department, and an X ray Department. There are also two V.D. wards and a largely attended V.D. Treatment Centre, as well as a large empty ward re-equipped and opened as open-air ward for Tuberculous and other diseases of bone, 25 beds.

All information with regard to the terms for such residency can be had from the Resident Surgeon at the Hospital. Secretary: E. D. F. Banks.

Meath Hospital and County Dublin Infirmary.*

Jervis-street Hospital, Dublin.*

Rotunda Hospital.

The Rotunda Hospital, Dublin, is the largest combined gynæcological and maternity hospital in the British Empire. Over 4000 confinements are attended annually, and upwards of 1000 gynæcological patients admitted. Students can take out their necessary gynæcological and midwifery practical courses. The work of the hospital is carried on continuously through the year, and consists of daily clinical instruction in the maternity department, and examination and operations in the gynæcological department. Qualified students are given facilities for studying and assisting in the management of all abnormal cases so far as is practical. An antenatal dispensary is held three times weekly and all students are encouraged to attend. A special class in gynæcological examination and diagnosis is conducted by the Assistants to the Master. In addition there is a special class in operative obstetrics, limited in number. The pathological laboratory is under the supervision of a skilled pathologist, who gives special classes at intervals. There is a fully equipped X ray installation under the care of a competent radiologist.

* No returns.

A ward has been opened for the treatment of infantile conditions, and is under the care of a pædiatrician, who gives instruction in the out-patient department, which is held daily. The appointments on the staff of the hospital are given to qualified past students of the hospital who have taken the L.M., and consist of Extern Assistants for six months, one being appointed every three months. From these the Assistants to the Master are appointed. Women students can reside in the hospital on the same terms as men. The mess room and sleeping quarters have been decorated recently and reading rooms are provided. The L.M. is granted by examination after a six months' course. Fees for Intern students: one month £6 6*s*., months other than the first £4 4*s*., three months £12 12*s*., six months £21. Special gynæcological class £2 2*s*. per month.

For further particulars apply to the Master, Dr. Bethel Solomons, F.R.C.P.I.

Coombe Lying-in Hospital.

The Coombe Lying-in Hospital and Guinness Dispensary for the Treatment of Diseases peculiar to Women, Dublin, contains 70 beds, and consists of two divisions, one of which is devoted to lying-in cases and the other to the treatment of diseases peculiar to women. Lectures are delivered, practical instruction given, and gynæcological operations are performed in the theatres daily. There is a general dispensary held daily, at which instruction is given on the Diseases of Women and Children. There is a special afternoon dispensary held by the Master and his assistants, at which practical instruction in gynæcology is given. There is no extra charge for attendance at this Dispensary. There is accommodation for intern pupils, who enjoy exceptional advantages of acquiring a thorough knowledge of this branch of their profession. Women students can reside in the hospital. Clinical assistants are appointed from amongst the pupils as vacancies occur. Certificates of attendance at this hospital are accepted by all licensing bodies. Students can enter for attendance at any time, but preference is given to those entering from the first day of the month.

Further particulars may be had on application to the Master or the Registrar at the Hospital.

National Maternity Hospital.

This hospital at Holles-street, Dublin, was established in 1894. The hospital consists of Intern and Extern Maternity, Gynæcological Wards, and a Dispensary for the treatment of Diseases of Women and Children and an antenatal and postnatal branch. Every facility is given for the carrying out of practical work. Undergraduate and post-graduate courses are arranged at any time. Certificates of attendance at this hospital are recognised by all the licensing bodies. Clinical lectures are given daily and Oral lectures four times per week. The L.M. Diploma is given by special examination, which is held three times a year.

Further particulars can be obtained from P. T. McArdle, Esq., M.B., the Master, or from the Secretary, Holles-street, Dublin.

St. Vincent's Hospital and Dispensary.

This hospital was established at Dublin in 1834, with 200 beds. Clinical Lectures in Medicine and Surgery are held from October to June. Special classes for Juniors from October to December. Pathological and Bacteriological Demonstrations are given every Thursday, and instructions in the use of Laryngoscope and Otoscope for senior students every Saturday. Medals and Prizes: the Bellingham gold medal in Medicine and the O'Ferrall gold medal in Surgery are offered for competition at the end of the summer session, as well as junior prizes, also the McArdle Memorial Prize, value £20. There are a large Extern Department and a new Pathological Laboratory.

Further particulars from Hon. Secretary Medical Board, Wm. Doolin, M.B., F.R.C.S., 2, Fitzwilliam-square, Dublin.

NATIONAL UNIVERSITY OF IRELAND.

Matriculation.—All students must pass a matriculation examination; the examination taking place in June and September in Dublin, and at certain local centres, includes five subjects, three of which must be Irish, English, and mathematics. All students must pass in Irish except students not born in Ireland, and other students whose home residence shall have been outside Ireland during the three years immediately preceding their matriculation; but all such students will be expected to attend a course of instruction in Irish Literature and History prior to obtaining any degree in the University. The following are the subjects for examination:—(1) Irish. (2) Latin. (3) Greek. (4) French. (5) German. (6) Italian. (7) Spanish. (8) Portuguese. (9) Welsh, or any other modern language approved by the Senate. (10) English. (11) Mathematics. (12) History. (13) Geography. (14) Applied Mathematics, or (15) Physics as an alternative. (16) Chemistry. (17) Botany. (18) Agricultural Science. (19) Commerce. (20) Music, and for women candidates only (21) Physiology and Hygiene. Students entering for degrees in Medicine or Dentistry, if not already registered by the General Medical Council, must take Irish, Latin, English, Mathematics, and a fifth subject.

The medical degrees granted are:—

M.B., B.Ch., B.A.O.; M.D., M.Ch., M.A.O., Ph.D.—Printed forms of application for admission to any medical examination may be had from "The Registrar, The National University of Ireland, Dublin."

The Constituent Colleges of the National University of Ireland at which the full curriculum for medical degrees can be obtained are University College, Dublin; University College, Cork; and University College, Galway.

University College, Dublin.*

Matriculation.—Almost all the students of the College are matriculated students of the National University of Ireland. The pre-registration examination in physics and chemistry is taken after matriculation either at the beginning of or during the winter session. The course is of five years' duration and dates from the passing of the pre-registration examination.

Degrees of M.B., B.Ch., and B.A.O.—The First Examination includes Applied Physics, Applied Chemistry, Botany, Zoology, and Applied Biology. The examination may be taken in two parts: Part I., Physics and Chemistry; Part II., Botany and Zoology. Honours may be obtained only when both parts are taken as one examination. The Second Examination includes Anatomy and Physiology. Both must be passed at the same time. The Third Examination (Part I.) includes Pathology, Materia Medica, Pharmacology, and Therapeutics. Part II. (Third Examination), taken at the end of the Fourth Winter Session, includes Hygiene and Medical Jurisprudence.

The Final Examination in Medicine, Midwifery, Surgery, and Ophthalmology includes both the theoretical and the clinical branches. No student can enter for the M.B., B.Ch., or B.A.O. until the end of the fifth year after registration, when the curriculum has been completed. The degree of M.D. may be obtained either by examination or on published work.

A Post-graduate Summer Course is held each year, beginning about the middle of June. The D.P.H. Course extends over the year, beginning at the opening of the session.

University College, Cork.

In the School of Medicine students must have passed the Matriculation Examination of the University or some other recognised examination, and a preliminary examination recognised by the General Medical Council.

* No returns.

Medical Students who have passed the First Professional Examination of the Conjoint Boards of Ireland, England, or Scotland may be admitted to the rank of second-year students on making application to the Council. Similarly, students who have passed the Second Professional Examination of the same Boards may be admitted to the rank of third-year students; and those who have passed the Third Professional Examination of the Dublin Colleges, or of the Edinburgh Colleges and Glasgow Faculties, may rank as fourth-year.

The school is provided with physiological, toxicological, pathological, and pharmaceutical laboratories, materia medica, anatomical and pathological museums, as well as a collection of surgical and obstetrical instruments and appliances. There are dissecting-rooms, well-appointed physical, chemical, and biological laboratories, a large natural history museum in the adjoining building, and part of the College ground is laid out as a botanical garden. The plant houses are well filled with plants and are open to the students in the class of Botany. The Library contains about 70,000 volumes and is open daily during term time to students. The Medical Museum occupies a large room erected at the northern end of the medical buildings. There are Students' Clubs for men and women students of the College and various athletic clubs.

Residence of Students.—Students not living at home, or with relatives or friends, sanctioned by their parents or guardians, are required to live in a hostel or in recognised lodgings, and register their addresses each session. The Honan Hostel, adjoining the College, is equipped by private endowment. A number of sets of rooms, together with recreation and common rooms, are provided for lay students who may desire to live there. For full particulars apply to the Warden. The Ursuline Convent, Blackrock, has a house of residence, quite separate from their Secondary School, for Catholic women students.

Clinical Instruction.—Students may attend the South Charitable Infirmary and County of Cork General Hospital, Cork North Charitable Infirmary and City of Cork General Hospital, the Mercy Hospital, the Cork District Lunatic Asylum, the Victoria Hospital for Diseases of Women and Children, the County Lying-in Hospital, Bon Secours, Fever, the District, and Ear, Eye, and Throat Hospitals.

Complete information with regard to class fees, scholarships, and prizes can be obtained from the Dean of the Medical Faculty, and in respect of the hospitals from the Secretaries.

University College, Galway.

The College contains a well-lighted and ventilated dissecting room and an anatomical lecture theatre; physiological, pathological, pharmaceutical, chemical, and physical laboratories; anatomical, pathological, gynæcological, and materia medica museums; as well as large natural history and geological museums and an extensive library in which students can read and from which they can borrow books. In the School of Medicine there are 12 Entrance Scholarships, varying in value from £30 to £60 each, for which Medical Students compete with other students on the Entrance Course. In the Second, Third, and Fourth years three Scholarships in each year, value from £30 to £40 each, are reserved for Medical Students. H. H. Stewart Scholarships (£10 a year for three years) are awarded by the University in Anatomy and Physiology at Second Medical Examination amongst Students of the three constituent Colleges. Travelling Studentships (£200 a year for two years) are offered by the University for competition amongst Medical Graduates of the three Colleges of not more than two years' standing. Women students are eligible for all College and University Degrees, Distinctions, and Prizes. There are extensive grounds, a portion of which is occupied by a Botanic Garden and a portion is at the disposal of the College Athletic Union. There are several student societies in the College, including a Biological Society. There are adundant facilities for research and Post-graduate work in the Chemistry, Physiology, and Pathology departments. There are ample facilities for Women Students. Further information can be obtained from the Registrar of the College.

Clinical Instruction is given in the Galway Tuberculosis Hospital and in the Galway Central and Fever Hospitals, containing on an average 350 patients.

Central Hospital, Galway.

In this completely renovated hospital (300 beds), in addition to the Finer Surgical and Medical Departments, there are now Eye and Ear, Throat and Nose, Gynæcological and Obstetrical, Pathological, X Ray, Ultra-Violet Rays, and Electrical and Massage Departments. Students attend from University College, Galway. Medical and Surgical Clinics are held on alternate days during term. One Resident Physician and one Resident Surgeon are appointed every six months. Resident Students are admitted. The hospital is open to qualified medical men for post-graduate work.

QUEEN'S UNIVERSITY OF BELFAST.

There are six degrees in the Faculty of Medicine of the University—viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (B.Ch.), Bachelor of Obstetrics (B.A.O.), Doctor of Medicine (M.D.), Master of Surgery (M.Ch.), and Master of Obstetrics (M.A.O.) The University also grants a Diploma in Public Health and a Diploma in Psychological Medicine, particulars of which will be found in the University Calendar. The degrees of M.B., B.Ch., and B.A.O. are the primary degrees in the Faculty of Medicine, and are conferred at the same time and after the same course of study. No student is admitted to the final examination for these degrees until he has shown: (1) that he is a matriculated student of the University; (2) that he has completed the prescribed course of study in the Faculty of Medicine extending over a period of not less than five academic years from the date of his registration as a student of Medicine; (3) that he has passed the several examinations prescribed; (4) that he has attended in the University during three academic years at least the courses of study prescribed for such degrees (the Senate may accept, for not more than two academic years of the required five, courses of study pursued in any other University or School of Medicine approved by the Senate); and (5) that he has attained the age of 21 years. Every candidate for admission shall matriculate or fulfil such other test of fitness as may be prescribed by the Senate, or may be exempted from the matriculation examination by having passed similar examinations elsewhere. For information as to Scholarships and Prizes, inquiry should be made of the Secretary of the University.

Primary Degrees of M.B., B.Ch., B.A.O.—All candidates for these degrees must satisfy the examiners in the subjects of four examinations.

The First Medical Examination.—The subjects of this examination are Chemistry (Inorganic and Organic), Experimental Physics, Botany and Zoology. The examination will be divided into two parts which may be taken separately: I., Chemistry and Physics; II., Botany and Zoology.

The Second Medical Examination.—The subjects are Anatomy and Practical Anatomy, Physiology and Practical Physiology. Candidates who have previously passed the First Medical Examination may present themselves for this examination at the close of their second year.

The Third Medical Examination.—The subjects are: (1) Pathology and Practical Pathology; (2) Materia Medica, Pharmacology and Therapeutics; (3) Medical Jurisprudence; (4) Hygiene. Candidates who have previously passed the Second Medical

Examination may present themselves for Part I. of this examination at the close of the third year, and for Part II. at the end of the Winter Session of the fourth year. Attendance on a course in any subject of the Third Medical Examination shall not entitle a student to a certificate of attendance unless he has previously passed in all the subjects of the Second Medical Examination.

The Fourth Medical Examination.—The subjects are: (1) Medicine; (2) Surgery; (3) Midwifery; (4) Ophthalmology and Otology. This examination may be taken in two parts: I., Systematic; II., Clinical, Practical and Oral. Candidates who have previously passed the Third Examination may present themselves for Part I. of the Fourth Examination at the close of the fourth year, provided that they have fulfilled the necessary requirements as to attendance, &c., on the courses of instruction in the subjects of examination. Candidates who have passed Part I. of this examination may present themselves for Part II. at the close of the fifth year, provided that they have fulfilled the necessary requirements as to hospital attendance on the various clinical courses in the subjects of examination. Parts I. and II. may be taken together at the close of the fifth year. Attendance on a course in any subject of the Fourth Medical Examination shall not entitle a student to a certificate of attendance unless he has passed in the subjects of the Second Medical Examination.

Degrees of M.D., M.Ch., and M.A.O.—These degrees are not conferred until the expiration of at least three academic years, or in the case of graduates of the University in Arts or Science of at least two academic years, after admission to the primary degrees in the Faculty of Medicine. Every candidate must show that in the interval he has pursued such courses of study, or been engaged in such practical work as may be prescribed. These degrees may be conferred by the Senate either (*a*) after an examination, which includes written, oral, clinical, and practical examinations; or (*b*) on the submission of a thesis or other evidence of original study or research, to be approved by the Faculty of Medicine after an oral or other examination of the candidate on the subject.

The Medical School.—The Donald Currie Chemical Buildings contain a lecture theatre, a preparation room, a chemical museum, a large class-room for elementary practical chemistry, laboratories for qualitative and quantitative analysis, rooms for water and gas analysis, dark room for photographic purposes and balance room, provided with all modern appliances. The Anatomical Department contains a large and well-lighted dissecting-room, a lecture-room, a professor's and demonstrator's room, a bone-room, and a laboratory for microscopic and photographic work. The Medical Museum is in the same building. The Jaffé Laboratories for Physiology comprise a lecture theatre, laboratories for practical work in chemical physiology, histology, and experimental physiology, and in addition small private research rooms, including balance, galvanometer, and centrifuge rooms. The J. C. White laboratories, recently founded, are fully equipped for research in biochemistry and bacteriology. The Musgrave Pathological Laboratory.—In this department opportunity is afforded for research in pathology and bacteriology. The department is in touch with most of the hospitals in Belfast, and there is an ample supply of material for investigation by graduates in morbid histology, clinical pathology, and the bacteriology of infectious diseases. A course in pathology or bacteriology is given to graduates, and members of this class have an opportunity of seeing the methods employed in the various investigations carried out in the department for the Public Health Committee of the Corporation in connexion with water-supply, sewage disposal, meat- and milk-supply, and the diagnosis of cases of infectious diseases. The certificate issued to members of the class in bacteriology qualifies for the D.P.H. degree. The Pharmaceutical Laboratory is fitted and equipped for the work of practically instructing students in t compounding and dispensing of medicines.

Clinical Instruction.—The following institutions a recognised by the University as affording prop opportunities for clinical instruction: the Roy Victoria Hospital, the Mater Infirmorum Hospit the Union Hospitals, the Belfast Hospital for Si Children, the Belfast Maternity, the Ulster Hospit for Women and Children, the Ulster Eye, Ear, a Throat Hospital, the Belfast Ophthalmic Hospit the Purdysburn Fever Hospital, and the Belfa District Lunatic Asylum. Complete information ca be obtained from the respective Secretaries.

Royal Victoria Hospital, Belfast.

There are 436 beds. Students eligible for McGrat McQuitty, Malcolm, Coulter Smyth and Elwoo Scholarships aggregate annual value £185. Twel House Surgeons and House Physicians. Thirty-s resident pupilships, three months each, annuall for Senior Students, of which a proportion is allotted t Women Students, Special Departments for Radiolog Clinical Pathology, V.D., Dermatology, Gynæcolog Vaccine Therapy, Electrocardiography, Dentistr Radium Therapy.

Mater Infirmorum Hospital, Belfast.

This hospital contains 270 beds and is open at a hours for the reception of accidents and urgent case Clinical instruction is given daily by Physicians a Surgeons. Surgical operations are performed daily The out-patient departments in Medicine and Surger also the special dispensaries for Gynæcology, Ear, Ey and Throat, Electrotherapeutics, Venereal Disease are very largely attended and afford valuabl opportunities to students for the study of thos subjects. A House Physician and two House Surgeon are elected every six months. Resident pupils a admitted as the vacancies arise. Three Exhibition and a Gold Medal are competed for annually in Jun Certificates of attendance upon this hospital a recognised by all the Universities and licensing bodie in the United Kingdom.

Belfast Infirmary and Hospital.

There are 1700 beds. Clinical courses are give quarterly, and a course for D.P.H. in Hospita Intern Venereal Clinic in Infirmary under Corporatio scheme. Maternity Hospital recognised for Practica Midwifery training. Particulars may be obtained o application to the Hon. Sec. Visiting Medical Staf Certificate of vaccination class recognised by Loca Government Board. There is a department fo Cancer with 32 beds, and X Ray and Bacteriologica Departments.

Belfast Hospital for Sick Children.

At the hospital in Queen-street there are 45 beds Clinical instruction is given. During the Winte and Summer Sessions Courses of Lectures are delivere on the Medical and Surgical Diseases incidental t Infancy and Childhood. Demonstrations in Ophthal mology and Pathology are given, and ampl opportunities are afforded in the wards and in th Out-patient Department for gaining a practica and theoretical knowledge of the diseases of Infanc and Childhood. This Hospital grants Certificate in Diseases of Children, which are recognised by th various Examining Bodies. Certificates are als granted for post-graduate study. A Gold Medal i offered for competition at the close of the session.

Maternity Hospital, Belfast.

At this institution in Townsend-street there are 2 beds in constant occupation, and exclusively devote to Midwifery and Antenatal conditions. There is also a large district. The Queen's University of Belfas have erected a Students' Hostel in connexion wit the Hospital where six Students and Post-graduate are received each month. The University Tutor i Obstetrics resides in the Hostel and Student conduct their cases under his supervision. There

is a large Antenatal Department and a Department for Venereal Diseases. Communications should be made to the Hon. Secretary of the Medical Staff.

Ulster Hospital for Children and Women.

At this hospital in Templemore-avenue, Belfast (60 beds), clinical instruction is given to students in Diseases of Children, Gynæcology and Obstetrics. Special departments: Radiology and Actinotherapy, Eye, Ear, and Throat, V.D. Clinic and Antenatal Clinic. Gold Medal awarded annually. Two House Surgeons appointed from students of hospital.

Benn Ulster and Belfast Ophthalmic Hospitals.

At the Benn Ulster Eye, Ear and Throat Hospital, Clifton-street (30 beds), and Belfast Ophthalmic Hospital, Great Victoria-street (30 beds), practical demonstrations by the staff and occasional clinical lectures in the subjects of Ophthalmology, Otology, and laryngology are given. Clinical instruction is given daily.

Belfast Fever Hospitals.

City Fever Hospital, Purdysburn (360 beds); Union Fever Hospital (200 beds). Clinical Classes are held during the winter and summer sessions. Post-graduate (D.P.H.) Classes are also held. Dr. A. Gardner Robb, Lecturer and Medical Superintendent.

Belfast Mental Hospital.

Purdysburn Villa Colony. (1300 beds.) University Lectures and Clinics.

IRISH MEDICAL CORPORATIONS GRANTING DIPLOMAS.

CONJOINT EXAMINING BOARD.

The Conjoint Board of the Royal College of Physicians of Ireland and Royal College of Surgeons in Ireland requires of candidates the passage either of its own preliminary examination in the subjects of general education or proof that the candidate has passed one of the tests accepted by the General Medical Council as well as passing in the Pre-Registration Examinations in Chemistry and Physics and Biology.

Professional Examinations.—There are three professional examinations, the first of which cannot be passed earlier than the end of the second winter session, nor the final before the conclusion of full five years of medical study. Before being admitted to any of them the candidate must show that he has studied the different subjects in practice and theory for the requisite periods, certificates to this effect being accepted from the authorities of most of the recognised medical schools at home and abroad. The first examination deals with (*a*) Anatomy, and (*b*) Chemical Physiology and Histology. The second examination deals with (*a*) Pathology, (*b*) Materia Medica, Pharmacy, and Therapeutics and Ophthalmology, and may be taken separately.

Final Examination.—This is divided into three divisions, which cannot be completed until at least five years have passed in medical studies other than those for the Pre-Registration Examinations, and five years at least since the beginning of the curriculum. The divisions are (*a*) Medicine, including Fevers, Mental Diseases, and Diseases of Children; (*b*) Surgery, including Operative Surgery; (*c*) Midwifery, including Diseases of Women and Children, and the Practice of Vaccination.

Diploma in Psychological Medicine.—There are two examinations in connexion with this Diploma: Part I. consists of (*a*) Anatomy and Physiology of the Nervous System; (*b*) Psychology. Part II.: (*a*) Neurology, including Clinical and Pathological Neurology; (*b*) Psychological Medicine, including its legal relationships.

Further information can be obtained from the Secretary of the Committee of Management, Royal College of Surgeons, St. Stephen's Green.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND

The College issues its Licences in Medicine and in Midwifery to practitioners whose names appear on the Medical Register of the United Kingdom.

The Licence in Medicine.—The subjects of examination are: Practice of Medicine, Clinical Medicine, Pathology, Medical Jurisprudence, Midwifery, Hygiene, and Therapeutics.

The Licence in Midwifery.—Candidates must produce certificates of registration. A registered medical practitioner of five years' standing may be exempted from the examination by printed questions.

The Membership.—Examinations for Membership are held in February, June, and November.

The Fellowship.—Fellows are elected by ballot. Applicants must have been a Member of the College for at least one year and must have attained the age of 27 years.

Further particulars can be obtained from the Registrar of the Royal College of Physicians of Ireland, 6, Kildare-street, Dublin.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

The College issues its Licence in Surgery to practitioners whose names are entered either on the Medical Register for the United Kingdom, the Colonial Medical Register, or the Foreign Medical Register of the year in which he presents himself for examination, and who satisfies the Council that he has passed through a course of study and Examinations equivalent to those required by the Regulations of the Irish Conjoint Board.

Candidates are examined in General Surgery (paper and oral), Clinical Surgery, Surgical Pathology (oral), Operative Surgery, Surgical Anatomy (paper), and Ophthalmic and Aural Surgery (clinical).

Diploma in Midwifery.—A diploma in Midwifery is granted after examination to persons possessing a registrable qualification.

Fellowship Examinations.—Candidates for the Fellowship shall make application to the President and Council to be admitted to examination. They are required to pass two examinations—Primary and Final. Candidates may present themselves for the Final Examination immediately after passing the Primary part, provided they have complied with the necessary regulations. The subjects for the Primary Examination are (*a*) Anatomy, including Dissections; and (*b*) Physiology and Histology. The subjects for the Final Examination are Surgery, including Surgical Anatomy and Pathology For admission to the Final Examination the candidate must have passed the Primary Examination, and must be a Licentiate or Graduate in Surgery of a university or licensing body recognised by the General Medical Council; all such candidates must not be less than 25 years of age.

Further particulars can be obtained from the Registrar of the College, Stephen's-green West, Dublin.

Schools of Surgery.

The Schools of Surgery are attached by Charter to the Royal College of Surgeons and have existed as a department of the College for over a century. They are carried on within the College buildings and are specially subject to the supervision and control of the Council, who are empowered to appoint

and remove the professors and to regulate the methods of teaching pursued. The buildings have been reconstructed, the capacity of the dissecting-room nearly trebled, and special pathological, bacteriological, public health, and pharmaceutical laboratories fitted with the most approved appliances in order that students may have the advantage of the most modern methods of instruction. The entire building is heated by hot-water pipes and lighted throughout by the electric light. Winter Session commences in October; Summer Session in April. Scholarships and Prizes: Carmichael Scholarship, £15; Mayne Scholarship, £8; Stoney Memorial gold medal; Operative Surgery, gold and silver medals; Pierefoy Memorial Prize, value £150; Barker Prize, £26 5*s*.; H. Macnaughton-Jones gold medal in Obstetrics and Gynæcology; and class prizes and medals. Prospectuses and guide for medical students can be obtained post free on written application to the Registrar, Royal College of Surgeons, Stephen's-green W., Dublin.

APOTHECARIES' HALL OF IRELAND.

The Licence of this Hall is granted to students who present certificates of having fully completed the course of study as laid down in the curriculum and who pass the necessary examinations. The diploma of the Hall entitles the holder to be registered as a practitioner in medicine, surgery, and midwifery, with also the privileges of the Apothecary's Licence.

Candidates must pass two Professional Examinations, called the Primary Examination and the Final Examination, which are conducted at separate times, partly in writing, and partly practically and orally. The Primary and Final Professional Examinations are held twice a year—viz., in June and January, or such other dates as may be determined.

Candidates who produce satisfactory evidence of having passed an examination for a Degree or Licence in Medicine, conducted by any University or Royal College in the British Empire, or by any Foreign University whose Degrees are recognised in the Foreign List of the Medical Register, will be exempted from the Primary Examination.

The subjects for Part I. of the Primary Examination are: Anatomy, Physiology and Histology, including Bio-Chemistry; and for Part II., Materia Medica and Pharmacy, Pathology, and Medical Jurisprudence and Hygiene.

For the Final Examination the subjects are: (*a*) Medicine and Clinical Medicine and Clinical Methods. (*b*) Surgery—Clinical, Ophthalmic and Operative; and Surgical Anatomy. (*c*) Midwifery and Gynæcology, and Practical Pharmacy and Materia Medica (if not taken at Intermediate Examination).

Each candidate before receiving his diploma must produce evidence that he has attained the age of 21 years. The details of the course of education required and syllabus of the examinations will be supplied by the Registrar at 95, Merrion-square, Dublin.

PHARMACEUTICAL SOCIETY.

THE SCHOOL OF THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN is recognised by the University of London. The Society conducts examinations for registration as (*a*) Chemist and Druggist and (*b*) Pharmaceutical Chemist. Courses of Instruction are given for these examinations, in the latter case in conjunction with University College.

An Intercollegiate two years' course for the Final Examination for the degree of B.Pharm. of the University of London is also given in conjunction with University College. Medical students are admitted to the lectures and laboratory work in any or all the courses. Certificates of instruction in the School are received by the Conjoint Board of the Royal Colleges and by the University of London. Graduates of approved Universities may carry out the research work necessary for the thesis for the Ph.D. of the University of London in the Society's Research Laboratories; this degree may now be taken in Pharmacognosy or Pharmacy in the Faculty of Medicine. Several scholarships are also offered. Further information may be obtained from the Dean, Prof. Greenish, 17, Bloomsbury-square, London.

PRISON MEDICAL SERVICE.

CANDIDATES for the Prison Medical Service are approved by the Secretary of State for the Home Department on the recommendation of the Prison Commissioners. Preference is always given to candidates who have experience of lunacy. Application for employment may be made on a special form which can be obtained from the Secretary, Prison Commission, Home Office, London, S.W. In the smaller prisons the medical officership is part-time and is usually filled by practitioners in the locality, preference being given to those who have special experience of lunacy. In the large prisons the medical staff must devote their whole time to the Service. In the case of whole-time service, the appointment is in the first instance to the post of Medical Officer, Class II., and from this rank the Medical Officers, Class I., are selected as vacancies occur. The pay of the whole-time prison medical staff is as follows: Medical Officer, Class II., £350, rising by annual increments of £20 to £600, making the pay at present with bonus £485 8*s*. to £776 7*s*.; Medical Officer, Class I., £650, rising by annual increments of £25 to £800, plus bonus, making the pay £837 5*s*. to £995 11*s*. Unfurnished quarters are provided or an allowance in lieu is made. Study-leave is granted annually to two of the whole-time Medical Officers. There are 12 full-time medical officers of Class I. and 1 Class II., and 23 part-time medical officers. The number of vacancies is never large and promotion is slow.

GUILD OF ST. LUKE.

THE Guild of St. Luke was founded over 60 years ago by a few medical students, chiefly to meet their own religious needs. It now makes a wider appeal and its membership is open to all students and practitioners of medicine, both men and women, who are members of the Church of England, the clergy of which are eligible as Clerical Associates. The Chapter meets in every month of each term, and a festival service is held yearly at St. Luke's tide, usually at St. Paul's or Westminster Abbey. This year the service will be at the Abbey. Besides the parent Guild, there are a Women's Ward and a Hospital Student's Branch in London. There are also a Midland Counties Ward and a Cambridge Ward. Particulars of the objects and activities of the Guild and forms of application for membership can be obtained from the Secretary of the Guild of St. Luke, King's College, Strand, W.C.2.

WE take this opportunity of thanking the officials of Government Departments and the Deans and Secretaries of the various institutions for their kind coöperation in enabling us to bring the information contained in our Students' Number up to date.

VOLUNTARY STERILISATION OF BLIND WORKERS.—Speaking at the Modern Churchmen's Conference last week Mr. C. J. Bond, F.R.C.S., said his advice had recently been sought by a Statutory Committee charged with the supervision of the blind in their area. This Committee wishing to discountenance the marriage of blind workers under their care, had passed a rule providing that those who married without their consent would cease to receive benefit and employment by the Committee unless one or both parties to the marriage could produce a medical certificate that the marriage would be childless. Two blind young couples under the care of this Committee had, he said, expressed in writing their willingness to undergo sterilisation and so comply with the Committee's rule. If a Statutory Committee with the care of blind persons in their area were justified in such an action, surely, said Mr. Bond, the State is justified in requiring that persons who are liable to transmit serious mental or bodily defect should also undergo sterilisation.

THE LANCET.

LONDON: SATURDAY, AUGUST 30, 1930.

CONTINUITY IN MEDICAL TEACHING.

ONE thing that all authorities, alike in this country or abroad, are now agreed upon in respect of medical education is that the principle of continuity should prevail, so that the general scientific foundation laid in the pre-clinical period should be relied upon by students throughout their educational course. There was no manifest need 50 years ago to lay any stress upon so obvious a truth, for in those simpler days the medical students received their instruction from teachers who were themselves exemplars of continuity in its most practical sense. At least until the early eighties the teachers in the medical schools began their educational work by instructing the students in the preliminary subjects, and as the students passed in their period of probation from physics, chemistry, and biology, to anatomy and physiology, and thence to the strictly professional subjects, so their teachers went up the ladder, becoming demonstrators of anatomy and physiology; thus making good their claim for promotion to the medical staff. But already, 50 years ago, our knowledge of those preliminary subjects had developed to such an extent that it was impossible for the same man to keep track of advancing wisdom along general scientific lines and at the same time concentrate upon his real business in life, the prevention and relief of disease. And, be it noted, that concentration was more than ever required as the growth of the fundamental sciences opened up new vistas for therapeutics. Soon it was perceived that two acute questions arose for the consideration of all authorities concerned in the education of medical students. These questions were first, what should be the range of accomplishment required in the preliminary subjects, and, secondly, how should a continuity of instruction be maintained? Should the teachers of the preliminary subjects persevere in their instructions throughout the later course of the students' training, or should the clinical teachers be relied upon to recall to their students' attention the intimate and vital connexions between the fundamental sciences and professional equipment?

For the last two years these questions have demanded incessant consideration from the General Medical Council as the supreme authority upon medical education in the country, and recently a questionaire has been submitted to the qualifying bodies in the kingdom, the interrogatory taking a form which should elicit answers to the questions. The replies of the qualifying bodies, which in the first instance required supplementing, have now been published as an appendix to the report to the Council of its Education Committee. From these replies it is clear that the difficult position has always been apparent to the teachers in the medical schools, and that much forethought along different directions has been exercised to provide the desired continuity in the training of the students. That a common pattern of training has not resulted is a matter for no regret, since obviously, while still subject to the controlling hand of the General Medical Council, the various universities and affiliated schools must work along lines which experience dictates as most suited to the particular centres. But a general inclination emerges from the replies to the questionaire, taken as a whole, that reliance should be placed upon the willingness and the ability of the clinical teachers to introduce as far as possible in their teaching arguments derived from, and lessons clearly dependent upon, familiarity with the preliminary sciences. This collective opinion is based upon the view that the time of the medical student is now so occupied, or over occupied, with formal and necessary instruction in the clinical subjects, and with the acquisition of experience at the bedside, that the interpolation in courses of such intensity of formal instruction upon the preliminary subjects would give no fruitful results.

The Education Committee find it premature, upon the information received from the various schools, to come to any dogmatic decision as to the relative advantages of the several methods of obtaining the correlation of the pre-clinical with the clinical subjects. They point out that the value of the different schemes of teaching which now come under review may be appraised by the extent to which the questions actually set in the final examinations accord with the training. This is to relegate the solution of the difficulty to the future. Teachers and students alike will value any arrangements which fit the courses of instruction to the tests of examination, but as medicine becomes more integrally associated with general science, so will it become more necessary to face the real problem, which is to define the demands to be made upon those who are seeking qualification, while providing adequate training upon special lines through post-graduate instruction. When agreement prevails as to how far instruction in certain of the special subjects can be postponed, to be obtained after qualification in accordance with the individual bents of the newly qualified, then it should be possible to lighten the students' curriculum in making room for revision courses in general science to accompany clinical teaching. On all grounds there should be no delay in the organisation of post-graduate instruction in this country, as once again we are reminded by Dr. HARVEY SMITH'S informative Presidential Address at Winnipeg.

THE MEDICAL SERVICES

ROYAL NAVAL MEDICAL SERVICE.

THERE always have been, there are now, and there always will be a certain number of young medical men to whom life in the Royal Navy appeals more than does any other life of a medical man. The type referred to is the man who may have been brought up in Naval surroundings, he may have Naval relations, or he may just love the sea. To a man of this temperament a career as a Medical Officer in the Royal Navy offers very definite attractions. In these days his professional knowledge will most certainly not rust anywhere; but especially in the Naval Hospitals will he have opportunities of practising every branch of his profession, except, of course, diseases of women. He can obtain one of the 60 paid specialist appointments. These include medicine, surgery, diseases of the eyes, diseases of nose, ear and throat, radiology, anæthetics, genito-urinary and venereal diseases, physical training, bacteriology, pathology, and hygiene. He will be encouraged to work hard and play hard. He will see the world under ideal conditions, because wherever he goes he will be a welcome guest, as is always the case with those who are privileged to wear the King's uniform.

In any walk in life success and happiness depend primarily on two main conditions. You must like your fellow men and they must like you.

The right type of man for a Naval Medical Officer is a good doctor, keen on his work and keen on his play, unselfish and a gentleman.

If the doctor is of this type he is invariably everybody's friend. The Naval Officer and the blue-jacket are quick to recognise a Medical Officer who is keen on his work, thoughtful of his patients, and one who strives after improving the health of the Navy. Such a Medical Officer finds life agreeable as everyone is ready to befriend him, and nowhere can one find more delightful friends than in the Navy.

Officers who have held appointments as Medical or Surgical Officers in Civil Hospitals for any period prior to entry, after qualifying, are eligible under the regulations to have their seniorities ante-dated by not more than one year.

To help men to take higher qualifications opportunities are given, when the exigencies of the Service will permit, for medical officers to take post-graduate courses prior to sitting for these higher examinations. A large number of Naval Medical Officers since joining the Navy have taken qualifications such as M.D., F.R.C.S., M.R.C.P., D.P.H., D.T.M., D.O.M.S., &c. It is recognised that this is good for the Navy and good for the officer himself.

WORK OF THE NAVAL MEDICAL SERVICE.

In our large Naval Hospitals the medical, surgical, and specialist work is of a very high standard. The work is very exacting, and it is the aim of the Admiralty to arrange appointments as far as possible so that medical officers have an opportunity of alternating their work, not only at home and abroad, but also ashore and afloat.

To give Naval Surgeons opportunities for professional work has always been a very definite policy of the Admiralty, and within the last year or so this matter has received still further attention.

The General and Specialist Courses have been increased so that, as far as possible, every officer shall have a course of instruction of not less than four months' duration every four years. The number of specialists allowed is now 60 and the specialist allowance is 5*s.* a day.

The total number of Medical Officers in the Navy is about 400, including 1 surgeon Vice-Admiral (Medical Director-General), 6 Surgeon Rear-Admirals, and 20 Surgeon-Captains, and every improvement has been made towards giving increased opportunitie of advancement and accelerated promotion to th best men.

The advantages of a career with its period c strenuous clinical work, followed by a period of com parative leisure which can be devoted to study, &c are laid stress on in the Presidential Address of th War Section of the Royal Society of Medicine delivere on Oct. 10th, 1927.

The work and professional opportunities of th Service Medical Officer are described, but the addres is necessarily brief, and it is only by reading betwee the lines that one can really visualise the field fo work which lies before the keen Naval Doctor.

Not only has he this purely medical work to intere him. He has opportunities to emulate some of th great Naval Surgeons of the past, such as Darwi Huxley, and many others, who have contributed s much to science.

MEDALS AND PRIZES.

Gilbert Blane Medal.—This Medal is awarde annually to the Surgeon Lieutenant Commander wh obtains the highest aggregate marks at the examin tion for promotion to the rank of Surgeon Commande The award is subject to the approval of the Presiden of the Royal College of Physicians and Surgeon respectively and the Medical Director-General the Navy.

Other awards and prizes open to Naval Medic Officers are the Chadwick Naval Prize, the Nort Persian Forces Memorial Medal, and the Park Memorial Prize.

PLAY IN THE NAVY.

Recreation is a vital part of the Navy, and there no branch of athletics or field sports in which the Nav Officer does not have an opportunity of trying h hand. Not only is the champion encouraged b also the less proficient.

In every home port and on most foreign statio there are opportunities for football, cricket, tenn golf, rowing, sailing, swimming, and all other spor On some foreign stations the Naval Officer can g shooting and riding in plenty, and so cheap that can indulge in them on his pay alone. In civil life home only a rich man could get such magnifice shooting as the Naval Officer does is some parts of t world.

PAY AND ALLOWANCES.

Full Pay.

		£	£	
SURGEON LIEUTENANT (short service and permanent service)	from	450 to	493	per annu
SURGEON LIEUTENANT - COMMANDER (promoted after six years' service)	,,	593 to	627	,,
SURGEON COMMANDER (promoted after a further six years' service)	,,	763 to	967	,,
SURGEON CAPTAIN (promoted by selection)	,,	1104 to	1367	,,
SURGEON REAR-ADMIRAL (promoted by selection)		1782		
MEDICAL DIRECTOR-GENERAL (Surgeon Vice-Admiral)		2325		

Allowances.

An outfit allowance of £50 towards cost of uniform is given

Allowances when in charge of hospitals and sick-quarters	10*s.* and 5*s.* per diem.
Sixty Specialist allowances of	5*s.* per diem.
Allowances to Senior Medical Officers in flag ships	5*s.* and 2*s.* 6*d.* per diem.

Accelerated promotion can be gained under certain condition provision allowance and lodging allowance are paid wh victualling and accommodation are not provided. Servan allowance is also payable in certain appointments.

The extra allowances alluded to in this table are not to looked upon as very exceptional. About a quarter of t Medical Officers of the Navy are drawing extra allowances.

The cost of living in the Navy is cheap, and officer can live on his pay and enjoy life if he is r extravagant, especially if he does not embark

matrimony too early. A small amount of private means goes much further in the Navy than in civil life. The three vital points—pay, prospects, and promotion—of the naval medical officer can be grasped by referring to the above clear and brief table.

PENSION.

Naval Officers retire at certain ages according to the rank they have attained. Except for those promoted to the 27 higher posts, the usual retiring age is 50 as Surgeon Commander, the appropriate pension according to scale being £558 per annum.

With his experience in the Service, together with specialist qualifications, the Naval Medical Officer is able to obtain excellent openings on shore, being still at the age of 50 able to hold his own with his civilian confrères and being professionally at his best.

The scale of pensions is as follows :—

	Maximum retired pay.
SURGEON VICE-ADMIRAL ..	£1112 per annum, on vacating office.
SURGEON REAR-ADMIRAL ..	£940 per annum, at age of 60.
SURGEON CAPTAIN	£837 „ „ 55.
SURGEON COMMANDER	£558 „ „ 50.
SURGEON LIEUTENANT-COMMANDER AND SURGEON LIEUTENANT	£419 „ „ 45.

Officers permitted to withdraw receive gratuities on the following scale :—

	£
After 4 years' full pay permanent service ..	500
„ 8 „ „ „ „ ..	1000
„ 12 „ „ „ „ ..	1500
„ 16 „ „ „ „ ..	2250

Of recent years Medical Officers have been admitted into the Navy without entrance examination, and for short service, with the option of turning over to the permanent service, but it is anticipated that it will not be long before the Admiralty will revert to the old established system of entrance by competitive examination twice a year, in batches of about ten officers.

The Medical Director-General of the Navy, Queen Anne's Chambers, Tothill-street, London, S.W.1, would be glad to receive inquiries from prospective candidates.

Dental Branch.

The Naval Dental Service offers similar opportunities to qualified dental surgeons except that higher rank than that of the recently instituted Surgeon Captain (D) is not open to them. They are provided with suitable surgery accommodation equipped with modern appliances and supplied with all material required for their work, and there is every opportunity for them to maintain a high standard of professional skill.

Candidates are required to produce certificates of birth, registration, and of character, and must be physically fit for active service anywhere. An outfit allowance of £50 is payable to officers finally entered and commissioned. The rank of Surgeon Lieutenant-Commander (D) is attained on the completion of six years' satisfactory service. Promotions to Surgeon Commander (D) and Surgeon Captain (D) are made strictly by selection from the rank next below and are confined to officers who prove fitted in every respect for these ranks. The present establishment of dental officers is : 1 Surgeon Captain (D), 3 Surgeon Commanders (D), 60 Surgeon Lieutenant-Commanders (D) and Surgeon Lieutenants (D).

Provision has been made for candidates who have held, or who, at the time of passing the examination held or are about to hold, an appointment as Dental Officer in a recognised Civil Hospital. The time concerned, provided it does not exceed six months, may reckon for increase of full pay while on the active list.

On the completion of two years' service in the rank of Surgeon Lieutenant-Commander (D), dental officers on the Active List are eligible for a three months' post-graduate course at a dental hospital and school at the public expense, and will draw full pay while attending the course.

Pay.—The current rates of full pay for Dental Officers are as follows :—

	£ £
Surgeon Lieutenant (D)	374–459
Surgeon Lieutenant-Commander (D) (promoted after six years' service)	551–678
Surgeon Commander (D) (promoted by selection to fill vacancies in Establishment)	721–924
Surgeon Captain (D) (promoted by selection to fill vacancy in Establishment).. ..	1062–1314

The Regulations regarding Pension and Withdrawal Gratuities are the same as for Medical Officers in the corresponding Ranks.

In 1919, when new rates of pay for all Naval Officers were fixed, it was decided that 20 per cent. of these rates should be considered as due to the then high cost of living. The rates of pay shown above are those payable on and after July 1st, 1930, and represent a reduction of approximately 7 per cent. owing to the decrease in the cost of living. The 20 per cent. above mentioned is to be regarded as variable and subject to change on July 1st, 1931, and thereafter as may be decided, either upwards or downwards according as the cost of living rises or falls.

ARMY MEDICAL SERVICE.

Royal Army Medical Corps.

SINCE the publication of the Royal Warrant of 1926 further improvements have been made in the conditions of service in the Royal Army Medical Corps, and this service can be recommended as a career to young medical men.

In addition to the grant of permanent commissions, the War Office offer a number of temporary commissions in the Royal Army Medical Corps, the holders of which may be invited at the end of 12 months' service, if suitable, and provided that vacancies exist, to accept permanent commissions in the Royal Army Medical Corps. If a permanent commission is accepted, the temporary service is allowed to count as the equivalent of permanent service for promotion, increase of pay, and retired pay. These conditions enable the young medical man to make acquaintance with army life, without detriment to his ultimate prospects, before deciding whether to make a permanent career in the Royal Army Medical Corps.

The regulations for admission giving full details should be obtained from the Permanent Under Secretary of State (A.M.D. 1), War Office, Whitehall, London, S.W. 1, and carefully studied. A personal interview with a representative of the Director-General, Army Medical Services, is readily obtainable.

The rates of pay and allowances are good; the opportunities of post-graduate study are generous, and the work is varied, responsible, and interesting. The gratuities after certain periods of service enable an officer should he so desire to leave the Service with a capital sum large enough to go a long way towards re-establishing himself in civil life, and, further, the knowledge of the world and the comradeship of his fellow officers that he has gained in the Army will be of no small value to him.

New entrants are commissioned in the rank of Lieutenant, and the first six months of service are spent on probation, during which time they undergo, in addition to their Military training at the Royal Army Medical Corps Depôt at Aldershot, a probationary course at the Royal Army Medical College in London in Hygiene, Pathology, Tropical Medicine, Military Surgery, Recruiting, the prevention and treatment of Venereal Disease, and the elements of Army Administration. At the end of this course, and after qualifying at the necessary examinations, their commissions are confirmed, and they take their places in seniority according to the total marks obtained at all examinations up to that date. Officers

Training Corps service with possession of Certificates "A" or "B" (Medical) carries a definite value in marks in this total.

An entrant who is holding or about to hold at the time of the entrance examination an approved whole-time Appointment at a recognised Civil Hospital may be seconded while holding such an appointment up to a maximum period of 12 months. A candidate who has held such an appointment within six months of entry may be granted an antedate up to 12 months in respect of the period the appointment was held. This secondment and antedate counts in all respects as commissioned service, except that pay will not be issued for that period. The Army Council are endeavouring to arrange for all officers who have not themselves obtained a civil hospital appointment to be given a house appointment in a civil hospital for six months, shortly after they receive their commissions.

After a total period of one year's service at home the young officer goes abroad, probably to India, for his first tour of foreign service. Here he gains his first practical experience of tropical disease and tropical hygiene, and possibly his first experience of active service on the frontiers of India. His tour abroad lasts five years, with probably six months' leave home during that time. On returning home the R.A.M.C. officer has the opportunity to decide whether he will remain in the Corps or accept the gratuity of £1000 after seven years' service, and try his fortune in civil life. If he elects to remain, he will, between his eighth and twelfth year of service, undergo a course of post-graduate study at the Royal Army Medical College and the London Hospitals of five months' duration, followed by a course of study of a special subject selected by himself, provided he has shown special aptitude in the post-graduate course or during his previous service. During this period of study he remains on full pay, and the fees for the courses are paid by the State. When qualified in his special subject, the officer becomes entitled to specialist pay at 5s. per day when holding a specialist appointment. After this post-graduate course the officer probably proceeds abroad again and promotion to Major rapidly ensues, and from that time onward the officer receives regular successive increases of pay, and is eligible for additional and charge pay as well. The Directorates of Hygiene and Pathology and the appointment of two serving officers as Consultants in Medicine and Surgery have been instituted and have proved a marked success, all these appointments being of the rank of Colonel or Major-General.

Under these conditions the possibilities for good workers are very great in the Royal Army Medical Corps. There is scope for original research in tropical disease, in preventive medicine, and in bacteriology as well as in the large clinical field open to the specialist in Medicine, Surgery or Gynæcology, in Venereal Disease, and in Ophthalmology. Child welfare is also undertaken systematically by officers of the Royal Army Medical Corps.

At the same time instruction in administration is continuous. The Royal Army Medical Corps is essentially organised for war, and one of the lessons of the Great War was that trained administrators must exist to enable the fullest benefit to be obtained from professional talent. Many appointments carrying administrative responsibility are open to those officers who display capacity for this duty. All officers must be prepared to undertake command and to have a knowledge of Army administration, especially in war.

* Pay Warrant rates as amended by A. O. 196/26 less 7 per cent. from July 1st, 1930, vide A.O. 237 of 1929. The Pay Warrant rates are subject to revision to an extent not exceeding 20 per cent. according to variation in the cost of living. The next revision takes place from July 1st, 1931.

† Rates of allowances vary from time to time and issues are subject to conditions laid down in the Allowance Regulations.

Equally important is the technical training of the Non-commissioned Officers and men of the Corps in such "trades" as Trained Nurse, Nursing Orderly, Masseur, Radiographer, Operating Room Assistant, Laboratory Assistant, Hospital Cook, Dispenser, &c. This training is carried out by the Officers and Nursing Sisters, and opens a large field for those who have ability in lecturing and teaching as well as the power of influencing men.

PROMOTION.

Promotion takes place automatically to Captain after 3½ years, and to Major after 12 years' service, provided the officer is qualified and recommended for promotion. Promotion to the higher ranks is by selection from those senior in the rank below, but special promotion by brevet or otherwise is open to officers of the Royal Army Medical Corps.

ADDITIONAL PAY AND CHARGE PAY FOR R.A.M.C. OFFICERS.

(1) Officer not above the rank of lieutenant-colonel, while acting as specialist in a post considered by the Army Council to merit the grant of additional pay, according to subject or groups of subjects as under.

Operative Surgery, advanced; Medicine; Ophthalmology; Gynæcology and Midwifery; Dermatology and Venereal Disease; Otology, Laryngology, and Rhinology; Radiology; Anæsthetics; Mental Diseases; Hygiene; Pathology; subjects other than above, at the discretion of Our Army Council, 5s. daily.

(2) (*a*) Officer in charge of a hospital.—If the number of quipped beds, as certified by the Deputy Director of Medical ervices, exceeds—

50 beds	2*s.* 6*d.* daily.	300 beds	7*s.* 6*d.* daily.
150 ,,	5*s.* 0*d.* ,,	500 ,,	10*s.* 0*d.* ,,

Officer in charge of a medical or surgical division of a eneral hospital with not less than 300 beds—half the above ates.

	Daily. *s.*	*d.*
) Senior medical officer, Royal Arsenal, not exceeding	10	0
) Officer in command of the depôt, Royal Army Medical Corps	5	0
) The senior officer of the Army Medical Services with an army in the field: A rate to be fixed by the Army Council according to the magnitude of the charge.		
) The officer, if under the substantive rank of colonel, holding the appointment of senior medical officer in a command abroad, or of assistant director of medical services, if the number of soldiers is 1500 or upwards	5	0
) Adjutant R.A.M.C. Depôt	5	0
) Adjutant R.A.M.C. (Territorial Army)	2	6

RETIREMENT AND RETIRED PAY.

The following are the rates of retired pay :—

1. Retired pay will consist of two parts: (*a*) a service lement based on the officer's total service; (*b*) a rank lement for the rank from which the officer retires. An fficer with less than 20 complete years' service will not be ligible to retire voluntarily on service retired pay.

2. The scale will be as follows, subject to the reduction f 7 per cent. referred to below :—

(*a*) Service element.—£15 a year for each completed ear of service as a medical officer.

(*b*) Rank element.—

Rank from which retired.	After completing 1 year's service in the rank.	After completing each additional year's service.	Maximum rank element.
	£	£	£
lajor	12	12	120
ieutenant-Colonel	150	30	240
olonel	290	50	390
lajor-General ..	440	50	540
ieutenant-General	590	50	690

The retired pay of an officer retiring with less than one omplete year's service in the rank from which he retires will e assessed as though he had retired from the rank below.

Maximum rates of retired pay (*a*) and (*b*) together :—

	£		£
aptain and Subaltern ..	300	Colonel	800
lajor	450	Major-General ..	1000
ieutenant-Colonel ..	600	Lieutenant-General	1200

The above rates are those laid down in the Pay Warrant. hey have been reduced by 7 per cent. as from July 1st, 1930, nd are subject to future variation in the ost of living.

3. Officers with seven and less than 20 years' service as edical officers may be permitted to retire with a gratuity in ccordance with the following scale :—

After 7 years' service as a medical officer	£1000
,, 15 ,, ,, ,, ..	£2800
,, 18 ,, ,, ,, ..	£3500

The Army Dental Corps.

This Corps is administered by the Director-General, rmy Medical Services. Regulations for admission o The Army Dental Corps should be obtained from he Under Secretary of State, War Office, and care- ully studied.

OFFICERS: APPOINTMENT AND PROMOTION.

1. Commissions as Lieutenants in the Army Dental Corps ay be given to persons duly qualified under regulations pproved by the Army Council.

2. An officer who is commissioned after holding an pproved whole-time appointment in a recognised civil ental hospital or in the dental department of a recognised ivil general hospital may be granted an antedate covering the period of his appointment, but not exceeding six months, provided that the interval between the termination of the hospital appointment and the date of entry into the Service does not ordinarily exceed six months. The period of such antedate will reckon towards promotion, increase of pay, gratuity or pension.

3. An officer is eligible for promotion to the rank of Captain on completion of three and a half years' service and to the rank of Major on completion of 12 years' service in the Corps, provided he has previously qualified in such manner as may be prescribed by the Army Council.

4. Promotion to the rank of Lieutenant-Colonel and Colonel to fill the establishments laid down from time to time for those ranks is made by selection from those senior in the rank below. Dental officers are also eligible for special promotion by brevet.

PAY.

The following are the rates of pay for officers of the Army Dental Corps.

These rates are 7 per cent. below those shown in the Pay Warrant, 1926, as amended by Army Order 196 of 1926. The latter are subject to revision to an extent not exceeding 20 per cent. according to variation in the cost of living. The next revision takes place on July 1st, 1931.

Lieutenant-Colonel after 3 years' service as such	2	15	10
Colonel	3	2	10

CHARGE PAY.

The officer in charge of the Dental Laboratories, Aldershot, receives charge pay at the rate of 5*s.* a day if holding the rank of Captain, or 2*s.* 6*d.* a day if holding the rank of Major.

ALLOWANCES.

The allowances for officers of the Army Dental Corps are at the same rates as for officers of the Royal Army Medical Corps.

RETIREMENT AND RETIRED PAY OR GRATUITY.

(1) The rates of retired pay will be the same as for officers of the Royal Army Medical Corps.

(2) Voluntary retirement on retired pay will not be allowed until after twenty years' servce.

(3) Earlier retirement on gratuity may be allowed :—

After 8½ years'	service as a Dental Officer,	gratuity of £1000.
,, 15 ,,		,, £2000.
,, 18 ,,		,, £3000.

The aim of the Corps is the prevention of wastage on account of dental disease or dental deficiency, and, to enable this to be carried out, every recruit is inspected by a dental officer immediately after joining and all necessary treatment carried out. The soldier is reinspected at least once a year and the dental efficiency maintained at the best standard possible.

INDIAN MEDICAL SERVICE.

IT is the view of many senior officers in the Service that the period of depression is now passing and that the prospect is again bright for those who are fitted in physique and disposition for a medical career in India.

But the new outlook involves frank acceptance of the Indian reform scheme, the essential of which is increasing participation of Indian-born subjects in the government of the country, although, so long as Europeans are employed in the various departments of the Indian Civil Service, nothing is more certain than that there will and must remain European doctors to attend them. India definitely requires European assistance, not only for the care of the military and civil European population, but for the maintenance in the country of that spirit of modern medicine which has accomplished already such

mighty things, and which day by day is spreading in influence and value.

The Government of India issued a communiqué in 1928 dealing in detail with the reorganisation of the medical services in India. The scheme then sanctioned is based on proposals framed in consultation with local governments. The Indian Medical Service, constituted on the same broad lines as at present, will be retained primarily to meet the needs of the Indian army, and in order to maintain two essential requisites —namely, (1) the necessary minimum war reserve of medical officers, and (2) the provision for European medical attendance on officers and their families. Local governments in India will be required to employ a stated number of I.M.S. officers. It has been calculated that the war reserve to be employed by the civil side should consist of 134 British and 66 Indian officers, the larger proportion of British officers being due to the fact that they cannot be recruited on emergency in India from the ranks of private practitioners. Medical attendance on British personnel, and the requirements of civil administration, for which the Central Government is still responsible, involve the provision of a number of employments termed "residuary," the incumbents of which must be retained permanently in civil employment, so as to ensure the continuance under any circumstances of a skeleton staff to cope with civil requirements. Further details regarding the posts on the civil side were published in the Students' number of 1928.

Rules forming an integral part of the reorganisation scheme have been drawn up to safeguard the varied interests of the Indian army, the provincial governments, and the medical officers themselves (vide THE LANCET, May 19th, 1928, p. 1028). Under these it has now been ruled that as long as any Indian Medical Service Officers in civil employ in 1928 remain, the administrative posts will be filled from among them.

Thus the social effect of Indianisation should not press hardly on the medical service for the reason that European doctors will be chiefly requisitioned in stations with considerable European communities. In these communities the equipment and organisation of hospitals has been steadily improving and men with professional ambition will find positions which will satisfy their aspirations. On the military side the station hospital system has rendered the position of medical officers more independent by making teamwork possible and permitting of specialisation in various departments of medicine and surgery. Lastly, those who join now will have unequalled prospect of advancement in a Service which has been so depleted for 10 or 15 years or more, and the terms of service announced by the Secretary of State for India in 1926 assure conditions of pay, pension, and furlough much superior to those previously offered.

THE NEW REGULATIONS.

Competitive examination remains suspended for the present and admission to the Service is on written application to the India Office. As sound bodily health is a first essential candidates may, if they wish it, undergo a preliminary examination by a Medical Board which meets weekly at the India Office.

Candidates must be under 32 years of age at the time of application, and must possess a qualification registered in Great Britain and Northern Ireland, under the Medical Acts in force at the time of appointment. Arising out of the recommendations of the Lee Commission the Secretary of State for India in Council after consultation with the Government of India has decided that the Indian Medical Service constituted on the same broad lines as in the past shall be retained primarily to meet the needs of the Indian Army. In order to maintain the necessary minimum war reserve of military medical officers, and to provide for European medical attendance for European officers of the Superior Civil Services and their families, local governments will be required to employ a stated number of Indian Medical Service officers. The Government of India will draw on the same Service to meet the requirements of the civil administration for which they are responsible. For the present 237 such posts have been reserved, and including the leave reserve will provide employment for 302 officers. 212 of these officers will be British medical men and 90 Indians. As the proportion of European to Indian civil officers diminishes these figures will be subject to periodical scrutiny, and, if necessary, to revision. It will be a definite condition of service for all future entrants to the Service that they will be liable to serve on either the civil or the military side. All officers are required to perform two years' military duty subsequent to permanent appointment before they can be considered eligible for civil employment. Executive medical officers in both civil and military employment may attend persons unconnected with Government service provided their duty admits of it. On the military side however, the opportunities for private practice are not great. Service during the war as a medical or combatant officer, or in a position usually filled by an officer, counts towards promotion and pension and the commissions of officers who before appointment have obtained certain higher qualifications or have held resident appointments in certain hospitals may be antedated by one year.

RATES OF PAY.

The monthly rates of pay for European officers of non-Asiatic domicile in the Service are as tabulated below. The rupee, it may be remembered, has now been definitely stabilised at 1*s.* 6*d.*

Rank and service in rank.	Basic pay.	Overseas pay.	Year of total service.
	Rs.	Rs.	
Lieut.	500	150	First
		150	Second
		150	Third
Captain :—			
1. During first three years' service as Captain.	650	150	Fourth
		£15	Fifth
		£15	Sixth
2. With more than three and less than six years' service as Captain.	750	£25	Seventh
		£25	Eighth
		£25	Ninth
3. With more than six years' service as Captain.	850	£25	Tenth
		£25	Eleventh
		£30	Twelfth
Major :—			
1. During first three years' service as Major	950		
2. With more than three and less than six years' service as Major	1100		
3. With more than six years' service as Major	1250		
Lieut.-Colonel :—			
1. Until completion of 23 years' total service	1500	£30	Thirteenth and over.
2. During twenty-fourth and twenty-fifth years' total service	1600		
3. After completion of 25 years' total service	1700		
4. When selected for increased pay ..	1850		

Note.—Until the completion of 23 years' total service basic pay is regulated according to rank and service in rank (column 1), which, owing to the system of accelerated promotion, may be in advance of the time-scale of promotion. Overseas pay is regulated solely with reference to length of total service (column 4). In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the I.M.S. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service. The appointment of Director-General, I.M.S., which is held by an I.M.S. officer, carries pay of Rs.3500 per mensem. The appointment of Director of Medical Services in India, carrying pay at Rs.3200 per mensem, may also be held by an officer of the Indian Medical Service.

Initial rates of pay are based on the assumption that the majority of newly appointed officers will be bachelors. Officers on arrival in India will be posted for one year to specially selected stations. Officers in military employment, when in command or second-in-command of the larger station hospitals, receive special allowances. On the civil side there are public health, bacteriological, research, and professorial appointments carrying special enhanced rates. Officers on appointment receive an outfit allowance of £50.

PENSIONS AND ALLOWANCES.

The rates of pensions are as shown in the table below.

There are additional pensions not subject to the above reduction ranging from £65 to £350 per annum for officers who have held high administrative appointments as colonels or major-generals.

Service.	Rates per annum.	Service.	Rates per annum.
After 17 years ..	£400	After 23 years ..	£620
„ 18 „ ..	430	„ 24 „ ..	660
„ 19 „ ..	460	„ 25 „ ..	700
„ 20 „ ..	500	„ 26 „ ..	750
„ 21 „ ..	540	„ 27 „ ..	800
„ 22 „ ..	580		

Note.—The above rates are subject to periodical revision upwards or downwards, to an extent not exceeding 20 per cent. in all, on account of a rise or fall in the cost of living, as compared with the year 1919. A deduction of 4½ per cent. on this account has already been made. Nevertheless the full pension of a lieutenant-colonel cannot be cut below the maximum of £700 under the old rules in the case of officers who entered the service before July 1st, 1920.

Officers on appointment are provided with free passage to India, normally by transport. The wives and families of officers who are married prior to the date of the officers' embarkation on first appointment will also be given free passage to India subject to the payment of messing charges. Officers are granted a certain number of return passages home at Government expense during their career. There are special allowances for officers whilst on study leave.

Further particulars can be obtained on application to the Secretary, Military Department, India Office, Whitehall, London, S.W. 1. Letters should be marked "Recruitment for I.M.S."

ROYAL AIR FORCE MEDICAL SERVICE.

THE Air Council attach great importance to attracting into the service the best type of medical man, since on the capacity of the Medical Service depends in a peculiar degree the safety and efficiency of the Air Force. The duties of a medical officer in the Air Force include not only the prevention and treatment of those ordinary diseases to which the personnel of any fighting service are liable, but the special study of the mental and physical stresses imposed on the airman in diverse circumstances and climates—a new branch of medicine which still provides considerable scope for research.

As promotion to the higher ranks of the Service is by selection from officers who are eligible by reason of length of service, and as a certain proportion of the higher ranks will be reserved for purely professional as opposed to administrative appointments, it will be seen that there are excellent prospects for the young medical officer who exhibits ability and energy in his professional work.

The work to be done, therefore, has a high professional interest which, combined with good rates of pay and allowances, offers a career for medical men which should prove both attractive and interesting. The life is one which is certain to appeal to the man of wide outlook who desires opportunities for travel, sport, and games, and can find interest and enjoyment in aviation.

His duties will, as a matter of course, give him flying experience as a passenger, which is necessary for the proper study of the medical problems of aviation and for gaining first-hand knowledge of the conditions under which his comrades serve.

The establishment will consist partly of permanent and partly of short-service officers.

An officer will on first entry be granted a short-service commission for a period of three years on the active list (which may be extended to five years at the discretion of the Air Council if the officer so wishes on the recommendation of the Director of Medical Services) and of four years in the Reserve of Air Force Officers. Selections for permanent commissions will be made from officers holding short-service commissions, and those who are not selected will be transferred to the Reserve at the expiration of their period of service on the active list.

For those entrants who desire it the prospect of obtaining a permanent commission is approximately an even one. Experience has so far shown that the

* Except for periods of service under Indian administration. For such periods officers receive pay and allowances at rates and subject to conditions authorised from time to time by the Government of India.

† These allowances are issued only when accommodation, fuel and light, rations, and personal attendance are not available in kind. Normally, provision in kind is available for junior officers. "Married" rates of allowances are payable only to married officers who have reached the age of 30 or the rank of Squadron Leader. A colonial allowance is granted in certain commands abroad. The rates and general scheme of allowances are liable to revision as circumstances may require.

officers selected have included the great majority of those desirous of, and suitable for, retention in the service; owing to the fact that the short-service commission with its gratuity after three or five years is in itself an attraction to many entrants who desire to enlarge their experience and outlook from the point of view of subsequently entering private practice, or who, on entry, have not made up their minds to the adoption of a permanent career in the service and subsequently find that they would prefer to return to civil life.

For certain purposes medical officers may be allowed to count as service their time spent in resident appointments in civil hospitals under certain well-defined and generous conditions.

Officers who have been selected for permanent commissions may be permitted to attend for a period not exceeding nine months a post-graduate course in general medicine and surgery, tropical and preventive medicine, and other special subjects. Such permission may be granted at any time when the exigencies of the service permit during the first 16 years of service, and when attending these courses officers will receive full pay and allowances.

New entrants into the Royal Air Force Medical Service will be commissioned as Flying Officers (Medical) and will be eligible for promotion to the rank of Flight Lieutenant (Medical) after two years' service. Officers selected for permanent commissions will normally be promoted to the rank of Squadron Leader after ten years' total service. Accelerated promotion may be granted in a limited number of cases to officers who show exceptional ability after the completion of eight years' service. Promotion within establishment to the rank of Wing Commander will be by selection at any period after 16 years' total service, and that of Group Captain by selection at any period after 22 years' service.

Certain posts in these ranks are reserved for officers fully employed in professional work, such as surgery, pathology, ophthalmology, &c., numbering at present six in all. The number of these posts will be limited only by the needs of the service and by the necessity of observing a similar proportion between the number of reserved posts and the officers from whom they can be filled, as exists between the total number of higher ranks and the remainder of the medical service. Selections for these reserved posts will be made only from officers professionally qualified to hold them. Officers filling the reserved posts will be eligible for selection to the administrative appointments of their rank, and to the highest administrative appointments.

There will be no competitive examination on entry; candidates must be under 28 years of age, be British subjects, the sons of British subjects, and of pure European descent, be nominated by the dean of a recognised medical school or teaching hospital, and will be interviewed personally by the Director of Medical Services, Royal Air Force, before acceptance. Each candidate must produce :—

1. Birth certificate. 2. Medical registration certificate. 3. A declaration containing the following information: (*a*) Age and place of birth. (*b*) That he is a British subject, the son of British subjects, and of pure European descent. (*c*) That he is ready to engage for general service at home or abroad as required. (*d*) The qualifications he is possessed of, and what medical or other appointments he has held (if any). (*e*) That he is willing to fly as a passenger whenever called upon to do so.

Each candidate will be required, before acceptance, to pass a medical examination to ensure that he labours under no constitutional or mental disease or diseases or weakness, nor any imperfection or disability which may interfere with the efficient discharge of the duties of a medical officer in any climate, in peace or war.

On appointment entrants will undergo an initial course of eight weeks, during which they will be given instruction in the special medical aspects of aviation, the organisation and administration of the Royal Air Force, and the general and special duties to be performed by officers in the Medical Branch.

In order to avoid the necessity for further examinations the position of entrants in order of seniority in the Air Force List will be determined at the end of the initial course by a system of marking and reports on the actual work done during their instruction.

UNIFORM AND EQUIPMENT.

Medical officers are required to provide themselves with the uniform, service dress and mess dress of their rank and with the distinguishing badges of the Royal Air Force Medical Branch. The provision of full dress is entirely optional at present. An allowance of £5 towards the cost of uniform is made on joining to candidates who have not had previous commissioned service in H.M. Forces.

EMOLUMENTS.

The emoluments of medical officers of the Royal Air Force are given in outline above. The standard rates of pay and retired pay were drawn up on the basis of the high cost of living in 1919, and 20 per cent. on each of the standard rates is detachable and subject to alteration upwards or downwards in relation to the increase or decrease of the cost of living above or below the cost in July, 1919. Under this provision the current rates in force from July 1st, 1930 represent a reduction of approximately 7 per cent. on the standard rates. The next revision will take effect from July 1st, 1931.

Retired Pay.

The minimum period of service qualifying for retirement on retired pay is 20 years. Standard rates of retired pay are as follows :—

AIR OFFICERS.

Air Vice-Marshal ..	.. £790 to £1010 per annum.
Air Commodore ..	.. £650 „ £950 „ „

The maximum standard rates of retired pay and the compulsory retiring ages for the several ranks are :—

Rank.	Yearly rate of retired pay.	Compulsory retiring age.
	£	
Air Vice-Marshal ..	1010	60
Air Commodore ..	950	57
Group Captain.. ..	900	55
Wing Commander ..	600	51
Squadron Leader ..	500	48

OFFICERS BELOW AIR RANK.

Age on retirement.	Standard yearly rate of retired pay.	Years of service.	Addition for each extra year of service.*	Deduction for each deficient year of service.*
	£		£	£
40	300	17	15	15
41	337	17	15	15
42	375	18	15	15
43	412	18	15	15
44	450	19	15	15
45	487	19	15	15

52	720	23	22	15
53	742	23	22	15
54	765	24	22	15
55	790	24	22	15

* Limited to five years.

Gratuities.—A permanent officer allowed to retire before having qualified for retired pay may be granted a gratuity provided he has not less than ten years' commissioned service, namely :—

£1500 if he has 10 but less than 15 years' commissioned service
£2500 „ „ 15 or more than 15 „ „ „

Short-service officers will be eligible on passing to ne Reserve for gratuities on the following scale: 100 for each of the first two complete years of service, 150 for each of the third and fourth complete years, nd £200 for the fifth complete year; that is:—

For three years' service on the active list	.. £350
For five " " " " "	.. £700

hese gratuities will not be payable to officers ranted permanent commissions, but their service n a short-service commission will count towards etired pay.

COLONIAL MEDICAL SERVICE.

In the self-governing Dominions (Canada, Australia, lew Zealand, the Union of South Africa, the Irish ree State, and Newfoundland), and territories under neir control, such as Papua and the Cook Islands and n the self-governing colony of Southern Rhodesia, nedical appointments are made concerning which nformation can be obtained from the High Comnissioners or Agents-General in London; application or appointments in North Borneo should be made to ne British North Borneo Company, 17, St. Helen's-lace, E.C.; appointments in Sarawak are in the ands of H.H. the Rajah. Much valuable information ill be found in the "Professional Handbook," art II., issued by the Oversea Settlement Office, axton House, Tothill-street, London, S.W. 1, price 9*d*.

As a general rule, each Colony or Protectorate has s own public service distinct from that of every ther; and it is usually only the higher officers who re transferred by the Secretary of State from one olony to another. There are three exceptions to nis rule: (*a*) The West African Medical Staff, which erves Nigeria, the Gold Coast, Sierra Leone, and the ambia, is one service. (*b*) The East African Medical ervice, which serves Kenya, Uganda, Zanzibar, yasaland, Somaliland, and the Tanganyika Terriory, is one service. (*c*) In practice the medical serices of the Straits Settlements and the Malay States nay be regarded as one, as the officers may be and equently are transferred from the Colony to the tates or vice versa; the two services are now called ne Malayan Medical Service.

The Colonies, Protectorates, and Mandated Territories to which medical officers are appointed by the ecretary of State for the Colonies are (*a*) the West frican—viz., Nigeria, the Gold Coast, Sierra Leone, nd the Gambia, with the Mandated Territories of ogoland and the Cameroons; (*b*) the East African—iz., the Kenya Colony and Protectorate, Uganda, yasaland, Somaliland, and Zanzibar Protectorates, ne Tanganyika Territory, and Northern Rhodesia;) the Eastern—viz., Ceylon, the Straits Settlements nd Malay States, Hong-Kong, Mauritius, and eychelles; (*d*) the West Indian—viz., Jamaica, rinidad, the Windward Islands, the Leeward slands, Barbados, and the Bahamas; (*e*) Fiji and ne Western Pacific, Cyprus, Gibraltar, St. Helena, ritish Guiana, British Honduras, Bermuda, and the alkland Islands; and (*f*) Palestine.

In Ceylon, Mauritius, Jamaica, Barbados, the ahamas, and Bermuda vacancies are practically lways filled locally by the appointment of qualified ative candidates, or—in the case of some of the igher posts—by transfer from other Colonies. n the Bechuanaland Protectorate, Basutoland, and waziland appointments are usually filled locally. ppointments in Malta are all filled locally. In ddition, certain medical appointments in the service f the Government of Iraq are filled upon the recomendation of the Secretary of State. Vacancies ccur most regularly and frequently in the West frican Medical Staff, the East African Medical ervice, and the Straits Settlements and Malay States.

All applicants for medical appointments in the gift f the Secretary of State for the Colonies should be nder 35 years of age, and must be doubly qualified; preference will be given to those who have held hospital appointments as house physicians and house surgeons; testimonials to character and professional competence will be required, and every officer before being definitely appointed will be medically examined by one of the consulting physicians of the Colonial Office: Dr. P. H. Manson-Bahr, D.S.O., F.R.C.P., 9, Weymouth-street, Portland-place, W.1, and Dr. A. E. Horn, C.M.G., 14, Wimpole-street, W. 1; Dr. H. C. Drury, 48, Fitzwilliam-square, Dublin; Dr. Foster Coates, 22, College-gardens, Belfast; and Lieut.-Colonel Glen Liston, C.I.E., I.M.S., 33, Comely Bank, Edinburgh, and Dr. G. E. H. Le Fanu, 33, Rodney-street, Liverpool. Applications for such appointments must be addressed to the Private Secretary (Appointments), Colonial Office, 2, Richmond-terrace, Whitehall, S.W.1.

Instruction in Tropical Medicine.—Every candidate selected for appointment will, unless the Secretary of State decides otherwise, be required to undergo a course of instruction at the London School of Hygiene and Tropical Medicine, Endsleigh-gardens, W.C.1, the Liverpool School of Tropical Medicine, Liverpool University, or at Edinburgh University. The cost of tuition will be borne by the Government, but candidates must make their own arrangements for board and lodging; an allowance of £25 a month will be paid to them monthly in arrear while they are under instruction. Payment of the allowance will be made subject to the candidate signing an agreement by which he is bound to refund it (1) if he declines to accept an appointment in any of the Colonies for which he may be selected; (2) if he fails to obtain a certificate or diploma; (3) if he leaves the Service within three years for any reason other than mental or physical infirmity not caused by his own misconduct.

West African Medical Staff.

Applicants for appointment as medical officers or medical officers of health in the West African Medical Staff (the higher grades will usually be filled by promotion from the lower) must be British subjects of European parentage and between 23 and 35 years of age; preference is given to candidates who are over 25 years of age. Applicants must possess a complete double qualification, and must be on the Medical Register. Passages for wives and children are not provided by the Government, and houses for the wives of junior medical officers are rarely available. Officers are not usually allowed to take their wives and young children out with them until they have acquired experience of the local conditions and have obtained the sanction of the Governor. When an officer has obtained permission to be accompanied by his wife a grant of one-half the cost of his wife's passage to and from West Africa is made subject to certain conditions.

Candidates are allowed to express a preference for any particular Colony, and their wishes in this respect will be borne in mind and met as far as possible, but they are liable to be posted in the first instance, or transferred afterwards if necessary to any other West African Colony at the discretion of the Secretary of State. Candidates who wish to be posted to Nigeria will probably find it useful to be able to ride. Transfers from one Colony to another will be made as seldom as possible. Candidates should on no account apply for, or accept, a West African appointment in the expectation of ultimately being transferred.

Those transferred to pensionable Crown appointments elsewhere than in West Africa do not forfeit their claim to pension in respect of their West African service on final retirement, provided that they have been members of the staff for at least 12 months. Every officer selected for appointment is required to have himself revaccinated before proceeding to West Africa, unless one of the medical advisers of the Colonial Office certifies that this is unnecessary.

Leave of Absence.—European officers in West Africa may be granted vacation leave on full salary

not exceeding in all one week's leave in the United Kingdom for every completed calendar month of total residential service in West Africa, plus the time necessarily taken on the journey to the United Kingdom, and, if the officer is returning to West Africa for further service, the time necessarily taken on the journey from the United Kingdom to the Colony. Vacation leave may be granted without any special grounds after 18 consecutive calendar months of residential service in West Africa. An officer will not be required to serve a tour of more than 24 consecutive calendar months' residential service except in special circumstances; and the Governor may grant vacation leave to any officer at any time after he has completed 12 consecutive calendar months' residential service within the above limits, the actual length of each officer's tour will be at the discretion of the Governor. Vacation leave on full salary may also be granted to an officer if he is invalided from West Africa after less than 12 consecutive calendar months' residential service, and sick leave on full salary may be granted for any period not exceeding six calendar months.

Appointments and Salaries.—Medical officers for the West African Colonies and Protectorates—namely, the Gambia, Sierra Leone, the Gold Coast (including Ashanti and the Northern Territories), and Nigeria (Southern and Northern Provinces)—are selected by the Secretary of State for the Colonies, and are on one list for employment and promotion. The grades and emoluments of the Staff are at present as follows:—

The Director of the Medical and Sanitary Service, Nigeria, receives a salary of £1800 a year, with a duty allowance at the rate of £360 a year. The Director of Medical and Sanitary Service in the Gold Coast receives a salary of £1600 a year, with a duty allowance at the rate of £320 a year. The Director of Medical and Sanitary Service in Sierra Leone receives a salary of £1400 a year, with a duty allowance at the rate of £280 a year. The Deputy Director of Medical and Health Service, Nigeria, and the Deputy Director of Health Service, Nigeria, receive salaries of £1500 a year, with duty allowances at the rate of £300 a year. The Deputy Director of Medical and Health Service, Gold Coast, the Deputy Director of Health Service, Gold Coast, and the Assistant Directors of Medical and Health Service, Nigeria, receive salaries of £1400 a year, with duty allowances at the rate of £280 a year. Assistant Directors Medical Service: There are six appointments on this grade, four in Nigeria, two in the Gold Coast. The salary is at the rate of £1300 a year, with duty allowance at the rate of £260 a year. The Assistant Director of Health Service, Nigeria, the Assistant Director of Health Service in the Gold Coast, and the Deputy Director of Health Service in Sierra Leone receive salaries at the rate of £1300 a year, with duty allowances at the rate of £260 a year. Specialists: The number of these appointments is not fixed, officers of outstanding professional merit being eligible for appointment. The salary is at the rate of £1300 a year, with duty allowance at the rate of £260 a year. After five years' approved service as such, the specialist officer is eligible to receive a salary at the rate of £1400 a year, with duty allowance at the rate of £280 a year. There are at present five officers appointed specialists in Nigeria, three in the Gold Coast, and one in Sierra Leone. Senior Medical Officer: There are twenty appointments of this grade, with salary at the rate of £1000 a year, rising by annual increments of £50 to £1150 a year, and seniority allowance at the rate of £100 a year. The Senior Medical Officer, Gambia, is allowed "staff pay" of £150 a year, in addition to duty allowance, but he is debarred from private practice. Senior Health Officer: There are eight appointments of this grade, with salary at the rate of £1050 a year, rising by annual increments of £50 to £1200 a year, and a duty allowance at the rate of £210 a year. Possession of the Diploma in Public Health is usually required for appointment to this grade. Special facilities are granted to study for the diploma during leave. Medical Officers of Health: There are at present 29 appointments of this grade. The salary scale is the same as that of Medical Officers, except that Medical Officers of Health are granted an initial salary at the rate of £800 a year, together with seniority allowance at the rate of £72 a year and staff pay at the rate of £150 a year, half of which is payable during leave. After three years' service on the maximum of the scale, viz., £960 a year, and on undergoing an approved course of study, Medical Officers of Health are eligible, if unpromoted, subject to the recommendation of the Governor, to be placed on the scale £1000 a year rising by annual increments £50 to £1150 a year, together with seniority allowance the rate of £100 a year and staff pay as before. The holde of these appointments are not allowed private practic Candidates selected for service as Medical Officers of Heal must obtain the Diploma in Tropical Medicine and Hygie of Cambridge, London, or Liverpool as a condition of appoin ment, or must be in possession of the Diploma in Publ Health. They are appointed subject to the condition tha if after a period of service in West Africa they are consider unsuitable to serve in that capacity, they may be called up to transfer to the medical side. In such cases the office are given the rate of salary which they would have reach if they had been appointed to be Medical Officers instead Medical Officers of Health in the first instance. Medic Officer: The salary attached to this grade is at the rate of £6 a year, rising by annual increments of £30 to £720 a yea Then, if confirmed in the appointment, £720 a year, rising annual increments of £40 to £960, with seniority allowance the rate of £72 a year. Before passing £800, medical office are required to take a special course of study for three month If they obtain satisfactory certificates at the end of t course they draw their further increments up to £960 a yea

A medical officer who has served for three years the maximum salary of this scale (£960) witho obtaining promotion is eligible, if recommended the Governor, to be placed on the scale £1000–£5 £1150, with £100 seniority allowance (as for Seni Medical Officers).

Special Appointments.—The Director of the Medic Research Institute, Lagos, and the Director the Medical Research Institute, Accra, receive a sala of £1300 a year, with a duty allowance of £260 year, rising after five years' approved service to salary at the rate of £1400 a year and duty allowan at the rate of £280 a year. There are a number appointments for pathologists and bacteriologists Nigeria, the Gold Coast, and Sierra Leone. The sala and other conditions attached to these posts are simil to those of Medical Officers of Health. Duty allo ances, seniority allowance, and staff pay are n pensionable emoluments.

Increments.—Increments to salaries are payab only when the service of an officer during the peri of employment qualifying for increment is approve

Payment of Salaries.—Information as to the pa ment of officers' salaries or of monthly remittances persons in England may be obtained from the Crow Agents for the Colonies, 4, Millbank, S.W. 1. allowances are paid locally.

All officers of the staff, except directors, depu directors, assistant directors, senior sanitary office medical officers of health, research officers, and few other officers holding special appointmen are at present allowed to take private practi provided that it does not interfere with the faith and efficient performance of their official duties, b it is within the power of the Governor to withdr or suspend the privilege in such places and such periods as he may consider desirable. Priva practice does not exist at many stations, and guarantee can be given that an officer will be post to a station in which he will be able to practi privately. As a general rule, and subject to t exigencies of the service, stations where there private practice are allocated to senior members the Staff.

Pensions and Gratuities.—Pensions and gratuities retirement are granted in accordance with the law a regulations of each individual Colony.

African Medical Officers.—In addition to t membership of the West African Medical Staff, whi is limited to British subjects of European parenta there are a number of Government appointments f African medical officers in the West African Coloni These appointments carry a salary on the scale £50 20–£600, and there is a higher scale, £600–30–£7 In addition, in Nigeria and on the Gold Coast, arran ments have been made for the employment of a f young African medical men temporarily on the h pital staffs, with a view to appointment to the Gover ment service later, if suitable. In such cases a sala of £400 a year is paid.

East African Medical Service.

The Medical staffs of the Kenya Colony and Protectorate, the Uganda, Nyasaland, Somaliland, and Zanzibar Protectorates, and the Tanganyika Territory form one service, the members of which are liable to be posted or transferred to any of the Dependencies as the exigencies of the service may require. The preferences of individual officers are, however, taken into consideration as far as possible.

Selected candidates are appointed as medical officers on probation in the first instance for two years, at the end of which period their appointments are made permanent if their service has been satisfactory. Medical officers (but not health officers) are permitted to take private practice at some stations on the understanding that they give precedence to their official duties. It must be understood that additions to their income from this source are not likely to be substantial, and that the privilege is liable to withdrawal at any time.

Officers are provided with quarters free of rent or the Government may provide temporary accommodation, or an allowance in lieu of quarters may be paid. The salary of a medical or sanitation officer is £600 per annum, rising by annual increments of £30 to £840, and thence by increments of £40 to £920, subject to an efficiency bar at £840. Senior medical officers and senior sanitation officers are paid on the scale £1000 by annual increments of £50 to £1100. Officers who possess the Diploma in Public Health on entering, or who acquire it while in the Service, receive two special increments in the scale.

Officers of the East African Medical Service are permitted to retire with gratuity, if they wish, instead of waiting to retire on pension as follows: (*a*) After nine years' service, of which at least six must have been spent in East Africa, £1000; (*b*) after 12 years' service, of which at least eight must have been spent in East Africa, £1250. If an officer elects to retire with gratuity he thereby forgoes all claim to pension.

The grades and salaries (apart from ordinary medical and sanitation officers) in the medical departments are as follows:—

Kenya.—Director of Medical and Sanitary Services, £1500; Deputy Director of Medical Service, £1200; Deputy Director of Sanitary Service, £1200; Deputy Director of Laboratory Service, £1200.

Uganda.—As Kenya.

Tanganyika Territory.—As Kenya.

Nyasaland.—Director of Medical and Sanitary Services, £1300; Medical Entomologist, £1000–£50–£1100.

Zanzibar.—Director of Medical and Sanitary Services, £1400; Deputy Director of Sanitary Service, £1200; Resident Surgical Officer, £1000–£50–£1100.

Somaliland.—Principal Medical Officer, £1000–£50–£1100.

There are also the following posts:—Resident Surgical Officers (Kenya and Uganda), £1200; Specialist Officer, Sleeping Sickness (Uganda), £1150; Medical Superintendent and Principal of Medical School, Mulago Hospital (Uganda), £1150; Sleeping Sickness Officer (Tanganyika Territory), £1000–£50–£1100; Senior Bacteriologists (Kenya and Uganda), £1000–£50–£1100.

Health officers are selected from the ranks of medical officers as occasion arises.

Asia.

Straits Settlements and Federated Malay States.—European medical officers are appointed on the following scale of salaries: $500 per mensem, rising to $550 per mensem during three years' probation; then, if they are placed on the pensionable establishment, rising to $575 per mensem, and thence by annual increments of $25 per mensem to $800 per mensem, with a strict efficiency bar at $600 per mensem. Officers possessing the D.P.H. receive an additional allowance (non-pensionable) of $100 per mensem.

Above the concluding figure of $800 per mensem there are certain higher appointments, as follows: Principal Civil Medical Officer, Straits Settlements, and Principal Medical Officer, Federated Malay States, $1200 per mensem each; Director, Institute for Medical Research, Federated Malay States, Chief Health Officer, Federated Malay States, and Principal, Medical College, Straits Settlements, $1100 per mensem each; 12 posts at $1050 per mensem; and 29 posts at $850 per mensem, rising annually by $30 to $1000 per mensem.

The following temporary allowances are at present paid to all officers recruited from Europe in the Government Services of the Straits Settlements and Federated Malay States: unmarried officers, 10 per cent. of salary; married officers, 20 per cent. of salary. Private practice by Government medical officers is not allowed, but consultation work with another practitioner is permitted. Information about general conditions in Malaya is obtainable from the Malayan Information Agency, 57, Charing Cross, S.W. 1.

Seychelles.—The chief medical officer receives Rs.8000 per annum and the resident surgeon Rs.6500 per annum. There are two assistant Government medical officers, one receiving Rs.6500, the other Rs.4500 per annum.

Hong-Kong.—The present establishment of the medical department is: director of medical and sanitary services £1500–£50–£1800; deputy director £1300–£50–£1400; senior medical officer, £1200–£40–£1280; senior health officer, £920–£40–£1280; five health officers, £860–£40–£1220; health officer of port, £920–£40–£1280; second health officer of port, £860–£40–£1220; eight medical officers, £700–£40–£1180; malarial research officer, £1280; bacteriologist, £920–£40–£1280; assistant bacteriologist, £860–£40–£1220; radiologist, £860–£40–£1220. The currency of Hong-Kong is based on the silver dollar. For purposes of local payment salaries fixed in sterling are converted into dollars at the current rate of exchange. If quarters are provided rent is charged. In certain instances a rent allowance is paid instead.

America.

British Guiana.—There are the following posts in the medical service of the Colony: one surgeon-general, £1000–£1200 per annum, with consulting practice; one medical officer of health, £900; ophthalmologist, £700; one bacteriologist and pathologist, £700; 30 medical officers at £500–£25–£700. Most of the senior posts in institutions carry duty allowances (varying from £50 to £300 per annum) and quarters.

Trinidad and Tobago.—In Trinidad and Tobago there are about 40 appointments. Government medical officers receive salary at the rate of £400 per annum, rising by annual increments of £25 to £600. An officer appointed to a district receives, in addition to his salary, a travelling allowance varying from £100 per annum in a normal district to £150 per annum, and is allowed private practice, the value of which is estimated at from £50 to £800 per annum. Officers employed in institution work receive a duty allowance varying from £50 to £300. Medical officers having completed 10 years' resident service are pensionable at the age of 55.

Windward Islands (Grenada, St. Lucia, St. Vincent). There are over 25 appointments. The chief medical officer, Grenada, receives £750, and also an allowance of £50 as bacteriologist. The chief medical officer, St. Lucia, receives £600–£700 plus forage and subsistence allowances; the post is pensionable, but private practice is not allowed except as a consultant. The chief medical officer, St. Vincent, receives £500–£600, with free quarters valued at £40. Most of the remaining appointments are district appointments with the right to private practice attached; the salaries paid by Government are, in Grenada, on the scale £500–£600, in St. Lucia, £400–£500, in St. Vincent, £400–£450. The Governor has the power to transfer a medical officer from one island to another. Appointments are pensionable.

Leeward Islands (Antigua, St. Christopher and Nevis, Dominica, Montserrat, Virgin Islands).—The

appointments are similar in number and character to those in the Windward Islands, and are pensionable. An officer when first sent out is not appointed to a particular island but to the service of the Leeward Islands, with a salary of £350, and is later appointed to a definite district at a salary varying from £312 to £400–£25–£450, and the Governor decides as to the district which is to be allotted to him, according to station. He is liable to be transferred at the Governor's discretion to any medical district in the Leeward Islands. The medical officers, except in St. Christopher and Nevis, receive fees for successful vaccinations, post-mortem examinations, evidence at courts of justice, certificates of lunacy, and, in the larger islands, for burial certificates. They are also, as a rule, allowed private practice. The chief medical officer, St. Christopher and Nevis, receives £700–£25–£750, but is not allowed private practice, except as a consultant.

British Honduras.—There are seven medical appointments (besides the post of principal medical officer) at a salary of $2430 per annum with increments of $120 to $3150. Unless they already possess a diploma of public health, medical officers are liable to be required, before they join the colony, to undergo a course of instruction at a laboratory of public health or analogous institution. The value of the dollar is the same as that of the United States dollar. The appointments are pensionable.

Other Overseas Appointments.

Fiji.—The Chief Medical Officer receives £1000–£50–£1100, with free quarters, partly furnished; the Medical Superintendent, Colonial War Memorial Hospital, £800–£25–£1000, and free quarters; the Medical Superintendent, Leper Asylum, £700–£50–£950, with completely furnished quarters and one servant; the Medical Officer of Health, £750–£25–£900, no quarters provided; Assistant Medical Superintendent, Colonial War Memorial Hospital, £500–£25–£725. There are 14 District Medical Officers who receive £500–£25–£725, with partly furnished quarters or £50 house allowance (at the option of the Government) and duty allowance of £50 per annum in districts where no private practice exists. In certain districts house allowances or car allowances are granted. In others a medical officer is provided with a launch or boat. District Medical Officers are allowed private practice on the understanding that their official duties are not neglected. In four districts the Medical Officer is also District Commissioner and receives an additional allowance of from £175 to £275 and free partly furnished quarters. In most districts there is private practice, the value of which has been estimated at from £100 to £600 a year.

Western Pacific High Commission.—The staff in the British Solomon Islands Protectorate consists of a Senior Medical Officer (£700–£50–£900), one Assistant Medical Officer (£550–£650), and one Travelling Medical Officer (£550–£650). Partly furnished quarters are provided and a local allowance of £50 per annum is paid to the Senior Medical Officer and the Assistant Medical Officer. A local allowance of £50, consolidated travelling and subsistence allowance £200, and partly furnished quarters are provided for the Travelling Medical Officer.

In the Gilbert and Ellice Islands Colony there is a Senior Medical Officer (£650–£750), with partly furnished quarters, and one Medical Officer (£600–£25–£650), with partly furnished quarters or house allowance. There is hardly any private practice in the British Solomon Islands Protectorate or the Gilbert and Ellice Islands Colony.

Cyprus.—There is a chief medical officer paid at the rate of £750, rising by annual increments of £25 to £850, and three district medical officers paid at the rate of £500 a year, rising by annual increments of £20 to £600 a year, all enjoying private practice (except the chief medical officer and one of the district medical officers, who are allowed consulting practice only). There is also a post of consulting surgeon £400–£20–£600 a year, with consulting practice. There is also a medical officer of health on £600 rising by £20 increments to £750 without private practice, and a specialist in venereal diseases with a salary of £700 a year and consulting practice; these are the only medical appointments open to British candidates.

Gibraltar.—There is a surgeon of the Colonial Hospital receiving £730, and private practice. There are also two assistant surgeons with a salary of £60 for 3 years and thereafter £650–£25–£700 per annum who are allowed private consulting practice only. Free quarters, unfurnished, are provided for all three officers.

St. Helena.—The colonial surgeon at present receives £550 per annum, fees estimated at about £2 a year, and £30 horse allowance. The assistant colonial surgeon at present receives £500 a year and £30 horse allowance. Private practice is allowed, and such practice, together with the duties of non-Government appointments, is divided between the colonial surgeon and the assistant colonial surgeon in a proportion approved by the Governor. The value of private practice and appointments is estimated at about £536 a year.

Falkland Islands.—There are two appointments. The principal medical officer is paid at the rate of £800 per annum, with free furnished quarters and £200 in lieu of private practice. The medical officer is paid at the rate of £500 per annum, with an allowance of £50 per annum in lieu of quarters, and is allowed private practice. The offices are pensionable.

Palestine.[1]—The grades and salaries of higher appointments in the Department of Health are: Director, £P.1200, plus £P.200 expatriation allowance; Deputy Director, £P.900–50–£P.1100, plus £P.150 expatriation allowance. Assistant Director (Laboratories), Specialist Surgeon,[2] and five Senior Medical Officers, £P.750–25–950, plus £P.100 expatriation allowance. One Senior Medical Officer and Government Analyst, £P.550–25–750, plus £P.100 expatriation allowance. The remainder of the staff is recruited locally. A temporary and variable cost-of-living allowance is at present payable in addition to the salaries stated above.

Iraq.—The grades and salaries of the principal appointments in the Department of Health are: Inspector-General of Health, Rs.1800–100–2800 a month; Health Specialists, Directors of Hospitals and Institutes, Chief Medical Officers in Mosul and Kirkuk, Medical Officers of Health in Baghdad and Basra, Rs.1500–75–1800–100–2300 a month; Medical Officers, Rs.1200–75–1800 a month. Posts in the service of the Government of Iraq are not pensionable. Every officer (unless serving on a 3 years' contract) is required to contribute one-twelfth of his pay to a provident fund, to which the Government makes a contribution equal to one-sixth of his pay.

Leave and Pensions.

Leave and Passages.—Leave of absence in East Africa. The normal tour of service is 20 to 30 months (less in Somaliland) after which leave is granted with full salary for 2½ to 3½ days, according to the districts in which the officer has served, for each month of service, plus the period of the voyage to England. If the officer is returning to East Africa for further service, he receives a further similar amount of leave, plus the period of the voyage to East Africa. Extensions of leave with full salary are given in case of sickness or in the case of officers attending approved courses of instruction. In addition to the above, local leave may be granted up to 14 days a year. Officers serving in Northern Rhodesia are allowed four (or two) days' leave in respect of each month of service. Free first-class passages are provided for the officer on first appoint-

[1] £P.1 = £1 sterling.

[2] A certain amount of private practice is allowed.

ent and on leave, and in certain cases assistance wards family passages is given.

In Malaya eight months' full-pay leave is normally anted: (*a*) after a tour of four years' resident rvice during the first eight years of resident service;) after a tour of three years' resident service during ie next six years of resident service; (*c*) after a ur of two and a half years' resident service after years' resident service. Additional leave on lf-pay may be granted on special grounds. Officers e provided with free passages on first appointment r themselves and their families (i.e., wife and ildren up to five persons, inclusive of the officer). nder temporary regulations at present in force, ee return passages on leave to all officers (and their ives and their children under the age of 10) irrespec- ve of salary.

In other Colonies outside Tropical Africa, subject the necessities of the service, leave of absence on lf salary may be granted after a period of three ars' resident service without any special grounds. may be given before the expiration of that period in se of serious indisposition, or of urgent private fairs. In the absence of special grounds, the leave ust not exceed one-sixth of the officer's resident rvice; on special grounds it may exceed that period six months. In addition to the above, vacation ave on full pay may be granted, if no inconvenience expense is caused thereby, not exceeding three onths[3] in any two years. British Guiana, Jamaica, d Trinidad officers are allowed to accumulate ll-pay leave at the rate of six weeks for each year's rvice up to six months, exclusive of the period of e voyages to and fro, and no leave of absence ay (except in very special circumstances) exceed x months in all unless the officer has served for e years or more without leave, in which case two onths on half-pay may be taken in addition to x months' full-pay leave.

On first appointment an officer will, except in e case of a few Colonies possessing Representative semblies, be provided by the Crown Agents for the lonies with free passages to the Colony for himself d his wife and children, if any, not exceeding four rsons besides himself. The officer so appointed ll be required to execute an agreement binding him repay the cost of the passage or passages so obtained the event of his leaving the Government service thin three years. An officer taking leave out of e Colony has in most cases to provide his own ssages.

Pensions.—East Africa.—Officers on the pensionable establishment may retire (or be retired by e Government) on attaining the age of 50 years; t they may be retained in the service, with their n consent, for such further period as the Govern- ent may recommend. Earlier retirement in the ent of ill-health is also provided for. Pension computed at one-four hundred and eightieth of nsionable emoluments—i.e., salary and value of free arters [4] in respect of each month's pensionable rvice—at the time of retirement, subject to an erage of emoluments for the last three years before irement instead of the actual emoluments at the ne of retirement being taken as the basis for lculation in certain circumstances.

Other Colonies.—In most of the other Colonies an ficer holding a pensionable appointment may be owed in the case of ill-health to retire on a pension ter ten full years' resident service; otherwise he ust have attained the age of 55. For ten full years' sident service fifteen-sixtieths of the average annual lary of the retiring officer's fixed appointments for ree years prior to retirement may be awarded, to hich one-sixtieth may be added for each additional ar's service; but no addition will be made in respect of any service beyond 35 years. For pension purposes absence on vacation leave counts as full service, and leave on half-pay as half service. In a few cases the retiring age is 60 and the pension after ten years' service is ten-sixtieths instead of fifteen. In the Straits Settlements and Malay States, an officer may, with the consent of Government, retire at age 50. Pensions are calculated on a basis of length of service in months instead of years.

[3] Or, in the case of Fiji and the Western Pacific and the Falkland Islands 4½ months in any three years.

[4] The value of free quarters for pension purposes is taken as 10 per cent. of the minimum salary of the grade in which an officer is serving at the time of retirement, subject to a maximum of £150.

Sudan Medical Service.

This Service is responsible for carrying out civil, medical, and public health duties in the Sudan.

The staff consists of: (*a*) A Director, pay £E.1500–£E.2000. (*b*) A Senior Physician and a Senior Surgeon to the Khartoum and Omdurman Civil Hospitals, each with a pay of £E.1200–£E.1750. (*c*) An Assistant Director. (*d*) Medical Officer of Health, Khartoum Province, at a special rate of pay. (*e*) 31 British "Senior Medical Inspectors" and "Medical Inspectors" whose pay commences at £E.720 and rises, subject to the recommendation of the Director, by five biennial increases to £E.1080, and after 13 years' service to £E.1200. The Senior Medical Inspectors are eligible, by selection, for the four senior posts. All Medical Inspectors are appointed, in the first place, on probation for two years, and if at the end of that time they are accepted for permanent service under the Sudan Government, the first increase of pay is subject to their passing an examination in Arabic.

In addition to the above there are (*f*) a number of Medical Officers trained at one of the Syrian Medical Schools, besides (*g*) Sudanese Medical Officers trained at the School of Medicine at Khartoum. There are several native (*h*) Assistant Medical Officers, who have been given a purely practical training in one of the larger hospitals in the Sudan.

Amongst the attractions of the Service are: The great variety of the work met with among many different races of the Sudan; *leave* of 90 days, generally granted every year after the first 18 months of service; *study-leave*, which may be given for some definite purpose, whilst two years towards pensionable service may be granted to those who have special qualifications and experience. The pension for Medical Inspectors who retire after 20 years' service is not less than £E.500 a year. If, however, he serves for a longer period, or is appointed to one of the higher posts, he will receive a larger pension. Private practice is allowed, but is limited to a few of the larger towns, and may be carried on so long as it does not interfere, in any way, with official duties. These duties include acting as consultant to the principal hospitals and the supervision of medical and public health work, the inspection of schools, the examination of candidates for Government service and pension, and the training of Assistant Medical Officers and native Sanitary Overseers. The Khartoum Medical School is staffed mainly by members of the Medical Service, who receive additional remuneration for their work as teachers. A Registrar of the Medical School is also selected from the Service, who receives £E.250 a year extra pay.

The country is developing rapidly, and the Medical Department is being increased to meet its growing requirements. Vacancies are always advertised in THE LANCET as they occur.

Candidates must be single and should be under 30 years of age, and they must have held a resident post, preferably that of house surgeon, in a large general hospital. As a rule they are required to take out a course in Tropical Medicine before they leave England for the Sudan. The fees for this course are paid by the Sudan Government, and in addition an allowance £25 per month is made, under certain conditions, to each selected candidate who attends it.

Inquiries for further information should be made to Dr. V. S. Hodson, 24, Welbeck-street, London, W.1, or to the Deans of the Principal Medical Schools.

WOMEN'S MEDICAL SERVICE FOR INDIA.

AMONG careers open to medical women abroad the Women's Medical Service for India deserves honourable mention. The Service is open to fully qualified medical women of British or Indian nationality, and with the present amount of Government subsidy the number of medical officers is limited to 44. Medical women proceeding to India to join the Women's Medical Service receive a sufficient sum for a first-class passage to India. On landing they are posted to one of the larger women's hospitals to gain Indian experience and to learn the language. For a further period they are appointed to act temporarily for medical women on furlough. They are then definitely appointed to the charge of hospitals. Private practice is allowed, provided it does not interfere with official duties. The only exception is in administrative or educational posts, when an allowance in lieu of practice is given. The amount obtained from practice varies according to the station, but in most cases it forms a fair addition to the salary, varying from £150 to £1000 a year.

Rates of pay are as follows :—

Years of service.	Overseas allowance per mensem.	Salary per mensem.	English equivalent* per annum.
1 to 3	Rs.100	Rs.450	£440
4 to 6	,,	Rs.500	£480
7 to 9	,,	Rs.550	£520
10 to 12	,,	Rs.600	£560
13 to 15	Rs.150	Rs.650	£600

* At rupee value 1*s.* 4*d.*

Furnished quarters are provided, representing an additional Rs. 150 per mensem.

Excellent opportunities for surgery—especial gynæcological—are found in the Women's Medic Service. To those who are not keen surgeo opportunities are likely to open in the future connexion with maternity and child welfare.

The cost of living in India is much higher th formerly, but it should be possible for a medic woman (with house provided) to meet actual hous hold expenses for about Rs.300 per mensem, leavi the remainder of her salary for dress and perso expenses. To this must be added the necessa saving to meet additional expense for furlough a leave spent in the hills.

Leave on average pay is earned at the rate of 2/11t of the period spent on duty.

Study-leave is granted to the extent of 12 mont in the total service and will not be granted more th twice in the course of an officer's service. Duri study-leave an officer draws half average pay, with study allowance at the rate of 12*s.* a day duri the course of study. Officers of European domic are entitled to four free return first-class passages fr a port in India to a port outside India in their wh service. The first passage is not granted until af the expiry of four years' approved service, and the after passages may be granted at intervals of not l than four years. There is a Provident Fund to whi members of the service contribute 10 per ce of their pay. The service contributes another per cent., which accumulates at interest and is repa on retirement.

Admission to the service is made by selection India and England—preference being given to th with Indian experience. Vacancies are few. Can dates in the United Kingdom should apply to t Hon. Secretary, United Kingdom Branch of t Countess of Dufferin's Fund, care of Major-Gene Sir Leonard Rogers, India Office, Whitehall, Lond Candidates in India should apply to the Chief Medi Officer, Women's Medical Service, Countess Dufferin's Fund, Simla and Delhi.

SPECIAL DIPLOMAS

DIPLOMA IN PUBLIC HEALTH.

THE following epitomises the instruction given at various universities and centres of medical education to medical men desiring to obtain diplomas in sanitary science, public health, hygiene, or State medicine, as this discipline is variously called. Resolutions, designed with a view of ensuring "the possession of a distinctively high proficiency, scientific and practical, in all the branches of study which concern the public health," have been adopted at various times by the General Medical Council. The diploma is registrable by the Council whose rules on the curriculum become binding on the educational bodies concerned. The new regulations, which came into force in 1924, extend the period of study and postpone the granting of a diploma until at least two years from qualification.

London School of Hygiene and Tropical Medicine.

The course of study for the Diploma in Public Health will commence on Sept. 29th in the premises in Keppel-street (Gower-street), the gift of the Rockefeller Foundation, which has excellent laboratories and research rooms, a fine lecture theatre and classrooms, library, and museum. The course, which will extend over a period of 12 calendar months, is arranged in compliance with the requirements of the General Medical Council, and students taking the course will be able, should they so desire, to proceed to the new academic Diploma in Public Health of London University. The curriculum has been planned on very practical lines, and includes, in addition to work with Medical Officers of Health in two selected areas, a large number of visits to places of pub health interest. A series of 5 o'clock lectures will given by eminent authorities on special subjec and these lectures will be open to members of t medical profession as well as to students of the Scho The London County Council, the City of London, a various other bodies have placed their resources at t disposal of the School for teaching purposes.

English Conjoint Board.

The regulations are as follows: The Examinat consists of two Parts. Part I. will be held in t months of January, June, and October, and Part in the months of January, June, and October in ea year. Candidates may enter for Parts I. and separately or at the same time, but they must p Part I. before proceeding to Part II. The Examinat in each part will be written, oral, and practical. Part will include a practical examination in Infecti Diseases, Food Inspection, and Inspection of selec Premises. Candidates who fail to satisfy the Examin in either part may present themselves again at t next Examination on payment of the same fe Candidates intending to present themselves for eit part of the Examination must give 14 days' notice writing to the Secretary, at the Examination H Queen-square, London, W.C.1.

Candidates will be admissible to Examination Part I. on producing evidence :—

1. Of being in possession of a registrable qualification Medicine, Surgery, and Midwifery.

2. Of having attended during a period of not less t five months at an Institution recognised by the Examin Board in England, practical instruction in (*a*) Bacteriol and Parasitology (including Medical Entomology) especi

heir relation to diseases of man and to those diseases of lower animals which are transmissible to man, during hours, of which not less than 150 hours have been upied in practical laboratory work. (*b*) Chemistry and sics in relation to public health, during 90 hours, of ch not less than 70 hours have been occupied in practical ratory work. (*c*) Meteorology and Climatology in tion to public health, during not less than 10 hours.

andidates will be admitted to Part II. of the amination on producing evidence :—

. Of having been in possession of a registrable qualification in Medicine, Surgery, and Midwifery during not less a two years, of being registered by the General Medical ncil, and of having completed the curriculum for the loma extending over a period of 12 calendar months sequent to the attainment of a registrable qualification.

Of having attended, after obtaining the registrable lification, instruction during not less than 80 hours at Institution recognised by the Examining Board in land in the following subjects :—(*a*) The Principles of lic Health and Sanitation for not less than 30 hours ; Epidemiology and Vital Statistics for not less than ours ; (*c*) Sanitary Law and Administration (including lic Medical Services) during not less than 20 hours ; Sanitary Construction and Planning during not less than ours.

Of having attended for three months the clinical practof a hospital for infectious diseases recognised by the mining Board in England and of having therein received ruction in the methods of administration. The certificate t state that the candidate has attended on one or more s in each week of the three months, that each attendance of two hours' duration, with a total attendance of ours.

. Of having been engaged during a period of not less n six months in acquiring a practical knowledge of the ies, routine and special, of public health administration er the supervision of a Medical Officer of Health, and having received, from such officer or other competent dical Officer during not less than three hours on each of working days, practical instruction in those duties and those relating to : (*a*) Maternity and Child Welfare vice ; (*b*) Health Service for children of school age, Venereal Diseases Service ; (*d*) Tuberculosis Service ; Industrial Hygiene ; (*f*) Inspection and Control of Food ; uding meat and milk.

he above certificate (4) must be obtained from a dical Officer of Health who devotes his whole time public work, or from a Medical Officer of Health a Sanitary Area having a population of not less n 50,000, or in Ireland the Medical Superintendent icer of Health of a County or County Borough ring a population of not less than 50,000.

iversity of Oxford.

he examinations for Diplomas in Public Health re been suspended until further notice.

iversity of Cambridge.

wo examinations in so much of State medicine is comprised in the functions of medical officers ealth are held during the year. The examination ivided into two parts, and demands proficiency all the branches of study which bear upon the ies of medical officers of health. The examination both parts will be oral and practical, as well as writing. Candidates may present themselves either part separately ; but the result of the mination in the case of any candidate will not be lished until he has satisfied the examiners in both ts. Marks of distinction will be placed against the nes of candidates who have specially distinguished mselves in either (1) Part I. of the examination ; (2) Part II. of the examination. Candidates must ore admission to either part of the examination duce evidence of having satisfied the regulations licable to Part I. and Part II. The examination Part I. is in April and for Part II. in October.

For Part I. of the examination courses of lectures l laboratory instruction are given in the University Hygiene, Chemistry, &c., and on Bacteriology l Parasitology. For Part II. the Medical Officer Health for Cambridge gives courses on Practical nitary Administration and in the Administrative thods of the Infectious Diseases Hospital; and the dical Officer of Health to the Cambridgeshire County Council, on Sanitary Laws, School Hygiene, Epidemiology. There are also courses by special lecturers in Vital Statistics, Tuberculosis Service, Venereal Diseases Service, Industrial Hygiene, Maternity and Child Welfare. These courses are open to non-members of the University.

A special Diploma in Hygiene is granted to medical graduates whose qualifications are not registrable in England. The courses and examinations are the same as for the Diploma in Public Health (except that the candidates are not examined in English Sanitary Laws).

All applications for further information respecting examinations and the courses of study should be addressed to Mr. Purvis, Public Health Chemical Laboratory, Cambridge.

University of London.

Candidates for the M.D. Degree may offer State Medicine as a subject in which to graduate. The regulations may be obtained on application to the Academic Registrar, University of London, South Kensington.

University of Durham.

The Degree of Bachelor of Hygiene (B.Hy.) and the Diploma in Public Health (D.P.H.).—No candidate is admitted to the final examination for the Degree of B.Hy. unless he is a Bachelor of Medicine and Surgery, of not less than two years' standing, of a recognised University whose degrees are registrable on the books of the General Medical Council of the United Kingdom, and no candidate is admitted to the final examination for the D.P.H. unless he is a registered medical practitioner, of not less than two years' standing. The course of study for the B.Hy. and D.P.H. extends over a period of not less than 12 calendar months, subsequent to the attainment of a qualification registrable by the General Medical Council of the United Kingdom. Candidates for the B.Hy. must attend this course at the University of Durham ; candidates for the D.P.H. may attend it at the University of Durham, or at any medical school or institution which is recognised by the University. The examination for the diploma or degree is divided into two parts. A candidate must pass in all the subjects of Part I. before being admitted to examination for Part II. In Part I., and also in Part II., a candidate must pass in all the specified subjects at one time. The examination for Part I. is practical, written, and oral, and includes the following subjects : Bacteriology and Parasitology (including medical entomology) ; Chemistry and Physics, and Meteorology and Climatology, in relation to Public Health. Candidates are not admitted to examination for Part I. until after they have completed the prescribed courses of instruction in the subjects thereof. The examination for Part II. includes Hygiene and Sanitation (comprising sanitary construction), Epidemiology and Infectious Diseases ; Sanitary Law and Vital Statistics ; Public Health Administration. The examination is written and oral, and includes practical examinations in Infectious Diseases, Food Inspection, Inspection of Premises—Dwellings, Factories, Workshops, Schools, &c. Candidates are not admitted to examination for Part II. until after they have completed the prescribed courses of instruction in the subjects thereof. Doctor of Hygiene (D.Hy.) : Candidates must be Bachelors of Hygiene of the University of two years' standing, and are required to satisfy the examiners that they have conducted original research in the subject of Public Health.

University of Birmingham.

Under the rules and regulations of the General Medical Council the University grants a degree of B.Sc. in Public Health and also a Diploma in the same subject on the following conditions : Graduates in Medicine of this University may become candidates for the degree of Bachelor of Science in Public Health by conforming to all the requirements laid down for candidates for the Diploma in Public Health, except that after graduating in Medicine all courses

of study must be taken out in the University, and they must, in addition, have attended a three months' course of Geology in the University. A Thesis on the Ætiology and Prevention of a Disease of which the candidate has made a special study must be submitted on entry for B.Sc. Part II. The examinations will be held in the months of March and October, and will consist of two parts, each part being written, oral, and practical. No candidate will be allowed to pass Part II. until he has passed Part I. Candidates may enter for Parts I. and II. separately or at the same time. The fee for each part of the examination is £6 5*s*. Medical Officers of the Royal Navy who have attended the required course of study at the Naval Medical School, Greenwich, will be admitted to Part I. examinations for the Diploma in Public Health, whether they have previously been students at the Birmingham School or not; and the same applies to officers of the Royal Army Medical Corps who have studied at the Staff College. Medical Officers of the Navy and Army are admitted to Part II. Examination (D.P.H.) on complying with the requirements laid down for attendance upon Courses of Study. These Courses need not necessarily be attended in the University of Birmingham.

University of Liverpool.

The University grants a Degree in Hygiene (M.H.) and a Diploma (D.P.H.), and every facility is afforded for training in Sanitary Science and State Medicine. The curriculum for the Degree extends over a period of two years, the first of which is devoted to laboratory instruction and practical classes (including those for the Diploma); the second being devoted to advanced study and research. The courses may be taken at any time, and students are allowed to work daily in the laboratories.

University of Leeds.

The University grants a Diploma in Public Health, and every facility is afforded for training in Sanitary Science and State Medicine. The examination, which is held twice in each year—namely, in March and September—is in two parts, and is written, oral, and practical. Candidates must pass in Part I. before being admitted to Part II. Instruction in Entomology and Meteorology is given in the first term, and in Sanitary Chemistry and Bacteriology in the second and third terms. Practical work under arrangement with the Leeds City Council. Prospectus can be obtained from the Academic Sub-Dean of the Medical School.

University of Bristol.

Diploma in Public Health. Candidates must be at least 23 years of age, shall be fully registered medical practitioners of not less than two years' standing as such, and shall have passed the examination prescribed by regulations, which can be obtained from the Registrar upon application.

University of Wales.

Candidates for the Diploma in Public Health, the curriculum for which extends over a period of not less than twelve calendar months subsequent to the attainment of a registrable qualification, must produce evidence of having attended for not less than five months at the Welsh National School of Medicine practical instruction in Bacteriology and Parasitology, Chemistry and Physics, and Meteorology and Climatology in relation to Public Health. Candidates must also satisfy the examiners that they have received instruction approved by the University in the Principles of Public Health and Sanitation, Epidemiology and Vital Statistics, Sanitary Law and Administration, and Sanitary Construction and Planning. The candidate must also produce evidence that he has attended for three months on the clinical practice of a hospital for infectious diseases containing not less than 100 beds, and has received therein instruction in the methods of administration, and that he has for a period of not less than six months been engaged in acquiring a practical knowledge of the duties, routine and special, of a public health administration under the supervision of a medical officer of health. The examination for the diploma is divided into two parts, Part I. and Part II., each of which extends over not less than two days. A candidate must pass in all the subjects of Part I. before being admitted to Part II. of the examination. In Part I., and also in Part II., a candidate must pass in all the specified subjects at one time. Part I. of the examination is practical, written and oral, and comprises Bacteriology and Parasitology (including Medical Entomology); Chemistry and Physics, and Meteorology and Climatology in relation to Public Health. Candidates may not be admitted to Part I. of the examination until they have been certified as having pursued the prescribed courses of instruction in the subjects thereof. Part II. of the examination, which is written and oral, comprises: Hygiene and Sanitation (including Sanitary Construction); Epidemiology and Infectious Diseases; Sanitary Law and Vital Statistics; Public Health Administration. No candidate can be admitted to Part II. of the examination until after the lapse of not less than two years from the date of his obtaining a registrable qualification in Medicine, Surgery, and Midwifery, which qualification must be registered before admission to Part II. of the examination. An examination in each part will be held annually. The examination in Part I. will be held in June, that in Part II. in October. Full information may be obtained from the Registrar of the University, University Registry, Cathays Park, Cardiff. Entries for the examination in Part I. must be received by him not later than May 15th, and not later than Sept. 1st for the examination in Part II.

University of Edinburgh.

Candidates for the Diploma in Public Health must be graduates in medicine and surgery of the University, or hold corresponding degrees or registrable medical qualifications which must be registered before admission to examination. The course is divided into two parts for which examinations are held twice yearly, in March and July for Part I., and in October and March for Part II. In each part the candidate must pass in all the specified subjects at one examination. Candidates are not admitted to Part II. until they have passed Part I., nor until after the lapse of not less than two years from the date of obtaining a registrable medical qualification. The subjects of the examination are: Part I. (written, oral, and practical), Bacteriology; Medical Entomology and Parasitology; Chemistry, Physics, Meteorology, and Climatology. Part II. (written, oral, and practical), Hygiene, Sanitation, and Sanitary Construction; Epidemiology and Infectious Diseases; Sanitary Law and Vital Statistics; Public Health Administration. There is also included practical examinations in Infectious Diseases, Food Inspection, and Inspection of Premises. The course, which extends over a period of 12 calendar months, begins in October, and provision is made by the University for instruction in all the subjects. Detailed particulars may be obtained from the Dean of the Faculty of Medicine.

University of Aberdeen.

Every candidate for the Diploma in Public Health must be a graduate in medicine of the University of Aberdeen, or of any other University whose medical degrees are recognised as qualifying for registration by the General Medical Council of the United Kingdom. No candidate will be admitted to the Final Part of the Examination for the Diploma until after the lapse of not less than two years from the date of his obtaining a registrable qualification in Medicine, which qualification shall have been registered before such admission. The whole of the prescribed curriculum of study must be undertaken after the candidate has obtained a registrable qualification in medicine, and shall extend over not less than twelve calendar months. At least one academic term must be spent at the University of Aberdeen. Candidates shall produce evidence of having compl

ith the following requirements in respect of study
id training:—1. Practical instruction in the follow-
g subjects within a laboratory or laboratories
pproved by the University: (*a*) Bacteriology and
arasitology (including Medical Entomology), in
lation to diseases of man and diseases of lower
imals transmissible to man—at least 180 hours, of
hich not less than 150 shall be occupied in practical
boratory work; (*b*) Chemistry and Physics, in
lation to Public Health—at least 90 hours, of which
ot less than 70 shall be occupied in practical labora-
ry work; (*c*) Meteorology and Climatology, in
lation to Public Health—at least 10 hours; such
struction to extend over not less than five months
two academic terms. 2. A course or courses of
struction extending over not less than 80 hours
aling with: (*a*) The Principles of Public Health
id Sanitation—30 hours; (*b*) Epidemiology and
ital Statistics—20 hours; (*c*) Sanitary Law and
dministration (including Public Medical Services)—
) hours; (*d*) Sanitary Construction and Planning—
) hours; such course or courses to be given at an
stitution or by a teacher or teachers approved by
ie University. 3. Practical instruction, clinical and
lministrative, within a recognised hospital for
neral infectious diseases; such instruction to
tend over three months, and to include 30 daily
tendances of not less than two hours in each week.
Practical instruction and experience, during not
ss than six months (including attendance of at
ast three hours on each of sixty working days) in
ie duties, routine and special, of public health
lministration, under the supervision of a medical
ficer of health, who shall certify that the candi-
ite has received from this officer or other com-
tent medical officer, practical instruction in these
ities, and also in those relating to: (*a*) Maternity
id Child Welfare Service; (*b*) Health Service for
hildren of School Age; (*c*) Venereal Diseases
rvice; (*d*) Tuberculosis Service; (*e*) Industrial
ygiene; (*f*) Inspection and Control of Food, in-
uding meat and milk. The medical officers of
alth recognised for this purpose by the General
edical Council are: (*a*) a medical officer of health
ho devotes his whole time to public health work;
(*b*) the medical officer of health of a sanitary area
aving a population of not less than 50,000; or
) in Ireland, the medical superintendent officer of
alth of a county or county borough having a
opulation of not less than 50,000. The examination
r the diploma is divided into two parts, each of
hich extends over not less than three days.

niversity of Glasgow.

Degree of B.Sc. in Public Health.—Candidates must
e graduates in Medicine of a University of the
nited Kingdom, or of some other University
cognised for the purpose by the University Court.
andidates must produce evidence (1) that, after they
ave obtained a registrable Degree in Medicine, a
eriod of not less than two years has elapsed; (2)
iat, after they have obtained a registrable degree in
edicine, they have, during a period of not less than
l calendar months, pursued the course of work and
struction prescribed, and have satisfied the examiners
the prescribed examinations.
There are two examinations. Part I. includes
ie following subjects: (i) Bacteriology and Parasi-
ology (including Medical Entomology); (ii) Chem-
try and Physics in relation to Public Health;
ii) Meteorology and Climatology in relation to
ublic Health; (iv) Higher Chemistry in relation to
ublic Health; (v) Physics and Geology. A candi-
ate must pass in the subjects marked (i), (ii), and
ii) of Part I. at one examination. Part II.
cludes the following subjects: (vi) Hygiene and
anitation (including Sanitary construction); (vii)
pidemiology and Infectious Diseases; (viii) Sani-
ry Law and Vital Statistics; (ix) Public Health
dministration; (x) Applied Hygiene. The exami-
ation for Part II. includes practical examinations
Infectious Diseases; Food Inspection; Inspection of Premises, such as dwellings, factories, workshops, schools, and the like. The examination in Applied Hygiene may be on a selected subject professed by the candidate. A candidate must pass in the subjects marked (vi), (vii), (viii), and (ix) of Part II. at one examination. *Diploma in Public Health (D.P.H.).*—Candidates for this Diploma must be legally qualified medical practitioners who are matriculated students of the University. A period of not less than two years must elapse between the attainment by the candidate of a registrable medical qualification, and his admission to the final examination (Part II.) for the Diploma. The candidate must, during a period of not less than 12 calendar months, subsequent to his attainment of a registrable medical qualification, pursue the course of work and instruction prescribed, and pass the prescribed examinations. The examination, which is both written and oral, is divided into two parts, Part I. and Part II., each of which extends over not less than two days. No candidate is admitted to either part of the examination until he has completed the prescribed courses of instruction in the subjects of that part. No candidate is admitted to Part II. until he has passed in all the subjects of Part I., nor until after the lapse of not less than two years from the date of his obtaining a registrable medical qualification, nor unless he presents a certificate showing that his name and qualification have been duly registered in the Medical Register. Part I. includes: (i) Bacteriology and Parasitology (including Medical Entomology); (ii) Chemistry and Physics in relation to Public Health; (iii) Meteorology and Climatology in relation to Public Health. A candidate must pass in all the subjects at one examination. Part II. includes: (iv) Hygiene and Sanitation (including Sanitary Construction); (v) Epidemiology and Infectious Diseases; (vi) Sanitary Law and Vital Statistics; (vii) Public Health Administration. A candidate must pass in all the subjects at one examination. The examination for Part II. includes practical examinations in Infectious Diseases; Food Inspection; Inspection of Premises, such as dwellings, factories, workshops, schools, and the like.

University of St. Andrews.

The Diploma in Public Health is open to those who hold a registered medical qualification of the United Kingdom. The examination is in two parts. (1) (*a*) Bacteriology and Parasitology; (*b*) Chemistry and Physics; (*c*) Meteorology and Climatology. (2) Public Health and Sanitation, Epidemiology and Vital Statistics, Sanitary Law and Administration, and Sanitary Construction and Planning. Before admission to the first examination the candidate must have held his medical qualification for one year, and before admission to the second examination for two years. Graduates in Medicine of the University of St. Andrews may take part or all of the qualifying classes in any University of the United Kingdom, or in any Indian, Colonial, or Foreign University or medical school recognised by the University Court, but holders of other registered medical qualifications must spend at least eight out of the 12 months' curriculum in St. Andrews University. A complete course is given in the Conjoint Medical School, Dundee.

Scottish Conjoint Board.

All candidates for the Diploma in Public Health must have a qualification which has been registered under the Medical Acts. The examination is divided into two parts.

For Part I. the candidate must produce evidence of having received during a period of not less than five months at an institution recognised by the Board practical instruction in: (*a*) Bacteriology and Parasitology (including Medical Entomology), especially in their relation to diseases of man and to those diseases of the lower animals which are transmissible to man, during 180 hours, of which not less than 150 hours have been occupied in practical

laboratory work; (*b*) Chemistry and Physics in relation to Public Health during 90 hours, of which not less than 70 hours has been occupied in practical laboratory work; (*c*) Meteorology and Climatology in relation to Public Health during not less than 10 hours. For Part II. evidence must be given of having received instruction during not less than 80 hours in: (*a*) The Principles of Public Health and Sanitation for not less than 30 hours; (*b*) Epidemiology and Vital Statistics for not less than 20 hours; (*c*) Sanitary Law and Administration (including Public Medical Services) during not less than 20 hours; (*d*) Sanitary Construction and Planning during not less than 10 hours; of having attended for three months the clinical practice of a recognised hospital for infectious diseases; and of having been engaged during a period of not less than six months in acquiring a knowledge of Public Health administration in addition to practical instruction in the duties relating to: (*a*) Maternity and Child Welfare Service; (*b*) Health Service for Children of School Age; (*c*) Venereal Diseases Service; (*d*) Tuberculosis Service; (*e*) Industrial Hygiene; (*f*) Inspection and Control of Food, including meat and milk. The fee is 12 guineas for both examinations, or 6 guineas for either of them. A fee of 6 guineas is payable by rejected candidates for either examination. The examination is held twice yearly, in March in Glasgow, and October in Edinburgh. The published regulations provide detailed synopses of the subjects of examination. The Registrar for Edinburgh is Mr. David Thomson, 49, George-square, and for Glasgow, Mr. Walter Hurst, 242, St. Vincent-street.

University of Dublin (Trinity College).

The Diploma in Public Health is conferred, after examination, under the following conditions. The candidate must be a registered medical practitioner and have obtained a registrable qualification at least two years before the second part of the examination. The candidate must have completed, subsequently to obtaining a registrable qualification, five months' practical instruction in a chemical and bacteriological laboratory, or laboratories, approved by the University, must have received instruction in the following subjects: the principles of public health and sanitation, epidemiology and vital statistics, sanitary law and administration (including public medical services), sanitary construction and planning; must have studied, practically, outdoor sanitary work for six months under an approved officer of health, and must have attended for three months at a fever hospital where opportunities are afforded for the study of methods of administration. The De Renzy Centenary Prize, value about £15, is awarded to the candidate who obtains the highest marks at the June examination each year, provided sufficient merit is shown. A special prospectus may be obtained by application to the Registrar of the School of Physic, Trinity College, Dublin.

National University of Ireland.

At this University there is a Diploma in Public Health, a B.Sc. in Public Health, and a D.Sc. in Public Health.

University of Belfast.

A Diploma in Public Health is given by examination. Every candidate must produce evidence that, after obtaining a registrable qualification, he has during six months received practical instruction in an approved laboratory in which Chemistry, Bacteriology, and the Pathology of the diseases of animals transmissible to man are taught. After obtaining a registrable qualification every candidate must produce evidence that he has attended during three months the practice of a hospital for infectious diseases at which opportunities are afforded for the study of methods of administration. The examination must have extended over not less than four days, one of which shall have been devoted to practical work in a laboratory, and one to practical examination in, and reporting on, subjects which fall within the special outdoor duties of a medical officer of healt The first part of the examination will have referen to the general principles of Sanitary Science, and t second part to State Medicine and to the applicatio of Pathology and Sanitary Science. The examinati in both parts is held twice a year, in March and Jun

Irish Conjoint Board.

Every candidate for the Diploma in Public Heal must observe the following rules: 1. A period of n less than two years shall elapse between t attainment by a candidate of a registrable qualific tion in Medicine, Surgery, and Midwifery, and h admission to the Final Examination for a Diplon in Public Health. 2. The curriculum for a Diplon in Public Health shall extend over a period not less than 12 calendar months subsequent the attainment of a registrable qualificatio 3. Every candidate shall produce evidence having attended, during a period of not less th five months, at an institution approved by t Licensing Body granting the Diploma, practic instruction in—(*a*) Bacteriology and Parasitolo (including Medical Entomology), especially in th relation to diseases of man, and to those diseases the lower animals which are transmissible to ma (*b*) Chemistry and Physics in relation to Pub Health; (*c*) Meteorology and Climatology in relati to Public Health. At least 180 hours must be devot to Course (*a*), of which not less than 150 hours sh be occupied in practical Laboratory work. At lea 90 hours must be devoted to Course (*b*), of which n less than 70 hours shall be occupied in practic Laboratory work. At least 10 hours must be devot to Course (*c*). 4. Evidence of having received, duri not less than 80 hours, at an institution or fro teachers approved by the Licensing Body granti the Diploma, instruction in the following subject (*a*) The Principles of Public Health and Sanitatio (*b*) Epidemiology and Vital Statistics; (*c*) Sanita Law and Administration (including Public Medi Services); (*d*) Sanitary Construction and Plannir 5. Evidence that he has attended for three mont on the clinical practice of a recognised Hospital f Infectious Diseases. 6. Evidence that he has, during period of not less than six months, been engaged acquiring a practical knowledge of the duties, routi and special, of Public Health Administration und the supervision of a Medical Officer of Healt The examination for the Diploma is divided into t parts. The examination for Part I. includes Bacter logy and Parasitology (with Medical Entomology Chemistry and Physics, and Meteorology and Clim tology, in relation to Public Health. The examir tion for Part II. includes Hygiene and Sanitati (with Sanitary Construction); Epidemiology a Infectious Diseases; Sanitary Law and Vit Statistics; Public Health Administration. The exa ination, which is written and oral, includ practical examinations in Infectious Diseases; Fo Inspection; Inspection of Premises—dwellings, fa tories, workshops, and schools.

DIPLOMA IN TROPICAL MEDICINE.

Although a qualification in tropical medicine h not been made registrable by statute, a diploma regarded as indispensable for appointments in t Colonial Medical Service and similar positions abro Systematic instruction for these diplomas is given the Incorporated Liverpool School of Tropical Medici (founded in 1898) and at the London School Hygiene and Tropical Medicine, Keppel-street, Gow street, London, W.C.; while the Universities Cambridge, Edinburgh, and the English Conjoi Board grant the diploma.

London School of Hygiene and Tropical Medicine.

There are two courses of study in Tropical Medici and Hygiene in the year, each lasting 20 weel inclusive of examinations. The dates for t commencement of the next courses are Sept. 30

0, and Feb. 2nd, 1931. The course covers the k required for the D.T.M. & H. (England), and t of that required for the M.D. in Tropical Medicine the University of London.

iversity of Liverpool.

The University grants a Diploma in Tropical dicine. At the end of each full course an examina- is held by the University for its Diploma of pical Medicine (D.T.M.), which is open only to those o have been through the course of instruction of school. The subjects of examination are (*a*) asitology and Tropical Pathology. (*b*) Entomo- y. (*c*) Tropical Medicine, including Ætiology, nptoms, Diagnosis and Treatment of Tropical eases. The advanced course consists entirely Practical and Clinical Laboratory Work, given the Laboratory at the University. Applications uld be made to the Dean of the Medical Faculty, iversity of Liverpool.

The University also grants a diploma in Tropical giene (D.T.H.). The subjects of examination are Tropical Hygiene (including Sanitary Engineering, al Statistics and Epidemiology and Applied asitology and Entomology). (*b*) Practical Sanita- n. (*c*) Bacteriology. (*d*) Chemistry (including eorology and Climatology). Two University lowships of £100 a year each are open to students the school, amongst others. Accommodation research work is to be had at the University oratory. The Mary Kingsley Medal is awarded the school for distinguished work in connexion h Tropical Medicine.

iversity of Cambridge.

The examination for the Diploma in Tropical dicine and Hygiene is divided into two parts. t I. is held in Cambridge in April and Part II. uly in London. Candidates for Part I. are exam- d under the same regulations and in the same jects as candidates for the Diploma in Public alth, but any qualification in medicine or surgery gnised by the proper authority of any country side the British Dominions may be recognised. subjects for Part II. are Medicine, Surgery, and giene in their relation to Tropical Disease.

The examination will be partly in writing, partly al, and partly practical or clinical (the clinical t will be conducted at a hospital for tropical eases, at which cases will be submitted for diagnosis l comment). Every candidate who passes the mination to the satisfaction of the examiners will ive from the University a diploma (D.T.M. & H.) ifying to his knowledge and skill in tropical dicine and hygiene.

Further information respecting the courses of dy and examinations may be obtained from Mr. E. Purvis, Public Health Chemical Laboratory, nbridge.

iversity of Edinburgh.

Candidates for the Diploma in Tropical Medicine Hygiene must be graduates in medicine and gery of the University of Edinburgh or hold responding registrable degrees or qualifications of e other licensing body. The course of instruction, prising a primary and a second course, is given ing the autumn and spring terms, October to ch, and includes Tropical Hygiene, Bacteriology, omology and Parasitology, Diseases of Tropical nates (systematic and clinical), Tuberculosis, and ereal Diseases. The primary course alone is also en during the summer term, April to June. Pro- on is made in the University for instruction in all jects.

The examinations are written, oral and practical, are held at the end of the courses. Candidates required on the first occasion of presenting mselves for examination to appear for all the jects. Candidates who fail to pass the entire mination within a period of 12 months after first earance are required to reappear for all the subjects. The University is included in the list of Institutions whose courses of instruction in Tropical Medicine may be taken by officers on appointment to the Colonial Medical Services or during study-leave. Full particulars can be obtained from the Dean of the Faculty of Medicine.

English Conjoint Board.

The diploma of D.T.M. and H. Eng. is awarded on the results of an examination held twice yearly, in March and July. Candidates must possess a registrable qualification, and produce evidence of having attended (1) practical instruction in pathology, protozoology, helminthology, entomology, bacteriology, and hygiene in relation to tropical medicine in a recognised institution during not less than five months; (2) clinical practice of a recognised hospital for the same period. Conditions of study may be modified in the case of candidates of special experience. Further particulars from the Secretary, Examination Hall, Queen-square, London, W.C.1.

DIPLOMA IN PSYCHOLOGICAL MEDICINE.

The Universities of Cambridge, London, Durham, Leeds, Manchester, Edinburgh, Dublin, National University of Ireland, and the Conjoint Board of the R.C.P. Lond. and R.C.S.Eng. now grant diplomas in psychological medicine under conditions that are fairly comparable in the standard of the tests and in the duration of the courses; the details on these points can be obtained from the various examination bodies.

In London, courses of instruction for the Diploma in Psychological Medicine are given annually at the Maudsley Hospital, Denmark Hill, which has recently been definitely recognised as a school of the University of London. The course consists of two parts, commencing in January, and is adapted for the diploma of the Conjoint Board, the University of London, or the University of Cambridge. The parts may be taken separately; also during the year there are other short courses, lectures and demonstrations in psychological medicine.

Maudsley Hospital.

Appointments as clinical assistants are obtainable at the Maudsley Hospital. The holding of such appointments for varying periods satisfies the requirements of the different examining bodies in respect of practical study of mental disorders. The appointments and other facilities for clinical experience are open to qualified medical practitioners apart from the courses of instruction. Inquiries as to lectures should be addressed to the Director of the Central Pathological Laboratory, Maudsley Hospital, Denmark Hill, S.E.; and as to clinical facilities, to the Medical Superintendent at the same address.

Bethlem Royal Hospital.

A course of lectures and practical instruction for the Diploma in Psychological Medicine, granted by the various universities and the Conjoint Board, is held at Bethlem Royal Hospital, Monk's Orchard, Eden Park, Beckenham, twice annually, during the spring and autumn. The fee for the full course is 15 guineas. Part A or Part B, however, may be taken separately at a fee of 10 guineas per part. In addition to the above, clinical instruction in Psychological Medicine is given at Bethlem Royal Hospital every morning (except Wednesdays) at 11 A.M. The fee for students is 3 guineas for a period of three months' attendance and for post-graduates a fee of 5 guineas for a like period. A reduction is made to those who attend the Diploma Course. House physicians are appointed at Bethlem Royal Hospital for a term of six months, which may be extended. These appointments are made on May 1st and Nov. 1st in each year, and the vacancies are

advertised in the medical papers. Apartments, complete board, attendance, and laundry are provided and also a salary at the rate of £100 per annum. Clinical assistants are often appointed from time to time for periods of three months or longer. These are non-salaried and non-resident posts, but partial board is provided. The Physician-Superintendent, Bethlem Royal Hospital, Monk's Orchard, Eden Park, Beckenham, will supply further particulars.

University of Edinburgh.

Candidates for the Diploma in Psychiatry must be graduates in medicine and surgery of the University of Edinburgh or hold corresponding registrable degrees or qualifications of some other licensing body. Candidates are required subsequent to the date of graduation or obtaining a registrable qualification to have held (*a*) a resident appointment for one year in a hospital for mental disorders approved by the Faculty of Medicine, or alternatively (*b*) a six months' appointment as defined in (*a*) and six months' practical study of nervous diseases in a special or general hospital approved by the Faculty of Medicine. There are two examinations for the Diploma. Part I. comprises: 1. Anatomy of the Nervous System. 2. Physiology of the Nervous System. 3. Psychology and Experimental Psychology. Part II. comprises: 1. Neuropathology. 2. Clinical Psychiatry. 3. Clinical Neurology. 4. An additional subject selected by the candidate from a prescribed list. The examinations are held twice yearly in March and July. Candidates who have held an asylum appointment for a period of five years or more may be exempted from the course of study in one or more subjects of the curriculum. Full particulars can be obtained from the Dean of the Faculty of Medicine.

Dublin University.

A post-graduate diploma in Psychological Medicine is conferred upon registered medical practitioners who have held a resident medical appointment at a recognised institution for the treatment of Mental Diseases for 12 months, or who have held such an appointment for six months and have attended clinical instruction at an approved institution for six months. Candidates must also attend special courses of instruction and pass a special examination. Details can be obtained from the Registrar of the School of Physic, Trinity College, Dublin.

National University of Ireland.

This university confers a diploma in Psychological Medicine; application should be made to the Registrars of the Constituent Colleges, University College, Dublin University College, Cork, and University College, Galway, for all information.

DIPLOMA IN OPHTHALMIC MEDICINE.

Special diplomas in ophthalmic medicine and surgery are issued by two examining bodies.

University of Oxford.

The diploma in ophthalmology (D.O) is granted to registered medical practitioners after passing an examination, held annually in June, which is open to candidates who have pursued at Oxford a course of study in ophthalmology over a period of at least two months and who have attended a 12 months' recognised hospital course. Further information regarding these requirements may be obtained from the Dean of the School of Medicine.

English Conjoint Board.

The Conjoint Board grants the D.O.M.S. after an examination held in two parts, twice yearly in February and July. Part I. comprises anatomy and embryology of the visual apparatus, physiology of vision, and elementary optics. Part II. comprises optical defects, ophthalmic medicine and surgery and pathology with special reference to ophthalmolog The examination in each case is written, oral, a practical or clinical. Candidates may only enter Part II. on completion of a year of special study ophthalmology after obtaining a registrable diplor or a Degree in Medicine and Surgery of a Universi recognised by the Board.

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY.

University of Cambridge.

The D.M.R.E. is open only to those who ha held for at least one year a medical qualificati approved by the Committee. The new regulatio which came into operation in October, 1928, in sor respects materially alter the scope of the Diplon The course now occupies nine months, beginni in October. The first three months, which can spent either in Cambridge or in London, are occupi with lectures and practical work in Physics in prepa tion for the examination for Part I. in Januai and an introductory course in Radiology and Elect logy. The second three months must be spent London. The course includes lectures and clinic instruction in Radiology and Electrology, wi clinical practice in the radiological departme of a hospital approved for that purpose by t Committee. The examination for Part II. is he in April. During the final three months a candida must hold a clinical clerkship or similar appointme in a radiological department approved by the Co mittee, and must then present an exercise in t form of a critical report with notes upon six ca either in Radiology or in Electrology or in both the subjects, illustrating various methods of diagnos or treatment. Under certain circumstances previous experience, the third three months may excused, but the standard of the exercise or thesis expected to be considerably higher. A number large provincial hospitals have been approved by t Commitee to take clinical assistants for this part the course.

Further particulars as to courses and examinatio may be obtained from G. Stead, M.A., Cavendi Laboratory, Cambridge, Secretary for the Diplon or from Dr. A. E. Barclay, Department of Radiolog Medical School, Cambridge, or from Dr. Stanl Melville, British Institute of Radiology, 32, Welbec street, London, W. 1.

University of Liverpool.

Candidates before admission to the examinati for this diploma must possess a registrable qualificati approved by the University in medicine and surge and must have attended courses of instruction (*a*) physics (two terms), (*b*) (i.) radiology, and electrology during six months in the X ray a electrotherapeutic department of a hospital hospitals. An examination is held in March ea year, the subjects being (*a*) physics, (*b*) radiology a electrology. Examination in either part may taken separately. These courses commence duri the first week in October. Application should made to the Dean, Faculty of Medicine, the Universi of Liverpool.

University of Edinburgh.

Candidates for the Diploma in Radiology (D. Univ. Edin.) must be graduates in medicine a surgery of the University of Edinburgh or hc corresponding registrable degrees or qualification fr some other licensing body. Candidates are n admitted to the examination for the Diploma un after the lapse of not less than one year from obtaini a registrable qualification, which qualification mu be registered before admission to the Examinatio The course of study begins in October and extends ov a period of not less than three terms. The Examir tion, which is written, oral, and practical, is in t

arts: (*a*) Physics, and (*b*) Radiology. The Examination is held twice yearly—viz., July and October. Radiology can be taken as the special subject in the examination for Membership of the Royal College of Physicians of Edinburgh, which means that an Honours standard has to be attained. Full particulars may be obtained from the Dean of the Faculty of Medicine.

DIPLOMA IN LARYNGOLOGY AND OTOLOGY.

English Conjoint Board.

The Board grants the D.L.O. after an examination held in two parts, in June and December. Part I. comprises anatomy, embryology, and physiology of the ear, nose, pharynx, larynx, trachea and bronchi, and œsophagus. Part II. comprises the medicine, surgery, and pathology of the ear, nose, pharynx, larynx, trachea and bronchi, and œsophagus, and the recognition and use of special instruments and appliances. The examination in each case is written, oral, and practical or clinical. Candidates may only enter for Part II. on completion of one year of special study of the diseases of the ear, nose, pharynx, and larynx, after obtaining a registrable qualification, or a degree in medicine and surgery of a University recognised by the Board. The fee for admission to each part is 6 guineas.

DIPLOMA IN TUBERCULOUS DISEASES.

University of Wales.

The regulations governing the award of the Diploma of T.D.D. prescribe that every candidate must have obtained a registrable qualification in Medicine, Surgery, and Midwifery for at least two years before he can be admitted to the examination. He must have held, for not less than 12 months, a resident medical or surgical appointment on the staff of a Tuberculosis Hospital or Sanatorium, or at an Orthopædic Institution providing not less than one hundred beds for cases of surgical tuberculosis; or shall satisfy the Faculty of Medicine that he has pursued a special study of Tuberculosis equivalent to the above for a period of not less than 12 months. Every candidate must have pursued a course of instruction in the epidemiology, pathology, and bacteriology of tuberculosis extending over one term in the Welsh National School of Medicine, or an equivalent course of instruction extending over at least the same period in an institution approved by the University for this purpose. The examination is held annually in the first week of June. Notice of candidature, together with the entrance fee of £10 10*s*., and the necessary certificates, must be forwarded to the Registrar of the University, University Registry, Cathays Park, Cardiff, not later than May 1st.

The *Cecil Prosser Research Scholarship*, of the value of £250 for one year, is awarded triennially for research in Tuberculosis.

DIPLOMA IN BACTERIOLOGY.

University of London.

The University of London grants an Academic Diploma in Bacteriology, the Course being open to (*a*) Graduates in Medicine, Science and Pharmacy of this or another approved University, whose previous training has, in the opinion of the University, fitted them to profit by the Course; and (*b*) registered medical practitioners and other students who, though not graduates, have obtained a qualification and undergone a previous training which, in the opinion of the University, has fitted them to profit by the Course.

A Course necessary to fufil the regulations of this Diploma has been planned by the London School of Hygiene and Tropical Medicine, Keppel-street, London, W.C., and full particulars with regard to the Diploma may be obtained from the Academic Registrar, University of London, South Kensington, S.W.

DENTAL SURGERY

TEACHING INSTITUTIONS IN DENTISTRY.

REGISTRATION on the Medical Register entitles a practitioner to practise as a dentist, although he cannot register as such without degree or licence in dentistry; but few dental appointments at general or special hospitals or dispensaries are available save to those with a special diploma, and, until registered on the Dentist Register, no dental work under the Additional Benefit Scheme of the National Health Insurance Act can be undertaken.

The Examining Bodies in Dentistry which grant degrees and diplomas in the subject are as follows: Royal College of Surgeons of England, Royal College of Surgeons, Edinburgh, Royal Faculty of Physicians and Surgeons of Glasgow, Royal College of Surgeons in Ireland, and the following Universities: Birmingham, Bristol, Durham, Leeds, Liverpool, London, Manchester, Sheffield, St. Andrews, Dublin (Trinity College), Queen's University of Belfast, and the National University of Ireland. The student should apply to the secretaries of the various Conjoint Boards or to the Deans of the medical faculties or medical schools for a syllabus.

TEACHING INSTITUTIONS IN LONDON.

Royal Dental Hospital.

The Royal Dental Hospital of London, School of Dental Surgery, Leicester-square, is a school of the University of London. Women are admitted as students and are eligible for all hospital appointments and school prizes. The school provides the special dental education required by the University of London for the B.D.S. Degree and the Royal College of Surgeons for the Licence in Dental Surgery. The general part of the curriculum may be taken at any general hospital. The hospital is open from 9 A.M. to 5 P.M., there being one staff for the morning and another for the afternoon of each day. Pupils are received for the training in dental mechanics recognised by the curriculum. The instructors at the commencement of each session give a course of lectures on Operative Dental Surgery. The five house surgeoncies are held for four months each and are open to all qualified students. The lecturers, in addition to their lectures, give special demonstrations on the Microscopy of Dental Anatomy and Dental Surgery. The lecturer on Dental Mechanics also gives practical demonstrations in the laboratory. There is an Entrance Scholarship in Chemistry and Physics of the value of £25. One Entrance Scholarship in Dental Mechanics and Metallurgy, value £25. For full information as to scholarships and prizes, and other matters connected with the course, application should be made to the Dean.

University College Hospital Dental School.

This Hospital and School, situated at the corner of Great Portland and Devonshire-streets, W., has recently been thoroughly reorganised, and is now fully equipped with all the most modern appliances. Students are entered as students of University College Hospital, and, as such, attend the classes of Anatomy

and Physiology in University College, which is a few minutes' walk from the Dental Department in Great Portland-street, hitherto known as the *National Dental Hospital*, the first Dental School to admit Women Students. Practical courses to comply with the R.C.S. curriculum are held. Clinical Lectures and Demonstrations are given, and each student on entering passes through a preliminary course under a demonstrator. A prospectus containing full information as to lectures, fees, and prizes may be had on application to the Sub-Dean for Dental Students, who attends at University College Hospital Medical School, University-street, W.C.1, on Wednesday mornings from 9.30 to 10.30, and at other times by appointment.

Guy's Hospital Dental School.

The work of the Dental Department begins daily at 9 A.M. both in the extraction rooms and in the conservation room. The Extraction Rooms: There is ample accommodation for both general and local anæsthetic extractions, together with waiting- and retiring-rooms. Patients are admitted between 8.45 and 9.30 A.M., and are seen by the dental surgeon for the day, the staff demonstrators, the dental house surgeons, and the dressers. The Conservation Room is open from 9 A.M. till 5 P.M. It affords accommodation for about 100 dental chairs, with the necessary equipment of the most modern type for the use of the Dressers, who, under the supervision of the Staff, perform the various operations of Dental Surgery. There is a separate room for denture patients affording accommodation for 15 chairs and a separate department for children with accommodation for 20 chairs. The Members of the staff attend every morning and afternoon to give demonstrations and otherwise assist students in their work in the Conservation Room and Prosthetic Laboratory. The Probationers' Laboratory is supervised by three of the staff demonstrators, and instruction is given in operative dentistry on a "mannikin" to students during their first three months of clinical study. Students in Dental Prosthetics are received, and a graded, systematic, and full course of instruction, extending over two years, is carried out under the supervision of the Director of the Prosthetic Laboratory, assisted by three demonstrators, a house surgeon, and seven mechanics.

Dental students have the opportunity of attending at this hospital the whole course of instruction required by the examining board for the B.D.S. Lond. or L.D.S. Eng.—viz., the complete course in dental prosthetics, the special lectures and practice of the Dental Department, and the general lectures and practice of the Medical School. Students who enter for a medical as well as a dental course are allowed to pursue their study of Dentistry during any period of their medical course most convenient to themselves without further charge.

Twelve house surgeons, 20 assistant house surgeons, and four student demonstrators of Dental Histology are appointed annually. The following appointments are held by students: Full surgeon's dresser, assistant surgeon's dresser, dresser in the children's department, casualty dresser, clerk to the anæsthetist, dresser in the gas extraction and local anæsthetic extraction rooms, and probationary dresser. For particulars as to scholarships and prizes, as well as all information, application should be made to the Dean of the Medical School, Guy's Hospital, London Bridge, S.E. 1.

King's College Hospital.

The Dental School is part of the Medical School of King's College Hospital, and was opened in November, 1923. The Dental Out-Patient Department of the Hospital is used for the performance of dental extractions. A large Conservation Room with provision for 40 dental chairs has been equipped. Smaller rooms are used for clinical teaching and administrative requirements, and a specially equipped laboratory for training in the art of dental mechanics. An X ray apparatus has been installed for special use in dental skiagraphy. A museum containing a lar number of specimens illustrating oral, buccal, dent and other diseases is available for teaching purpos The library, lecture theatre, lecture rooms, comm rooms, and the refreshment room are all availab for the use of students. Courses of study, includi practical work, are provided for the degree of Bachel of Dental Surgery of the University of London, a for the Diploma in Dental Surgery of the Roy College of Surgeons of England. Special arrangemen are made for those students who wish to take medical degree or qualification in addition to a degr or diploma in Dental Surgery.

The following salaried appointments are open qualified members of the School: Registrar, Reside House Surgeon, Non-Resident House Surgeon, a Tutors in Dental Mechanics, Orthodontics, a Dental Materia Medica.

Full particulars of the Dental School may obtained on application to the Dean, or to t Secretary of the Medical School, King's Colle Hospital, Denmark Hill, London, S.E. 5.

London Hospital.

This school is a part of the London Hospital a Medical College, and is fully equipped on the mo modern lines and with the latest appliances. provides a complete curriculum in all subjects f the B.D.S. Degree and for the L.D.S. Diploma, a is admirably adapted for the purpose of teachin The Conservation Room is well lighted a ventilated and fitted with pump chairs of t latest pattern; the fountain spittoons at many the chairs have been specially designed. Ea spittoon has attached to it a saliva ejector, hot a cold water, compressed air, gas and electric curre also a swing bracket to carry the students' cabine Electric sterilisers are supplied in each departme and motor engines where required. The Scho possesses, in addition to the Theatres, Laboratorie and Museums in the College, a special Museum Dental Anatomy and Surgery, Operative Dentistr Prosthetic and Extraction Rooms, and Laboratori for Practical Metallurgy and Prosthesis. A systemat course of instruction is arranged for pupils. The up-t date Laboratory contains every modern apparat and is in charge of a skilled curator and his assistant Entrance Scholarship: Francis Farmer Scholarsh in Science, value £25; no age limit. Subject Chemistry and Physics. Prizes: The Harold Fi Prize in Operative Dental Surgery, value £8 8s the "London" Prize in Dental Prosthesis, val £5 5s. Prizes are also offered for competition at t end of each of the courses of lectures in the curriculu Connected with the Medical College and Dental Scho are a Library, Athenæum, Clubs' Union, Dining H with moderate tariff, Students' Hostel, and an Athlet Ground. For full particulars as to Scholarships a Prizes, fees and course of study advised, apply to t Dean of the Medical School.

Royal Free Hospital: London School of Medici for Women.

Full courses are arranged for women students f the study of dentistry and in preparation for t B.D.S. Degree of the University of London and t Licence in Dental Surgery of the Royal College Surgeons of England, at the London (Royal Fr Hospital) School of Medicine for Women. T Eastman Dental Clinic will, when completed, provi a Dental School for women students; in the meantin the course for dental students is arranged in co junction with the Royal Dental Hospital.

TEACHING INSTITUTIONS OUTSIDE LONDON.

Birmingham Dental Hospital.

Dean: Cyril Howkins, C.B.E., D.S.O., M.R.C.S L.D.S. The Dental Hospital, Great Charles-stree has accommodation for 100 students. The equi ment is in accordance with the most modern requir ments for the efficient teaching and practice of Dent Surgery, including Radiology and Ultra-Violet Ra Therapy and a new department for Practical Patholo

d Bacteriology. The operations performed nually average 35,000, including gold and other tings, crowns, bridges, porcelain inlays, and injections c block and infiltration anæsthesia. The orthontic department is one of the foremost in the untry. The Prosthetic and Mechanical Departent is large and well lighted and under a highly illed instructor who is always present. Applicaon for information as to fees and scholarships must sent to the Dean of the Medical Faculty, Birmingm University, or the Dean of the Dental Hospital, rmingham.

eds University School of Dentistry.

The School of Dentistry is adequately equipped to ovide for the complete training of the dental student. forms a part of the Leeds School of Medicine whilst e instruction in clinical and mechanical dentistry is rried out in the Dental Hospital. The School is w in occupation of a spacious new building pecially designed to the requirements of modern ntal teaching. The School is also the dental partment of the General Infirmary, and its close sociation with the work of that institution ensures adequate supply of clinical material, and enables fuller insight into the position dental surgery lds in relation to general medicine and surgery, pecially with regard to the major diseases and juries of the head and neck. The courses of study e mainly designed to meet the requirements of the Ch.D. and L.D.S. Leeds, but every opportunity is orded to students preparing for the degrees or plomas of other licensing bodies. Full-time demonrators give the instruction in clinical dental surgery, osthetic dentistry, and mechanics, which is carried t under the supervision and direction of members of e Honorary Staff, two of whom are in attendance ch day. Special facilities are provided for instruction Orthodontia, Dental Radiography, Local and neral Anæsthetics. Prizes are offered for competion to pupils and students in their respective years study. Communications should be addressed to e Warden, School of Dentistry, Leeds, from whom prospectus may be obtained.

ntal Hospital of Manchester.

This hospital is in association for teaching purposes th the University of Manchester and the Royal firmary, and is in the centre of a very large popula-on. Courses of study are provided to met the quirements of the various examining bodies, cluding those of the University of Manchester for e qualifications L.D.S. and B.D.S., and the L.D.S. the Royal College of Surgeons of England. Clinical struction is given in Dental Prosthetics, Operative ntistry, Diagnosis and Extraction, Orthodontics, ental Surgery, Radiography, and Anæsthetics by ecially appointed Clinical Teachers.

All the courses of instruction are open to women udents. Copies of the Prospectus will be forwarded application to Mr. J. Hilditch Mathews, Dean.

ewcastle-upon-Tyne Dental Hospital and School.

This hospital is centrally situated (within 5 minutes the various colleges, infirmary, and railway station); e rooms are well lighted and thoroughly equipped r carrying on the work. Dental surgeons and an æsthetist attend each morning. A tutorial dental rgeon is also in attendance. Medals and Certiates of Merit are granted to students showing rtain standards of proficiency in the various classes the Dental School. The prospectus of the Dental ospital and School, containing full information, ay be obtained from Mr. James Coltman, 13, llison-place, Newcastle-upon-Tyne, Dean.

evon and Exeter Dental Hospital.

The hospital at 24, Southernhay West, Exeter, is en on Mondays, Tuesdays, Wednesdays, Thursdays, ridays, and Saturdays, and patients are admitted tween the hours of 9.30 and 11 A.M. Students tend the practice of the hospital under the control the medical officers.

SCOTTISH TEACHING INSTITUTIONS.

Edinburgh Dental Hospital and School.

The Edinburgh Dental Hospital and School is located in spacious and well-equipped buildings at 30, 31, and 32, Chambers-street, and offers special advantages to dental students. A large and important extension of the existing buildings has now been opened. The General Courses required for the Dental Diploma may be taken in the Medical School of the Royal Colleges of Physicians and Surgeons or in the University schools. The general hospital attendance and clinical instruction are taken at the Royal Infirmary. The University, Medical Schools, and Royal Infirmary are within three minutes' walk of the Dental Hospital. The special courses are taken in the hospital. The Dental Hospital practice, extending over two years, affords a student ample opportunity for a full acquaintance with every branch of dentistry. The hospital admits a limited number of indentured pupils. They receive their instruction in Mechanical Dentistry concurrently with the general and special courses. A premium of 60 guineas is payable with each such pupil. The practice and lectures of the hospital are recognised by, and qualify for, all the Licensing Boards. Those students who desire to take a Medical and Surgical Diploma in addition to the L.D.S. have in this school admirable facilities for so doing. The triple qualification of the Royal College of Physicians and Surgeons of Edinburgh and the Royal Faculty of Physicians and Surgeons of Glasgow is recommended. The Higher Dental Diploma (H.D.D.) of the Royal College of Surgeons affords an opportunity of obtaining a higher qualification subsequent to registration. The Prospectus, with full information, may be obtained by application to the Dean or the Assistant Secretary.

Incorporated Glasgow Dental Hospital.

This hospital is located at 158, Renfrew-street, and 15, Dalhousie-street, Glasgow. The school is open to Men and Women Students, and Lectures are given on Dental Surgery, Operative Dental Surgery, Orthodontia, Dental Anatomy and Physiology, Dental Histology, Dental Mechanics, Crown and Bridge work, Dental Metallurgy, Dental Bacteriology, Radiology, Anæsthetics, and Dental Materia Medica. Lectures on general subjects required for Dentistry may be taken at the University or at one of the extramural schools where special provision is made for Dental Students. A new mechanical laboratory with bench accommodation for 60 pupils and fully equipped with the most modern appliances for teaching practical dental mechanics has recently been added. Full information may be had on application to the Dean.

Glasgow Royal Infirmary.

Dental Department: The following course in the curriculum can be taken at St. Mungo's College: Anatomy, six months; Practical Anatomy, nine months; Physiology, six months; Chemistry, six months; Practical Chemistry, three months; Surgery, six months; Medicine, six months; Materia Medica, three months; Dental Surgery, six months, and attendance for two years on the dental department of the hospital. Clinical Medicine (three months) and Clinical Surgery (six months) are taken at the Royal Infirmary.

IRELAND.

Dental Hospital of Ireland.

All Dental Students who have passed their Second Dental Examination in the Royal College of Surgeons in Ireland (or an equivalent examination or examinations) are admissible to the Clinical Instruction of the Hospital. In addition to Clinical Instruction and Special Demonstrations, courses of lectures are given at the hospital on Dental Surgery and Pathology, Mechanical Dentistry, the Administration of Anæsthetics, Orthodontia, Dental Anatomy, and Dental Materia Medica, and instruction in Anæsthetics. The course in practical Dental Mechanics can be taken in the Hospital Laboratory. Further particulars can be obtained from the Dean, at Lincoln-place, Dublin.

AN ADDRESS

MEDICINE IN CANADA.*

By W. Harvey Smith, M.D., C.M. McGill,
PROFESSOR OF OPHTHALMOLOGY AT THE MANITOBA MEDICAL COLLEGE AND OPHTHALMOLOGIST TO THE WINNIPEG GENERAL HOSPITAL.

[After welcoming visitors from the Mother Country and expressing warm appreciation of the proposal to provide in London a great post-graduate centre for the teaching and practice of medicine, Prof. Harvey Smith continued :—]

At no period in our history has medicine stood higher in public esteem and confidence than to-day, and never has our profession enjoyed a greater measure of goodwill and public support than at the present time. Admittedly, however, certain phases of practice are open to criticism, and the Æsculapian guild is confronted with many problems pressing for solution. These relate mainly to costs, unavailability of medical aid, and lack of qualification.

State Medicine Impending in the West.

The ground-swell of dissatisfaction is felt especially in the west. In British Columbia, for example, the medical profession frankly admits that State medicine is impending, and plans for dealing with the situation, when it arises, on a basis that will be satisfactory both to the patient and the public. The trend towards State medicine at the coast is indicated by the report of the Royal Commission on State Health Insurance and Maternity Benefits—whose membership of five includes two physicians—recently submitted to the legislature, setting forth the results of an exhaustive study of health insurance which, while not complete, has progressed sufficiently to warrant the following conclusions :—

> Our investigations so far convince us that there is justification, and a general demand for the introduction in British Columbia, of an economically sound and equitable public health insurance plan, in the interests of the majority of provincial workers, of provincial industries, and of the State, in the more effective safeguarding and preservation of communal health, the more rational distribution of sickness costs, and the scientific reduction of such charges to the Government, to employers, and to individual citizens.

A TRAVELLING CLINIC.

In Alberta the tendency of the times is shown by a novel departure from accepted precedent, which has been sanctioned and established by the Government, and in the main approved by the medical profession. It has taken the form of a travelling clinic. The fear, so widely expressed by many physicians, that such a system will lead to State medicine is combated by the director of the clinic, who maintains that it will have the reverse effect, and that, by reaching the children in the rural communities, the principle of periodic health examinations will be carried to the parents. "Undoubtedly," he says, "the actual examinations and treatments given in the past have been of great benefit to these people, who cannot arrange to have examinations done and operations performed, if the service is not taken to them." While differences of opinion may exist as to the value of this travelling clinic as a manifestation of public policy in the domain of medicine, it has great significance.

In Saskatchewan certain developments of a ver radical character have taken place under Governmer auspices, and are being studied with interest by a who are concerned with medical practice an economics. These include the establishment of unio hospitals under the control of adjoining municipaliti which are supported through taxation and provid service at an extremely low rate, the employment physicians by the municipality on a salaried basi the provision of free nursing care for stated period and the assumption of financial responsibility by th province for the treatment of all tuberculous person

Cost of Medical Care.

Innumerable other examples of the prevailin trend in Canada could be cited from the Provinc of Quebec westward to the Pacific. In this connexio I may say that both the Canadian Medical Associatio and the Department of Pensions and Nation Health at Ottawa are making a study of medical ca and its cost, with a view to submitting constructiv recommendations at a later date. The monument task undertaken by our friends in the United State of embarking upon a five-year programme of invest gation into the cost of medical care is further eviden of the increasing importance of attempting to de constructively with this problem.

When under legislative authority a licence practise is granted, it simply indicates that th individual to whom it is issued has, at least, th minimum qualifications of a general practitioner. does not certify, however, that he possesses speci knowledge in any of the many divisions of medicin He may be a man of the highest character and ideal willing to place the welfare of his patient first, and avoid operations and procedures which he has neith the capacity nor the experience to perform. This true of the majority of practitioners. On the oth hand, he may be of a type, not unknown, th pretends to knowledge not possessed and qualificatio non-existent.

QUALIFICATION OF SPECIALISTS.

I need not emphasise the value to the communit of medical skill as a factor in shortening periods disability and reducing medical costs, but I wou like to stress the urgent need of securing, in Canad at least, such amendments to the different provinci medical Acts as would enable the governing bodi of our profession to pass upon the qualifications men purporting to be specialists. The Governmer has upon its statute books laws relating to th standardisation of weights and measures and ensure the purity and quality of products offered f sale. Surely it is more important that the medic skill available for the use of humanity should b approximately as represented.

Of recent legislation in Canada dealing with medic practice, that which stands out pre-eminently in i claim to attention is the statutory regulation specialism in the Province of Alberta, which is th most advanced legal enactment of its kind in th country. It provides that no practitioner can ho himself out to the public to be a specialist in ar recognised field of special practice unless he h received from the Senate of the University of th province a certificate that he has complied with certa specific requirements as to study and experienc Under this arrangement, bona fide specialists and th

* Abstract of the Presidential Address delivered at Winnipeg on August 26th, at the opening of the ninety-eighth annual meeting of the British Medical Association.

ublic of Alberta are being protected against unin-ructed, unskilled, and unqualified persons announc-ig themselves as specialists. The Alberta legislation unquestionably in the direction of a higher standard f education and competency in specialised and ideed in general practice as well. I feel justified in aying that it will be but a matter of time until the ther provinces follow the excellent lead thus given.

PROVISION OF SKILLED NURSING.

The nurse, as a major factor in the increasing cost f medical care, occupies an important position, and riticism of her and of the organisations which are sponsible for the educational and economic policies nder which she labours is free and insistent. It ay be that the nursing profession has failed to rovide semi-skilled, as well as skilled, service, and to evelop organisations and policies to meet every ype of technical and economic nursing requirement. ut careful surveys covering a wide field show that he professional nurse may justly voice a claim for ore consideration than she has received. She is mployed less than 60 per cent. of her time, earns r less than a skilled workman, and quite justly is issatisfied with her present status and her future rospects. Is there not some plan which could be dopted under which she may be freed from economic nxiety, and may satisfy the requirements of the ublic and the medical profession in the matter of ost and skill? I believe there is. We have in anada a national organisation (established under oyal charter) known as the Victorian Order of Nurses, hich was founded in 1897, at the time of Queen ictoria's Jubilee, by the Countess of Aberdeen.

This Order is represented in practically all the rger centres of population, and has established and aintains a visiting nursing service. It engages and irects the activities of its staffs of nurses, in the are of the sick, the demonstration of nursing methods, nd the prevention of disease, and offers at a reason-ble price a supervised service, on an hourly or daily asis, of every type, from that supplied by the highly rained registered nurse to the humble ministrations f the home helper. The members of its staff are arefully selected, and must submit to a period of hree months' probation. They are continuously mployed, and are allotted duties upon a basis of pecial aptitude and fitness. The national scope nd character of the organisation, the type and apacity of those who direct its activities, its wide eographical distribution and uniform policy and ethods, and its very close association with the edical profession of Canada make it fitting that his body should undertake to solve, in part at least, he problem of nursing cost and service. This would nvolve some realignment of its policies and prin-iples of management, and recognition on the part f the Order and of the medical profession of Canada f the possibility of securing all necessary nursing ervices at a minimum cost, that might result from he extension of the activities of the Order to meet he requirements of rural and urban nursing.

FINANCIAL TRAGEDY OF SICKNESS.

The fundamental considerations involved in medical ervice are cost and purchasing power. The particular ifficulty that confronts patients is that sickness or ccident are unforeseen, unanticipated, and usually nprovided for. Consequently, when the scourge of lness come to the home, the patient is seldom pre-ared to meet the financial obligations involved. Vhen it is realised that the annual incomes of 0 per cent. of the families in the United States (and this doubtless applies to Canada) is below $2000 a year, one can understand why the problem of sickness so often assumes the proportions of a financial tragedy.

It has been computed that 30 per cent. of patients are attended without charge by the medical profession, while a further 20 per cent. are treated at reduced rates. Hitherto the practitioner has cheerfully borne his burden, but the increasing cost of medical education and the greater demands that the practice of medicine makes to-day upon his time and energy, is causing restlessness and dissatisfaction that is freely voiced. The taxpayer not unnaturally views with complacency the operation of a system that relieves him of a vast financial responsibility, but it is becoming increasingly apparent that a readjustment of the economic basis upon which the members of the medical profession offer their services to the public should be effected, under which the principles will be exemplified that the labourer is worthy of his hire.

STATUS OF HOSPITAL MEDICAL STAFF.

The insistence by Dr. William Gerry Morgan, the distinguished President of the American Medical Association, in a recently delivered address, that the services of the profession of medicine to hospitals must be regarded as the contribution of the medical staffs as individuals, and that these services cannot become in any sense the property of the institution, will arouse a note of commendation in the minds of many physicians who, I believe, regard with disapproval and concern the increasing and inordinate demands of hospital directorates and officials for free medical aid.

While every effort should be made to lower medical costs by sound organisation, voluntary coöperation between physicians, the avoidance of unnecessary expensive methods of diagnosis, the provision of moderately priced accommodation, the availability of composite fees, and the insistence that physicians shall be adequately qualified, it seems inevitable that at the rate scientific medicine is progressing, the care of the sick in the future will cost more than it has done in the past, and we cannot expect that the purchasing power of the average family will be greatly increased.

Voluntary Health Insurance the Only Solution.

How, then, may the problem be solved of placing competent medical skill within reach of all our citizens, on a basis that will ensure them every care, be just to the members of our profession, and satisfy the legitimate demands of the nurse and the hospital? In my judgment, there is only one possible solution—voluntary health insurance, instituted, organised and controlled by the medical profession, and widely applied. The alternative is some form of State medicine, which implies an admixture of politics, the selection of officials and practitioners upon a basis of influence rather than of competence, the building up of a bureaucratic institution, insensitive to advanced public opinion, and subject to influence of an undesirable character. In the words of our honoured guest, Lord Dawson of Penn, "medicine must be unfettered; knowledge and the restless spirit which prompts its progress need a freedom and flexibility which cannot be found within the ringed fence of administrative departments"—while Dr. William Mayo says: "for the State to take over the care of ordinary illness would introduce civil service mediocrity, more drugs, more routine, and less scientific attention to the patient." The field of public health must and should be the interest of Government, but private practice must remain in

the hands of the individual physician if the public is to receive the highest and best type of medical care.

To the medical men of the Dominion, confronted with a demand for medical service at a lower cost, the great insurance system, established under the British National Health Insurance Act of 1911, has always had a special interest, and has been studied with the hope that it might afford a working basis upon which to establish a system of health insurance in Canada, should such be found desirable. While this system may not be free from imperfections, its success as a measure applicable to 16,000,000 people is attested by evidence of unimpeachable authority.

The recent proposal of the Council of the British Medical Association to establish a general medical service for the nation is of such a far-reaching and significant character that it is certain to have profound influence upon economic thought in the domain of medicine throughout the Empire. It is too early, and in Canada we are too remotely situated and too unfamiliar with the needs of British medicine, to attempt even an appraisal of its value and applicability to Old Country traditions.

THE LAW OF AVERAGE.

To the student of statistics it is apparent that the medical hazards and contingencies to which mankind is subject operate with unfailing regularity under the law of average, and can best be protected against by insurance—thus spreading the cost over a large number of people and reducing individual liability to a figure the average man can meet. In this connexion may I quote the views of Dr. Lee K. Frankel, of the Metropolitan Life Insurance Company, an outstanding authority on life insurance and related problems. He says:—

> "To-day we know that fire is a hazard, we know that accident is a hazard, and we provide against these hazards under the modern method of distributing the burden of the risk. Fundamentally this is the insurance principle. Knowing this have we not found the way out? Realising that sickness is a hazard of life, can we not apply the same principle to meet its cost as we have to the hazard of death, of accident, of fire, and to the other contingencies of life? The cost of sickness must be provided for in advance of sickness, and be distributed so that it bears equally upon all."

The conclusion therefore seems inevitable that for the large majority of our people health insurance, preferably of the voluntary type, affords a sound basis upon which to supply medical aid and skill.

Closer Relationship with the Mother Country.

At a period when every effort is being made to bring about closer Empire relationships in trade and sentiment, one cannot but feel that the harassing restrictions of licensure existing in British countries at the present time should be modified in favour of a system of intra-Empire licensure applicable to British practitioners of adequate antecedents, good education, and approved character. The situation, however, is one of extreme complexity, and hitherto it has not been possible to arrange an understanding that, so far as the Mother Country and Canada are concerned, might bring about a consummation devoutly to be wished. The reasons for this failure are partly economic and partly legal, but are mainly due to the apparent impossibility of devising a formula acceptable to all concerned. It is to be hoped that means may be found whereby conflicting views may be reconciled, and an understanding arrived at, under which reciprocal rights to practise may be granted upon a mutually satisfactory basis.

Abler lips than mine have paid tribute to th debt of Canada to British medical schools and teacher and to the system of medical instruction that prevai in the Old Country, and constituted the education foundation upon which the McGill and Toront Medical Schools were established. McGill wa organised by Scotsmen, and from its inception ha followed Edinburgh methods. In Toronto an Kingston the traditions of the London rather than th Edinburgh school have prevailed. The Manitob Medical College was founded by graduates of McGi and Toronto.

Manitoba Medical College.

The story of this College, which was begun in th pioneer period, when Winnipeg was still an unrul frontier town, fairly deserves an honourable pla in the history of medical education. In 1883 1 Winnipeg doctors joined hands, under the leade ship of Dr. James Kerr (an Irishman who ha served in the Ashanti campaign under Sir Garn Wolseley, a friend of Osler and Shepherd of McGil and a disciple of Lister), and obtained from th Provincial Government a charter for the foundin of the Manitoba Medical College. The openin lecture was given on the evening of Nov. 15t 1883, by Dr. Kerr, who had been chosen Dean. Th first enrolment was of 15 students, and for its fir session the College had no settled place of abod with the exception of a dissecting room, establishe in a cottage on the edge of the city. When mo accommodation was needed, the members of th Faculty subscribed the funds required for the pr vision of a larger establishment. The first graduatin class, in May, 1886, numbered six. To-day th total number of graduates is close upon 1200, whom 800 are practising in Western Canada.

But the story of Manitoba Medical College is mo than a story of bricks and mortar, of statistics enrolments and of graduating classes. From i beginning in 1883 it was a proprietary institutio until 1919, when the medical practitioners, who we its proprietors, handed over to the University Manitoba all its property and equipment, of whic the value was about $250,000, as a gift, "on conditio that the University established a Faculty of Medicin and carry on the work of medical education in a efficient manner." With the completion in 1922 the building programme, and with the enlargemer of the teaching staff made possible by the endowmer fund provided for the Medical Faculty by th Rockefeller Foundation, the University of Manitob now provides undergraduate medical instruction an training equal in all essentials to that given in oth Canadian universities, and with an assured certaint of progress in accordance with the advance in moder educational methods, and of constantly widenin opportunities for medical research.

WINGFIELD ORTHOPÆDIC HOSPITAL.—The annu report of this hospital of the Berks., Bucks., and Oxo Association for the Care of Cripples (130 beds, thr private wards) states that the number of patients the institution increased by nearly 20 per cent., and th number of new patients attending at the clinics by ov 30 per cent. All the beds have been continuously fu and the total number of patients treated was 537. Mo beds are urgently needed, and it is proposed to erect fo open-air wards of 20 beds each at a cost of £12,000. On half of this new accommodation will be for adult patient which will make the hospital unique among orthopæd institutions. The workshops and training schools obtain three first prizes at the International Cripples Exhibitio at Exeter.

THE ANTIRACHITIC VITAMIN D.

ANNOUNCEMENT OF A STANDARD BY THE MEDICAL RESEARCH COUNCIL.

THE Medical Research Council's Committee on ccessory Food Factors have long attempted to find nerally acceptable conventions for the quantitative cord of the activities characteristic of the different cessory factors, or so-called vitamins. As in other stances, however, any unit of activity based on the oduction of a stated degree of a biological effect, owever carefully this may be defined, must be liable wide variation with differences in the conditions der which the test is conducted. This is especially in testing for a vitamin action, where the effect on hich measurement is based is the correction of an normal condition produced by a deficient diet. he severity of the condition to be treated will vary ith differences in the dieting and treatment of the perimental animals, as well as with racial and dividual differences in the stocks. Other bio- gical standards, such as those for sera, hormones, c., held by the Council's Department of Biological andards, are based on stable standard materials, terms of each of which a unit of activity is defined hich is independent of the details of the biological ethod used in its measurement. Here a measure- ent of activity in units is made on a strictly compara- ve basis, with reference to the standard.

NEED FOR A BASIS OF MEASUREMENT.

With regard to one of the vitamins, the anti- chitic vitamin known as Vitamin D, this necessity r a common material standard was recently nphasised in the following recommendation by the mmittee :—

> Any unit or standard based directly on the response of e experimental young rats to administration of anti- chitic material is unsatisfactory, owing to the dispro- rtionate variation in the response to equal doses of parently similar animals, when tested at different seasons the year or bred in different laboratories. The Vitamin D nit should rather be referred to a stated quantity of some andard antirachitic material, with which comparison can e made by any reliable biological method.

The discovery of the method of producing this itamin artificially from ergosterol has led to its anufacture on a large scale, its issue in many forms r therapeutic use, and its addition to various pes of food materials. The proper desire of manu- cturers to use and to supply such preparations with quantitative indication of activity has led to the ppearance of several unofficial "units," mostly efined in terms of some biological effect, and having o clearly determined relation to one another. The eed for a common basis of measurement is, therefore, ccentuated, in this case, by an existing and growing nfusion. One of the provisional units current in is country—namely, that adopted by the Pharma- utical Society's Laboratories when reporting on e Vitamin D content of materials submitted to them r assay, has, indeed, been based on a material andard consisting of an oily solution of irradiated rgosterol, supplied to them for this purpose by the ational Institute for Medical Research. Only a nall quantity of this material had been prepared, owever, and sufficient data were not available to stify the assumption that it would have the stability necessary for a standard and allow the Committee to recommend it for general use.

PREPARATION OF THE NEW STANDARD.

It was accordingly decided to arrange for the preparation by the National Institute of a similar solution, on a scale sufficient for its eventual distribution to the numerous laboratories or institutions likely to require it, and to organise an investigation of its properties by different experts working on behalf of the Committee. A quantity of ergosterol from yeast, purified and dried by methods carefully recorded was subjected, in an accurately made alcoholic solution, to irradiation with the rays from a mercury arc, the physical details of the procedure being measured and recorded with the greatest practicable accuracy. All conditions known to influence the amount of Vitamin D formed should, therefore, be reproducible at any future date, or in any other laboratory, leaving only the final adjustment of a new standard to equivalence with this original one to be made on the basis of comparative biological assay. The irradiation products were carefully freed from alcohol, dissolved in pure, unadulterated olive oil, and the volume adjusted to produce a known concentration, in terms of ergosterol used. The solution was then placed, and its main bulk has since been kept in the Institute's refrigerating chamber at a temperature of −4° to 0° C.

TESTS OF STABILITY.

Evidence of the stability of such a preparation, under different conditions and over a sufficiently long period, being of central importance for a decision as to its use as a standard, the investigations promoted by the Committee have, of necessity, been of a corresponding length. The experimental results from the different contributing laboratories have recently been completed, and have now been carefully reviewed by the Committee, who have stated their conclusion from them in the following terms :—

> From these tests it appears that specimens of irradiated ergosterol, prepared in the manner described above, do retain their activity unchanged for two years if maintained at or below 0° C. If they are kept at room temperature loss of activity may occur.

COMMITTEE'S RESOLUTIONS.

The evidence of the different investigators being uniformly favourable as to the suitability of this solution in other respects for use as a standard in comparative biological measurement of Vitamin D the Committee decided to recommend its adoption as a standard, and the definition of a unit in terms of it, and adopted the following resolutions :—

(*a*) That the standard solution of irradiated ergosterol prepared and maintained by the National Institute for Medical Research be recommended for adoption as a standard for the comparative estimation of Vitamin D.

(*b*) That the unit of Vitamin D be defined as the anti- rachitic potency of a quantity of this preparation corresponding to 0·0001 mg. of the ergosterol used in its production.

(*c*) That either the X ray method, the "Line test," or chemical analysis of the bones of the experimental animals, be recommended for use in the estimation of Vitamin D.

(*d*) That supplies of the standard material be made available for general distribution from the National Institute for Medical Research, Hampstead. As the supply is limited it is hoped that users will themselves prepare standard solutions of irradiated ergosterol for use in individual tests, retaining the National Institute's material for reference. It is important that all such standard materials be kept at temperatures not exceeding 0° C.

THE PROPOSED UNIT.

It may be mentioned that the unit recommended has the same value, in terms of the weight of the original ergosterol represented, as that used for some years past in the Pharmaceutical Society's Laboratories, on the basis of the provisional standard solution supplied to them. The standard solution now recommended for general use cannot be assumed to be exactly equivalent to this, though comparative tests have not revealed a measurable difference. Apart from such difference as may exist, the unit now proposed, will, therefore, correspond to one of those already current. It is of convenient size, as representing the order of dose required for daily administration to a rat, to produce healing of rickets in a curative test; that is to say, the daily dose suitable for the conditions of a particular test will be neither a large multiple nor a small fraction of the unit proposed.

The Committee mention three biological methods of estimating antirachitic effect, which they are able to recommend. Their recommendations on this matter are obviously not meant to be exclusive. They have mentioned the methods in which, from experience of their own investigations, they have confidence, but their statement is not intended to preclude the use of other biological methods that already exist, or of better ones that further investigation may produce, provided that in every case the test is based on a comparison with the fixed standard.

DISTRIBUTION OF THE STANDARD.

As indicated in another of the Committee's recommendations, the quantity of the standard solution available will not allow it to be circulated in large quantities. Its distribution will, of necessity, be limited to those institutions which have the staff and equipment needed for its accurate application in biological assay, including proper facilities for its preservation without loss of activity. Unless the number of institutions requiring it prove to be much greater than that to which other standards are distributed, it should be possible to supply samples once or twice a year to each regular recipient for some years to come, before the preparation of a new batch of the standard solution will be required. It is proposed to make the first issue about the end of September of this year, and a memorandum giving details for the use of the standard will be sent with each first sample. It will greatly facilitate the completion of arrangements if applications from institutions wishing to receive the standard are made as early as possible, so that the Department may be able to estimate the number of separate samples likely to be required for the first and subsequent issues. All such applications should be made to the Director of the Department of Biological Standards, National Institute for Medical Research, Hampstead, London, N.W. 3.

THE PRAISE OF HINDU CUSTOMS.

IN the June number of the *Medical Review of Reviews*, published in Calcutta, Dr. Naliniranjan Sengupta takes us to task for some criticisms of Hindu customs which appeared in an annotation on conditions of childbirth in India in THE LANCET last year.[1] The main propositions in our survey, however, have long been conceded by Indian reformers themselves, and notably by Mr. Gandhi. We agree with Dr. Sengupta that there has been a tendency recently to leave out the economic factor in discussing this and similar questions, and that much of the ill-health in India is due to poverty; but when he proceeds to argue in favour of purdah and child marriage, on the ground that they are safeguards against syphilis and can apparently find nothing to criticise adversely in the present customs, we may safely leave him to his own more enlightened countrymen. There is, however, another side to Dr. Sengupta's argument and a very interesting one. He protests that at the present time it seems impossible for an Englishman to find virtue in any Indian custom, and proceeds to give an account of certain time-honoured practices based on rules laid down in the old Hindu scriptures which are often admirable. Dr. Sengupta holds that some of the maligned social customs have actually done much to preserve the population under conditions which, if not mitigated in any way, might easily have proved fatal. Considering the chronic state of semi-starvation in which many of the Indian people habitually live, he ascribes their comparative immunity from rickets in many parts of India to the immemorial custom of rubbing infants with oil and exposing them at intervals to the sun's rays. Similarly, he believes the low incidence of gastro-intestinal diseases in children, noted in a recent report of the health officer of Calcutta, to be due to the very ancient practice, which used to be almost universal, of boiling the household milk immediately on receipt. It is true also that the ancient scriptures of the Hindus inculcate habits of cleanliness which, however perfunctorily they may be kept up by many devotees to-day, are far in advance of the practice of most Western races. The rules insist on the early morning bath, the habitual use of a fresh toothbrush (consisting of a twig of the neem tree), careful washing of the hands before and after meals, and ablution after visits to the latrine. Specific rules are, moreover, laid down for periodic sexual abstention; intercourse is forbidden during menstruation and pregnancy for several weeks after parturition, and at various other stated times. Dr. Sengupta justly adds that there is much that is admirable in the family life of his co-religionists, and quotes the late Sir George Birdwood, I.M.S., who praised the Mahratha Brahmin ladies as perfect daughters, wives, and mothers whose virtues were deeply rooted in religious convictions. Dr. Sengupta contends that certain factors in the deterioration of the health of the Indian people are of European introduction. Syphilis, he says, comes from abroad, and is accordingly known as the "feringi" (foreign) disease. The adulteration and impoverishment of foodstuffs is regarded as the direct outcome of so-called civilising influences, the modern milling of rice, and blending of ghee with vegetable products having deprived the people of their vitamins. There is something to be said from his point of view, but when he blames Europe unconditionally for malaria he is going too far. To state that this disease was practically unknown in India before the 'sixties of the last century is a grotesque exaggeration which leads one to suspect the accuracy of more reasonable statements. The fact that malaria has been spread by otherwise beneficent railway and irrigation schemes is one of the tragedies which are liable to attend any efforts to improve communications and to safeguard the country against famines, but in working out plans for the future it ought to be possible to minimise this danger. Dr. Sengupta is a staunch upholder of everything Indian, but like so much of the pro-Indian propaganda at the present time, his article makes no attempt to give credit where credit is due.

[1] THE LANCET, 1929, i., 140.

ST. PETER'S HOSPITAL.—Last year 589 patients were admitted to the wards of this Covent Garden hospital for stone and other urinary disesases. It is the only institution of the kind with a supply of radium. A long lease of premises nearly opposite the hospital in Henrietta street has been acquired, and a pathological department has been established there. The hospital itself is being re-arranged and modernised.

OBITUARY

ARTHUR ROBERTSON BRAILEY, M.Chir. Camb., F.R.C.S. Eng.

Surgeon-Captain Brailey, who lost his life when the yacht *Islander* foundered last week on the Cornish coast near Fowey, was younger son of the late Mr. W. A. Brailey, ophthalmic surgeon to Guy's Hospital, and brother of Mr. W. H. Brailey, whom he followed at Westminster School, Cambridge University, and Guy's Hospital. At Cambridge he was minor and foundation scholar of Downing College. Qualifying in 1903, and becoming F.R.C.S. Eng. and M.Chir. Camb. in the following year, Arthur Brailey himself specialised in ophthalmology, and held the post of clinical assistant in the eye department at Guy's before he went to China, where he acted as general and ophthalmic surgeon at Chinkiang Hospital. During the war he was consulting ophthalmic surgeon to the Royal Air Force and surgeon-captain in the Royal Naval Volunteer Reserve, rising to the position of senior medical officer to its London Division, and hon. surgeon to the King. Surgeon-Captain Brailey was only 52 years old at the time of his tragic death, but had already retired from practice to leave more time for his favourite pursuits of farming and yachting.

HUGH COLLIGAN DONALD, M.B., C.M. Glasg., F.R.C.S. Edin.

Dr. Hugh Donald, who died in Paisley on August 24th after an operation, was 60 years of age and one of the most distinguished practitioners in the West of Scotland. He came of a medical family, his father and two brothers also being in practice. Qualifying in 1891 and taking the higher surgical diploma in 1897 after an assistantship in the Leeds school, Dr. Donald obtained an unusual number of appointments, including that of surgeon to the Alexandra Infirmary, Paisley, consulting surgeon to the Royal Victoria Eye Infirmary, and to the Johnstone Hospital. During the South African War he was civil surgeon in charge of the 3rd Cavalry Brigade Composite Regiment Field Force, and returned with the Queen's Medal and four bars. He had a volunteer commission in the territorial army, and during the late war he acted as senior medical officer to the A. and S. Highland Brigade, carrying out much useful work in establishing hospitals in France. When the new venereal diseases clinic was established in Paisley Dr. Donald became surgeon in charge, and later added the Greenock clinic to his work. His all-round competence, we are told, gained him the confidence of medical colleagues, who appreciated his readiness to help new developments.

FREDERICK GEORGE LLOYD, M.R.C.S. Eng.

Dr. F. C. Lloyd, whose death took place in Kensington on August 6th, was in his sixty-sixth year. Although his health had been failing for some years the serious breakdown of his heart a fortnight before he died was quite unexpected. Son of Major Edward Lloyd and grandson of Sir Robert Stanford, Frederick went to the City of London School and followed his brother Rickard as a student at St. Bartholomew's Hospital, qualifying in 1892. Four years later he was in medical charge of the *Harlech Castle* on its voyage from Natal to Plymouth, bringing back 300 sick and wounded men after the Jameson raid. During the South African War he was first attached to the Brigade of Guards Hospital in London, and then civil surgeon in the Field Force, receiving medal and clasps. During the latter part of the late war he was medical officer to the late Lord Dunraven's yacht *Grianaig*, which was placed at the disposal of the Government. A regular attendant and sometime vice-president at meetings of the West London Medico-Chirurgical Society, he frequently took part in its discussions; a paper on Diseases of the Appendix Vermiformis and their Treatment, read in 1904, was his first contribution to a subject he made particularly his own. More recently he opened a discussion on the interim report of the Consultative Council of the Ministry of Health on Medical and Allied Services, in which he took a deep interest. For many years he practised in Kensington, where he shared a house with his brother. He was buried in Hove Cemetery, the vicar of Barnes Church, which for many years Dr. Lloyd regularly attended, officiating.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED AUGUST 16TH, 1930.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 95 (last week 86); scarlet fever, 1534; diphtheria, 969; enteric fever, 73; pneumonia, 478; puerperal fever, 61; puerperal pyrexia, 130; cerebro-spinal fever, 11; acute poliomyelitis, 25; acute polio-encephalitis, 2; encephalitis lethargica, 12; continued fever 2; dysentery, 4; ophthalmia neonatorum, 117. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on August 19th–20th was as follows: Small-pox, 183 under treatment, 3 under observation (last week 209 and 2 respectively); scarlet fever, 1669; diphtheria, 1873; enteric fever, 34; measles, 174; whooping-cough, 80; puerperal fever, 22 (plus 11 babies); encephalitis lethargica, 121; "other diseases," 26. At St. Margaret's Hospital there were 12 babies (plus 7 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 2 (1) from enteric fever, 7 (1) from measles, 5 (1) from scarlet fever, 11 (3) from whooping-cough, 29 (10) from diphtheria, 42 (10) from diarrhœa and enteritis under two years, and 16 (1) from influenza. The figures in parentheses are those for London itself.

The death from enteric fever outside London occurred in Sheffield. No great town reported more than two deaths from diphtheria, or more than one from whooping-cough or measles. Birmingham and Manchester each reported 4 deaths from diarrhœa, Bolton and Sheffield each 3, West Ham, Plymouth, and Liverpool each 2.

The number of stillbirths notified during the week was 284 (corresponding to a rate of 38 per 1000 births), including 55 in London.

VICTORIA INFIRMARY, NEWCASTLE-ON-TYNE.—The 179th annual report, which covers the year 1929, shows that 14,460 in-patients were admitted; they stayed on an average 15 days. Surgical cases numbered 8583, and the gynæcological department dealt with 1442 cases. There were 132,358 out-patients, an increase of more than 3500. The 572 beds were every day insufficient, and although the waiting list has been carefully reviewed at the end of last year it still contained 2603 names, the highest, with the exception of one occasion, yet reached. More than 22,000 accidents were treated, 1470 of which were the direct result of motor traffic. Of these patients 436 were detained and, computed on the average length of stay, they were responsible for the occupation of 20 beds each day throughout the year. Since 1925 the number of motor accident patients has more than doubled. The Nurses' Home has been extended to accommodate 150 nurses, and three of the wards formerly occupied by pensioner patients are to be used for the provision of 86 pay beds.

Appointments

St. Thomas's Hospital: HILL, H. GARDINER, M.D. Cantab., F.R.C.P. Lond., Physician in Charge of Out-Patients; BOGGON, R. H., M.B., B.S. Lond., F.R.C.S. Eng., First Assistant to the Surgical Unit; STEWART, H. H., M.B., B.Chir. Cantab., F.R.C.S. Eng., Registrar to the Surgical Unit; BELL, A. D. C., B.M., B.Ch. Oxon., Registrar to the Children's Department (Medical).

Vacancies

For further information refer to the advertisement columns.

Albert Dock Hospital, Connaught-road.—M.O. At rate of £110.
All Saints' Hospital for Genito-Urinary Diseases, Vauxhall Bridge-road, S.W.—H.S. At rate of £150.
Barnstaple, North Devon Infirmary.—Res. M.O. At rate of £150.
Barrow-in-Furness, North Lonsdale Hospital.—Two H.S.'s. Each £175.
Bath, Royal United Hospital.—Asst. H.S. At rate of £120.
Bedford County Hospital.—H.S. £175.
Blackburn Royal Infirmary.—Third and Fourth H.S.'s. £175 and £150 respectively.
Brighton, Royal Sussex County Hospital.—Cas. H.S. £120.
Bristol Royal Infirmary.—Asst. for Cancer Research Laboratories. £400.
Burslem, Haywood Hospital.—Res. M.O. £175.
Cancer Hospital, Fulham-road, S.W.—H.S. At rate of £100.
Cardiff City Mental Hospital, Whitchurch.—Post-Graduate Research Studentship. £100.
Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C.—Hon. Asst. Anæsthetist.
Chesterfield and North Derbyshire Royal Hospital.—H.S. At rate of £100–£175.
City of London Maternity Hospital, City-road, E.C.—Asst. Res. M.O. At rate of £80.
Colchester, Essex County Hospital.—H.P. £150. Also Asst. H.S. and Registrar. £120.
Derby, Derbyshire Hospital for Sick Children.—Res. M.O. At rate of £150.
Derby, Derbyshire Hospital for Women.—H.S. At rate of £150.
Dreadnought Hospital, Greenwich.—H.P. and H.S. Each at rate of £110.
Eastbourne, Princess Alice Memorial Hospital.—H.S. At rate of £100.
Eastcote, Middlesex, St. Vincent's Orthopædic Hospital.—Res. M.O. At rate of £150.
Edinburgh, Jordanburn Nerve Hospital, Morningside Park.—Asst. Phys. £400.
Gloucester, Gloucestershire Royal Infirmary and Eye Institution.—Second H.S. At rate of £120.
Great Yarmouth General Hospital.—Sen. and Jun. H.S.'s. £150 and £140 respectively.
Halifax Royal Infirmary.—Third H.S. £150.
Hospital for Tropical Diseases, Endsleigh-gardens, W.C.—Two H.P.'s. Each at rate of £150.
Hostel of St. Luke, 14, Fitzroy-square, W.—Res. M.O. £200.
Hull Royal Infirmary.—Hon. Physician.
Ilford, King George Hospital.—Res. M.O. £200.
Ipswich, East Suffolk and Ipswich Hospital.—Cas. O. £150 Also H.S. At rate of £120.
Leeds Public Dispensary.—Jun. Res. M.O. £150.
Leeds, St. James Hospital.—H.P. and H.S. £200.
Leicester Royal Infirmary.—H.S.'s and Cas. O. Each £125.
Liverpool and District Hospital for Diseases of Heart.—H.P. At rate of £52.
Liverpool Eye and Ear Infirmary, Myrtle-street.—Hon. Asst. S. to Ear, Nose, and Throat Dept.
London Female Lock Hospital, 283, Harrow-road, W.—H.S. £150.
London Lock Hospital, 91, Dean-street, W.—H.S. At rate of £200. Also Two Surg. Regs. Each £100.
Macclesfield General Infirmary.—Res. H.S. At rate of £180.
Maidstone, Pembury Institution.—Asst. M.O. £200.
Manchester, Ancoats Hospital.—H.S. At rate of £100.
Manchester and Salford Hospital for Skin Diseases.—H.S. £100.
Manchester, Baguley Sanatorium.—Asst. M.O. £350.
Manchester Joint Committee on Cancer Research.—Asst. in Cancer Research Laboratories. £400–£650.
Manchester, Royal Children's Hospital, Gartside-street.—Two Asst. M.O.'s. At rate of £150.
Manchester, Royal Children's Hospital, Pendlebury.—Res. M.O. and Res. Surg. O. At rate of £125.
Manchester University.—Pilkington Fellowship in Cancer Research. £300.
Manchester Victoria Memorial Jewish Hospital, Cheetham.—Sen. H.S. £250.
Merthyr General Hospital.—Res. H.S. At rate of £150.
Middlesex Hospital, Barnato Joel Laboratories.—Asst. in Radiological Research. £350.
Miller General Hospital, Greenwich-road, S.E.—Cas. O. At rate of £150. Also H.P. and H.S. Each at rate of £125.
National Hospital for Diseases of Heart, Westmoreland-street.—Res. M.O. Also Out-patient M.O. At rate of £150 and £125 respectively.
Northampton General Hospital.—H.P., Two H.S.'s, and Two Asst. H.S.'s. All at rate of £150.
Nottingham, General Hospital.—H.P. Also Second Cas. O. Each at rate of £150.
Oldham, Boundary Park Municipal Hospital.—Res. Asst. M.O. £200.
Oldham Royal Infirmary.—Two H.S.'s. Each at rate of £175.
Plymouth, South Devon and East Cornwall Hospital.—Asst. Pathologist. £350.
Princess Louise Kensington Hospital for Children, North Kensington, W.—H.S. and Cas. O. At rate of £75.
Queen Charlotte's Maternity Hospital, Marylebone-road, N.W.—District Res. M.O., Asst. Res. M.O. Also Res. Anæsthet. Each at rate of £80.
Queen's Hospital for Children, E.—Cas. O. At rate of £100.
Reading, Royal Berkshire Hospital.—Cas. O. and Res. An- thetist. At rate of £150.
Royal Eye Hospital, St. George's Circus, S.E.—12 Salar Refractionists, 12 Clinical Assts., 1 Pathologist.
Royal National Orthopædic Hospital.—H.S. At rate of £150
Ryde, Royal Isle of Wight County Hospital.—Vacancy on H Med. Staff. Also Res. H.S. £180.
St. John's Hospital, Lewisham, S.E.—Res. Cas. O. £100.
St. Paul's Hospital for Diseases of the Genito-urinary Organs, Endell-street, W.C.—Res. M.O. Also H.S. At rate £200 and £150 respectively.
St. Peter's Hospital for Stone, &c., Henrietta-street, Covent Gard W.C.—H.S. At rate of £75.
Salford Royal Hospital.—Two H.S.'s Each at rate of £125.
Sheffield Royal Hospital.—Res. Anæsthetist. At rate of £8
Shrewsbury, Eye, Ear and Throat Hospital.—H.S. £200.
Southampton Children's Hospital and Dispensary for Women Res. M.O. At rate of £100.
South Shields, Ingham Infirmary.—Jun. H.S. £150.
Stafford, Staffordshire General Infirmary.—H.S. and H.P. rate of £200 and £150 respectively.
Stoke-on-Trent, N. Staffordshire Royal Infirmary.—Asst. H.P. £1
Swansea Hospital.—H.S. £150.
Swaziland.—M.O. £500.
Tilbury Hospital, Essex.—H.S. At rate of £150.
Tynemouth, County Borough of.—Asst. M.O.H. £540.
Uxbridge, Middlesex, Hillingdon Institution.—Res. M.O. £60
Victoria Hospital for Children, Chelsea.—H.S. At rate of £1
Walsall, Manor Hospital.—Res. Asst. M.O. £200.
West Bromwich and District General Hospital.—H.P. and C H.S. Each at rate of £200.
West London Hospital, Hammersmith-road, W.—H.P., T H.S.'s., and Res. Anæsthetist. Each at rate of £100.
West Lothian, Bangour Mental Hospital.—2nd Asst. M.O. £3
Willesden Municipal Hospital.—Res. M.O. £250.
Wolverhampton and Midland Counties Eye Infirmary.—H.S. £1
Woolwich and District War Memorial Hospital, Shooters H S.E.—H.S. At rate of £100.
York County Hospital.—H.P. £150.

The Chief Inspector of Factories announces vacant appointme for Certifying Factory Surgeons at Llanybyther (C marthenshire) and Paisley (Renfrewshire).

MEDICAL NEWS

Society of Apothecaries of London.

At recent examinations the following candidates pass in the subjects indicated:—

Surgery.—G. P. Charles, Sidney and Charing Cross Hos; H. G. Edmunds, University College Hosp.; C. W. Ellis, St. Bart.'s Hosp.; E. J. Jones, Cardiff; N. I. Kronenberg, a W. Montgomery Smith, Guy's Hosp.; H. I. Newman, Lond Hosp.; R. D. Newton, St. Bart.'s Hosp.; K. V. Pillai, M chester; L. Sachs, St. Mary's Hosp.; I. J. Todd-Nay King's College Hosp.; and G. H. C. Walmsley, Manchest

Medicine.—H. W. E. Dickey, Manchester; E. A. Freywir Heidelberg; N. I. Kronenberg, Guy's Hosp.; J. M. L. Lo St. Mary's Hosp.; W. Montgomery Smith, Guy's Hos H. I. Newman, London Hosp.; and I. J. Todd-Naylor, Kir College Hosp.

Forensic Medicine.—M. M. Barritt, Manchester; J. S. Coutts, St. Mary's Hosp.; C. R. Graham, Kingston, Ontar M. Halperine, Paris and London Hosp.; N. I. Kronenb and W. Montgomery Smith, Guy's Hosp.; H. I. Newm London Hosp.; W. K. Schnarr, Guy's Hosp.; G. H. Walmsley, Manchester; and I. M. Williams, Edinburgh.

Midwifery.—S. Gurevich, Charing Cross Hosp.; M. Halperi Paris and London Hosp.; E. I. B. Hawes, St. George's Hos W. Montgomery Smith, and W. W. Parry, Guy's Hosp.

The Diploma of the Society was granted to the follow candidates, entitling them to practise medicine, surgery, a midwifery: M. M. Barritt, G. P. Charles, H. W. E. Dick H. G. Edmunds, C. W. Ellison, E. A. Freywirth, N. I. Kron berg, W. Montgomery Smith, I. J. Todd-Naylor, and G. H. Walmsley.

University College Hospital Medical School.

The Goldsmid entrance exhibitions for 1930 have b awarded to Mr. G. Quist and Mrs. M. H. James.

University of Manchester.

Application is invited for the Pilkington Fellowship Cancer Research, of the value of £300, tenable for one ye

University of Aberdeen.

Dr. David Campbell, Pollok lecturer in pharmacolo and therapeutics at the University of Glasgow, has b appointed Regius professor of materia medica in the pl of Prof. Charles Robertshaw Marshall, whose resignati takes effect next month.

Department of Health for Scotland.

Dr. James Law Brownlie, county bacteriologist a pathologist in Lanarkshire, has been appointed a medi officer of the Department. Dr. Brownlie, who graduat in medicine at Glasgow University in 1913, was reside for several years in Glasgow fever hospitals, and was six years assistant bacteriologist in the Glasgow Corporati laboratory.

NOTES, COMMENTS, AND ABSTRACTS

MEASLES CONTACTS:

THEIR EXCLUSION FROM SCHOOL.

By DUNCAN FORBES, M.D., B.Sc., D.P.H.,
MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER FOR BRIGHTON.

MEASLES is one of the most highly infectious of diseases. It starts as a cold in the head and the patient also coughs. He is not usually isolated for the first few days, since his parents do not know what he is suffering from until the typical rash appears. During these days he has been talking and coughing and in so doing has spread all around him a fine spray, the tiny droplets of which carry the infection to those of his companions who inhale them. It is no wonder, then, that practically all children who have mixed freely with other children for two or three years in schools, Sunday schools, creches, and cinemas have had an attack of measles. In towns practically all elementary school-children sooner or later develop the disease; in the country a few escape. The experience in every town is the same and no means have been discovered to control the spread of the disease.

MEASLES MORE DANGEROUS THAN SCARLET FEVER.

The annual average number of deaths for the period 1919–28 was 4500 from measles and 1000 from scarlet fever, so that measles took the larger toll. Although it is thus established that measles is more dangerous to the nation than scarlet fever, this does not mean that measles is more dangerous to the individual attacked. Scarlet fever in typical form attacks a relatively small proportion of the population, whilst very few escape measles; the number of deaths recorded, therefore, has no relation to case-mortality. To impress a mother with the danger of measles by saying that her child is suffering from a more dangerous disease than scarlet fever is therefore wrong, since the mother is apt to think in terms of case-mortality.

It may be argued that if all children who mix freely with their fellows develop measles it is futile to attempt to prevent its spread. But attacks of measles are most dangerous to children from one months to two years old, and thereafter the risk becomes less and less until at school age (five years) and onwards the risk is a very small one. This is proved from figures which show that at the ages 3, 4, and 5) when measles is becoming more and more prevalent the number of deaths becomes fewer and fewer. Not only is measles enormously more dangerous to the very young than to their elders, it is also far more dangerous in the winter than in the summer months. Thus the main objects should be to protect the children under five and if possible to delay epidemics until the summer.

PROTECTION OF THE VERY YOUNG.

There are two creches in Brighton to which the infants and children of mothers who have to go out to work are admitted. Any case of measles occurring in the creches is reported and the creche is closed down for the week during which the secondary cases are expected. If a number are known to have already suffered from measles it is sometimes found worth while to allow them to continue to attend. In spite of the most stringent precautions taken in these and other creches this gathering together of infants and young children leads to the infection and death of numbers of infants and toddlers each year, and the most stringent rules for exclusion and closure are abundantly justified. In the infant department of elementary schools in the presence of measles the Brighton rule is to exclude delicate children and all children under five years of age. Before this rule was introduced I have known of an elementary school-child under two dying from measles; on inquiry I found that no child under three should have been admitted, but that for children under five the mother's statement of age was taken as correct. I have no doubt of the advisability of the exclusion of all children under five.

DELAY OF EPIDEMICS.

When an epidemic begins in November it is customary to prolong the Christmas holidays of the schools infected, not with the object of stopping the epidemic but of checking the rapidity of its spread. This action does not do much good, since the epidemic is again in full swing towards the end of January and in February and March, all inclement cold months. No doubt if infected schools could be closed for, say, six weeks at Christmas, the epidemic, although it would restart on the re-opening of the schools, would be at its height in a town the size of Brighton after the cold weather was over. The Ministry of Health and Board of Education, however, do not favour school closure, which they rightly say only postpones and prolongs an epidemic (Memorandum on Closure of and Exclusion from School). The curious thing is that although it is stated in this memorandum just referred to that the spread of measles cannot be stopped even by complete school closure, very specific advice is given regarding the exclusion of contacts. It would seem that no regard is paid to the fact that if the large measure—school closure—will not stop an epidemic a whole lot of niggling rules about the exclusion of contacts are unlikely to have any appreciable effect; incidentally these rules regarding exclusion of contacts involve much clerical work at health offices and to teachers. The advantage of following the official rules is that the exclusion of contacts gives the impression to the public that all possible steps are being taken to combat the epidemic and meets the criticisms of those who have not studied the subject.

NON-EXCLUSION OF HEALTHY CONTACTS.

What the man in the street cannot understand is why all contacts should not be at once excluded. The chief reason is that they should at all costs be kept as far as possible apart from children under school age. It is many times more important that contacts should not infect any 1–5 year old child of other families than that they should be kept away from classmates who are also contacts and who will be probably infected in any case within the next few weeks. It should also be remembered that the mother has instructions to keep these contacts at home on the slightest sign of cold, and that the class teachers are also on the look-out.

SUGGESTED CHANGES IN ROUTINE PRACTICE.

The exclusion of home contacts attending infected schools should be abandoned. On the other hand, contacts attending uninfected schools should be excluded whether or not a previous attack is reported. Sunday schools are spreaders of the disease from one district to another, children often going to Sunday schools some distance from their homes. It is very important that contacts should be excluded from Sunday school. More use of school closure should be made to delay the spread of an epidemic through a town in the winter months. It should be left to the Medical Officer of Health to judge how school closure can be used with the greatest effect. In this connexion the health authorities should have power to close Sunday schools; they should also have power to close cinemas to children. School closure only likely to delay spread should not be practised in the warm months if thereby the epidemic is liable to be delayed to the winter months.

At all seasons steps should be taken to prevent the infection of the very young by the exclusion of the children under five from school and to ensure the closure of creches in the presence of measles. Careful

inquiry should be made to prove or disprove the case against infant welfare centres as spreaders of measles and whooping cough and "common" colds. Certainly mothers should be not allowed to stay longer than necessary at such centres.

CLASSIFIED EXAMINATION QUESTIONS.

A REPRODUCTION of questions set in medicine, surgery, and midwifery from 1911 to 1929, classified under the various systems and arranged in the date-order of their occurrence, cannot fail to interest students of medicine. Dr. Gerald Beeston [1] found when he was reading for his qualifying examinations that by concentrating separately upon the diseases of the various systems and organs in turn, and subsequently working through a large number of questions set upon a particular system or organ, he obtained a thorough grip of the subject and got through a vast amount of reading. Moreover, by following such a scheme of revision, the more important and everyday aspects of medicine, surgery, and midwifery were emphasised and impressed upon his mind. He decided to give others the benefit of his experience, and prepared a book of questions. While the book is compiled solely from the final examination papers of the Royal Colleges of Physicians and Surgeons of London and England, the scope covered by the questions is sufficiently wide to render it of value to anyone about to sit for any examination for medical qualifications. As an indication of the importance of each subject, questions (which are conveniently grouped under systems or organs or branches of medicine) have been repeated just as often as they occurred. For example, among diseases of the respiratory system questions on pleurisy, pleural effusion, or empyema occur 16 times in the 19 years in medical or surgical papers. Blank lines opposite a year imply that no questions were asked about that section in that year. This and subsequent editions which will be issued from time to time to include the latest questions will have a certain value for the medical historian as well as for succeeding generations of students. He will note with interest that no questions on diseases of the endocrine glands were asked until 1927, that the first question on artificial pneumothorax was put in 1925, and that the first mention of radium in gynæcology occurs in 1926, when insulin therapy also comes into the lists. In this last case, the short period between the time of discovery and the achievement of that degree of acceptance justifying inclusion in a qualifying examination must be nearly a record.

A students' manual of even wider scope [2] has recently been compiled from examination papers set by some of the Scottish licensing bodies. These include not only the final subjects but also questions set in botany, zoology, chemistry, physics, anatomy, and physiology. They are not classified according to subject matter, and are likely to be used mainly by those students who are prepared to work through papers systematically, and by those who wish to practise answering all the questions in any paper in the allotted time.

NATIONAL INSTITUTE FOR THE DEAF.

THE sixth annual report of the Executive Committee of the National Institute for the Deaf, which was taken as read at the annual meeting of the Institute on May 30th, when Mr. Baldwin addressed the meeting (see THE LANCET, June 7th, 1930, p. 1251), has now been published, and the work done justifies the increasing support which is being received by the committee. The immediate aims of the Institute show that the work is national in scope. So much information has been collected proving the existence of social and economic hardship among the deaf that general relief, it would seem, can only be effected adequately by organised public assistance, when clear arguments are forthcoming to induce the Government to make a full inquiry into the situation. A departmental committee, such as was set up in the case of the blind, might well be directed to inquire not so much into the cause and prevention of deafness as into the methods for the education and training of the deaf in all stages of their career. It is more than 40 years since any Government department has made an inquiry into the position of the deaf. The National Institute has been in active operation for only five years, but has during that period done a great deal of useful work. Its hands are tied by lack of adequate funds, the ordinary income being insufficient to meet expenses, and we trust that generously minded people will realise its urgent need. The address of the National Institute is 2, Bloomsbury-street, London, W.C. 1.

DOWSING.

THE dowsing rod for the discovery of subterranean minerals or water has been in use throughout modern civilisation and is associated with the taking of auguries in ancient Rome. The activities of a French priest in this country have recently been mentioned in the daily press and brought the subject up for one of the constant recurrences of discussion, while at the same time "a member of an old French aristocratic family which has been well known in the North of France for six hundred years" has written a little manual which purports to communicate to the reader the principles of dowsing and the ability to make practical use of them.[1] The Vicomte de France, in his volume, departs at once from the methods of the augur, because he is unable, through the nature of things, to display the actual events; he can only describe the technique for employing the virga divina, and publish the results claimed, whereas the augur of old, by actual dissection of the victim, would demonstrate the arrangement and collation of parts on which he depended for his prophecy. Begging the whole question in the first sentence of the book, M. de France states that it is well known that with the help of a hazel rod subterranean water can with certainty be found, when he proceeds to describe the manœuvres which should be employed, protesting that the mysterious semblance which revolted reasonable minds disappears under the informing words. Unfortunately, nothing of the sort occurs, because, whether the divining rod is manipulated under the cloak of magic or employed with what is assumed to be scientific precision, dictated by the laws of physics, the fact still remains that the connexion between the manœuvres and the result is unexplainable. Of course we can acquiesce, if we convinced, in the theory that we are faced with phenomena analogous to those which attend wireless telegraphy; or we can believe that some electric force is involved whose working remains for demonstration. In support of the latter suggestion "the experiments of Abrams, the late celebrated American doctor" are adduced, and we are told that from his work there "has arisen a new method which consists in determining the abnormal vibrating periods of a patient and in re-establishing the normal dynamic while suppressing the pathological vibrations by the use of suitable agents." We doubt whether M. de France will convince many of our readers, by adducing the support of the late Dr. Abrams, that he has placed before them in any scientific manner the explanation of the successes claimed for the dowser. If he has done so, we may join him in thanking "the humble country clergymen of France" whose practical work as water-diviners appears to have led to the writing of this book. But there is no unreasonable scepticism displayed if we withhold this gratitude.

ADDRESSES AND ORIGINAL ARTICLES

THE SYNTHETIC ACTIVITIES OF THE ANIMAL CELL.*

BY H. S. RAPER, C.B.E., D.Sc., M.B. LEEDS, F.R.S.,
BRACKENBURY PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF MANCHESTER.

UNLIKE the chemist, the animal cell has a very limited choice of raw materials from which synthesis must start. These are the components of the common foodstuffs. When they have undergone the preliminary processes of digestion they provide in all about 30 substances which may be regarded as available for the building up of new compounds by the cell. They consist of about 20 amino-acids, two purine bases, three pyrimidine bases, three hexoses, glycerol, and higher fatty acids. It is true that there may be other hitherto undiscovered components of foodstuffs which are important as raw material for synthesis in the animal cell, but they can be but few in number and present in small amount.

Substances Synthetised from Unidentified Raw Materials.

Given this list of raw materials can we indicate which is the likely starting-point for the synthesis of substances whose constitution is known or partly known? This question must still be answered in the negative for such well-known products as cholesterol and the unconjugated acids of bile. It is possible that the experiments of Channon, who demonstrated that addition of spinacene to the diet of rats caused the cholesterol content of the liver to increase to double its usual amount, may afford a clue to the origin of this substance, but it is difficult to conceive of spinacene being the raw material for this synthesis in the herbivorous animal. As for the bile-acids, we are in complete ignorance of the substance or substances from which they are built up. The probable raw material for the synthesis of the purine bases, which are components of nuclear material and therefore present in all cells, must also be answered in the negative, but with less emphasis than in the case of cholesterol and the bile-acids. The amino-acid histidin, which contains a five-membered ring similar to that found in the purine bases, is their most likely precursor on structural grounds. The synthesis of cholesterol, that of the bile-acids, and of purine bases are still problems in the purely chemical sense. When the chemist has indicated their likely solution it will be the task of physiology to find out the mechanism by which the cell brings about the necessary chemical processes.

An example of a synthetic product which bears a fairly close structural relationship to two of the amino-acids which are found in proteins is adrenalin. These two amino-acids, phenylalanin and tyrosin, have practically the same carbon skeleton as adrenalin. Either of them might give rise to adrenalin by successive oxidation, methylation of the amino group, and loss of carbon dioxide. That a part of the necessary oxidation process can be brought about by means of an oxidising enzyme has already been demonstrated. This enzyme, tyrosinase, will oxidise tyrosin to 3:4-dihydroxyphenylalanin. It is, therefore, conceivable that the first stage of the synthesis from tyrosin occurs in this way in the cell. If, however, we consider how we may find out whether a process of this kind, operating in the cells of the adrenal gland under specific conditions, gives rise to adrenalin, many difficulties appear. The discovery of the mechanisms by which adrenalin is formed, although a simple problem at first sight, is probably in reality very complicated.

The case of thyroxin is comparable with that of adrenalin. Thyroxin is a relatively simple chemical substance which could conceivably be produced by the oxidation of diiodotyrosin. The last-named compound has recently been shown to be present in the thyroid gland and this makes the presumption that it is the mother substance of thyroxin all the stronger. Yet it has not been demonstrated either in vitro or in vivo that thyroxin may be produced from diiodotyrosin.

These two instances of adrenalin and thyroxin show that, even when there is a reasonable presumption that we know the raw material from which the synthesis in the cell starts and the chemical processes concerned, the proof that our hypotheses are correct is far from simple.

Substances Synthetised from known Raw Materials by unknown Chemical Reactions.

We may now pass on to consider a process in which the raw material is known with certainty but the chemical reactions by which the synthesis takes place are relatively obscure—the production of fat from carbohydrate. Lawes and Gilbert, in their classical experiments at Rothamsted on the fattening of farm stock, showed indubitably that animals can produce fat from starch. It has been confirmed since by others. Since the starch is converted into glucose in the alimentary canal prior to absorption we may consider glucose as the starting-point of the synthesis.

The evidence for the mechanism of synthesis of the fatty acids from some simple reactive substance which is first produced by degradation of glucose, such as acetaldehyde or pyruvic acid, is purely chemical and the grounds on which it can be put forward are largely chemical ones. Is there any physiological support for this scheme? Studies of the synthesis of fat in animals have yielded very little so far. It is, however, known that acetaldehyde and pyruvic acid, the intermediates postulated in the hypothesis just mentioned, can be produced in the body. When we know what the conditions are which set the process of fat synthesis going, and when we are able to reproduce them at will in animals, it may be possible to determine what are the intermediate substances concerned.

More success has been achieved by a study of the formation of fatty acids in micro-organisms, some of which possess this faculty in a remarkable degree. Bacteria which form butyric acid from glucose have been found to produce in addition both lactic acid and acetaldehyde. These same bacteria will also produce butyric acid from pyruvic aldol though not from aldehyde ammonia, aldol, or pyruvic acid itself. It appears probable that the processes by which these lower members of the series of fatty acids are formed in bacterial fermentation may be the same as those by which higher members of the series are formed in animals. The production of fat is a process which is common to a great variety of living organisms, both simple and complex, animal and vegetable. It is not

* Abridged from an address delivered to the section of Physiology of the British Association for the Advancement of Science on Sept. 4th.

unlikely, therefore, to be carried out by the same series of chemical reactions wherever it is found. It may be that we shall eventually discover the reactions responsible for the synthesis of fat in animals by investigating the processes by which it occurs in vegetable forms, such as bacteria or moulds.

Syntheses from known Raw Materials by partially known Chemical Processes.

We have also to consider how the synthetic product is dealt with in the cell so as to protect it from the disruptive agencies which exist there. Arrangements for this purpose must be present, since we know that substances may accumulate in cells which contain enzymes that hydrolyse them. For example, fat and lipase coexist in the liver cell and also glycogen and amylase. The phenomena of autolysis illustrate the same fact too. Whatever these arrangements are, they appear in certain instances to be closely associated with the life of the cell, for after death they cease to operate and the synthetic product is again broken down. However difficult it is to form a conception of them it may be necessary to do so, since they must form a part of any system which is put forward to explain synthesis as a result of the intervention of surface phenomena.

There is little or no doubt about the raw materials or some of the chemical reactions involved in the production of glycogen and of proteins.

Glycogen, which has the empirical formula $C_6H_{10}O_5$, has recently been shown to be constituted like starch on the basis of continuous maltose units, or, what amounts to the same thing, a conjugated chain of α-glucose units. It has also been proved that when glycogen breaks down in the liver it gives rise to glucose. Recent work suggests that there may be some configurational difference between glycogen and starch which accounts for their difference in behaviour with diastatic enzymes. Be that as it may, it appears natural to assume that the synthesis of glycogen from glucose in the cell is brought about by the simple reversal of a hydrolysis which may be catalysed by enzymes under appropriate conditions. These conditions have, however, not yet been realised in vitro.

The failure to obtain evidence of the synthesis of glycogen from the products of its hydrolysis makes it legitimate to consider whether we are right in adopting the orthodox view that the synthesis of glycogen from glucose in the living cell is brought about by a reversal of action of the enzyme or enzymes which hydrolyse it.

A consideration of all the data which have been accumulated regarding the synthesis of glycogen makes it probable that more than the mere reversal of enzyme action is concerned. It is certain that the cells in which it occurs must be supplied with oxygen. Fletcher and Hopkins also showed with muscle that its structure must be maintained and with liver the synthesis certainly only takes place in the intact organ. Do not these facts point to the conclusion that it is only the living cell that can bring about this synthesis? And if this be so, cannot we go further and suggest that the substances from which glycogen is produced or bodies derived from them must first become bound up with or at some stage form an integral part of the living structure before they are converted into glycogen. The evidence at least suggests that some such conception of the process may not be far from the truth.

Proteins.—In the early part of this century rapid advances were made in our knowledge of the structure of proteins. These advances led to a picture of protein structure which has become generally accepted —namely, that the protein molecule is formed b the union of amino-acids through an amide linkag It is, however, unlikely that this is the only bond union between the amino-acid units. If it were, th widely different physical and chemical properti which are met with in the proteins would have to b explained largely on the basis of their amino-ac content. The differences in composition which the exhibit do not seem to be sufficiently great to warra this assumption. The insolubility of the keratins, f instance, although accounted for in part by the hig proportion of cystin they contain, this being a ver insoluble amino-acid, is possibly also due to th presence of other modes of union of the constituer amino-acids in addition to the amide linkage. Sim larly, the varying degree of liability, the phenomer of denaturation, and the physicochemical behavio of different proteins are difficult to explain solely o a basis of differences in their components. There much still to be learnt about the actual structure the protein molecule.

The investigation of the structure of proteins whi are closely allied in origin, composition, and gener chemical behaviour by immunological and in part b chemical methods has taught us how intricate th mechanism must be by which they are built up. Th facts brought out by the classical work of Dakin an Dale on the albumin of the duck's and hen's eg serve to exemplify this.

The only chemical difference that could be shown betwe these two proteins was concerned with the disposition the molecule of some of the leucin, aspartic acid, an histidin, which resulted in different degrees of racemisati of these amino-acids when the respective albumins we treated with caustic soda. But when used as antigens the anaphylactic reaction they were markedly specif These results indicate that the stereochemical structure the molecule is different in proteins which are very simil both in general chemical properties and in biological orig They suggest that the protein molecule produced by particular type of cell is always built up in a distinctive an so far as we can determine, an unvarying pattern.

We may deduce from this that although the gener method of protein synthesis, that is to say, th mechanism by which amino-acids are joined up, ma be the same in all cells, yet there must be arrang ments in the cell which enable only one particula final pattern, to result from the synthesis.

THE METHODS WHEREBY AMINO-ACIDS COMBINE.

What are the methods by which the amino-aci are caused to combine? Those used by the organ chemist in the synthesis of polypeptides can have n place in the living cell, although they have been great assistance in helping to reveal the gener structure of proteins. The use of proteolytic enzym in an attempt to bring about synthesis under cond tions which have been partially successful with oth substances has often been tried and nearly as ofte has failed. Two examples of protein synthesis b enzyme action have been described. The mo acceptable of these is Taylor's production of a pr tamine by a glycerol extract of clam liver from th products of its complete hydrolysis. But, so far a I am aware, this is an isolated observation whi has not been extended or repeated with other pr tamines. The other is the preparation of so-calle plasteins from the products of the partial hydrolys of certain proteins by pepsin. A comprehensiv review of the subject of plastein formation b Wasteneys and Borsook, who have themselves mad notable contributions to this problem, has led the to the belief that in this phenomenon we have a tru resynthesis of protein from some of the more comple of its hydrolytic products. Their work still leav

many questions regarding protein synthesis nanswered, and not the least difficult of these is the roblem of how the separate amino-acids are brought ogether to form the specific proteose substrates hich one must postulate as combining—and in a efinite order—to produce the particular protein hich is characteristic of the cell which synthesises it. ne of the great difficulties in accounting for the nthesis of protein by a reversal of enzyme action that this synthesis only takes place, so far as we n observe, in a cell which is living.

The process by which the substance of the cell is creased, the building up of protoplasm, is one which ust be closely allied to protein synthesis, since the aterial we call protoplasm is constituted for the eater part of amino-acids, united, so far as can be certained, by the same sort of linkage that we find proteins. The protoplasm of the dead cell responds all the tests by which we identify protein, it is bject to the action of hydrolytic agents in the same ay, and yields identical products when hydrolysed. ught we not therefore to look for some of the echanisms of protein synthesis in the processes nich operate when the living cell grows, and can by any stretch of imagination account for this by reversal of the action of one or more hydrolytic zymes? It appears inconceivably difficult to do . The extreme specificity of the reaction which cessitates that at a given phase of the synthesis e particular amino-acid and that one alone can be ded as the next link in the molecule, requires such multiplicity of enzymes and such a remarkable gree of control of their action as to be almost tside the range of probability. When we remember, lwever, that one of the prime attributes of life is at it is a dynamic condition, it does become possible t form a conception of protein synthesis in relation t that fact. The experiments of Willstätter and ners have shown that to some extent the specificity enzymes is accounted for by the "carrier" with ich they are associated. It is not inconceivable t a catalyst capable of bringing about the union amino-acids in the living cell and ultimately f hioning its protoplasm may be attached to or a ociated with a "carrier" which, instead of having a ixed configuration, as with the enzymes that we e extract from the dead cell, has one which is con- tually varying, this dynamic state being charac- tistic of the living material of the cell.

f, further, we could assume that the variations in ti configuration of the carrier were cyclic, always g ng through a definite series of phases, it might be p sible to account for the fact that at any particular p se of the cycle the configuration would be such a to favour the synthetic union of one particular a ino-acid rather than any other because of its s tial arrangement. The assumption of cyclic c nges in simple or complex living organisms is not n in physiology, and it is not unlikely that they o r in parts even of the cell itself. The phenomena o nitosis are a somewhat gross illustration of such c lic events.

A POSSIBLE MECHANISM OF SPECIFIC PROTEIN PRODUCTION.

s is perhaps difficult to justify speculations of this ki l, but it appears to me that it is at least useful as n intellectual exercise to try to arrive at some co eption, founded on what little experimental ev ence we at present possess, of a possible mechanism wh h would account for the reproduction time after ti of the intricate pattern of the protein of a pa icular type of cell.

Whatever be the mechanism of protein synthesis there is another fact concerning it which is of interest, and that is that the cell to maintain itself must apparently contain a certain concentration of amino-acids. If these are not supplied in the animal's food then the animal supplies them by maintaining its more important tissues at the expense of others. This would suggest that the conditions for nitrogeneous equilibrium which we find in the whole animal have their replica in each cell, but the concentration of amino-acids required to maintain the equilibrium is not the same for all. Hence an amino-acid deficiency such as occurs in protein starvation leads to autolysis of some tissues before others. The equilibrium conditions appear to be set at different levels. The fact that certain amino-acids are more necessary than others in providing for this balance may be partly due to their special importance in the protoplasm of those cells which are the first to break down when protein food is withdrawn or an inadequate protein is fed.

The Site of Protein Synthesis.

The possibility that protein synthesis is associated with some part of the cell which is undergoing cyclic changes, and is thus alive, raises the interesting question of the site of this and possibly other syntheses, such as those of fat and glycogen. Are all parts of the cell—that is to say, both nucleus and protoplasm, to be regarded as alive in the sense I have indicated, and therefore to be considered as regions in which syntheses depending on life can be brought about?

It is necessary not to confuse the terms irritability and life. It is true that what we term irritability is usually taken to imply that the tissue which shows it is living, but taking the nerve-fibre as an example, it would appear that the maintenance, for a time at least, of the irritability of protoplasm and its restoration when it has disappeared—but not irreversibly—does not require the presence of the nucleus. It may require oxygen or the presence of certain ions, but this may merely mean that the labile state of the protoplasm has been upset by the products of the cell's activity, and removal of these will restore it to its irritable condition.

IRRITABILITY AND LIFE.

We have no evidence that irritability as a manifestation of what we call life is more than the possession of extremely labile structures, sensitive to minute environmental changes. The nucleus, on the other hand, is essential to the continuous life of the cell and its growth. It appears also to determine very largely the magnitude of the respiratory processes which occur in it at rest, though not necessarily the excessive respiration observed in the recovery from functional activity. Can we therefore go so far as to say that the nucleus is the seat of those synthetic activities of the cell which appear to depend on its living character rather than on its irritability, or have we to regard the protoplasm as equally living so that it is able to reproduce itself and in addition bring about such syntheses as those of fat and glycogen?

There is something to be said in favour of the idea that the protoplasm is not living in the sense in which the nucleus is, and therefore is less likely to be the seat of certain synthetic processes. It is, I think, quite a tenable view that protoplasm is made up, largely but not entirely, of combinations of amino-acids such as we find in the proteins, and that it is synthesised by the nucleus to serve special as well as certain general requirements. These special requirements must and do vary greatly with each type of cell.

Consider the mammalian erythroblast. The principal substance in its protoplasm is the protein hæmoglobin. It is doubtful whether this cell exists except to produce hæmoglobin. When it has matured the nucleus degenerates and disappears leaving the red blood corpuscle. Along with

this the respiratory activity of the cell practically disappears too, and there is not much discoverable in it except hæmoglobin. It is certainly now not living in the sense in which its progenitor, the erythroblast, was. Is it not reasonable to suggest, therefore, that the production of hæmoglobin as the erythroblast grows and matures is a function of the nucleus and not of the protoplasm of this cell? All semblance of further synthesis of hæmoglobin certainly disappears when the nucleus goes. The adoption of such a view does not imply that having produced the protoplasm of a cell the nucleus has nothing more to do with it. We know that in some indefinable way the nucleus in most cells controls the structure of the protoplasm and maintains its lability, but we have no knowledge as yet of the mechanism by which this is brought about.

In emphasising the great similarity between the growth of protoplasm and the synthesis of proteins, other examples in addition to that of hæmoglobin come to mind. The cells of the Malpighian layer of the epidermis have to produce the protein which eventually becomes the keratin of the *stratum corneum*. This would appear to be one of their chief functions. When it is done the cell dies and the nucleus becomes functionless. The production of collagen by cells of the connective tissue and of milk proteins by the cells of the mammary gland are instances of the continuous synthesis of proteins which are not labile like the protoplasm of, say, the muscle or nerve cell. Their formation, however, may be due to the operation of the same general process. They are certainly non-irritable and non-living. It is difficult to imagine that while in the cell they possess the power of reproduction but lose it once they have been cast out.

NUCLEUS OR PROTOPLASM.

If we accept the possibility that the nucleus of the cell may be the site of protein synthesis it is legitimate to consider whether the substances which appear in the protoplasm as discrete particles or masses such as glycogen or fat are produced in the nucleus or only in the protoplasm. We have no evidence as to this. The fact that they first appear as visible objects in the protoplasm is not evidence that they were produced there, and it has already been pointed out that their synthesis is apparently only possible in cells which are alive. They may be synthesised in the nucleus and stored in the protoplasm. Their disappearance from time to time may be conditioned by the liberation of enzymes from the nucleus to hydrolyse them. Such a view would do away with some of the difficulties which we experience in attempting to explain why substrates may be present in cells which, judged by their behaviour after death, appear to contain enzymes that hydrolyse them. The proto, plasm, instead of producing such reserve materials may serve as a convenient storehouse for them until the appropriate stimulus for their breakdown arrives.

One property of proteins, which may account in a general way for the presence of protein-like structure in protoplasm, is their buffering power. The nucleus is probably the most labile part of the cell. The chemical reactions proceeding in it may demand an environment that has to be finely controlled as regards changes in reaction or the concentration of certain ions. The protoplasm may thus serve as a protective layer between the nucleus and the external world, guarding it from changes which would otherwise terminate its existence. The known properties of the proteins, both chemical and physical, may be useful to this end, to which they are almost ideally suited.

Even if we can accept as possible the unorthodox view that the nucleus is the only living part of the cell, and is therefore the only part that can bring about syntheses which depend upon life, it does not solve our difficulties in explaining how they are achieved. It merely narrows down the possible sites in the cell in which they occur. The nucleus itself is a complex structure, and we have as yet few experimental methods for elucidating it. Most biologists would, I think, agree that the cell has arisen by process of evolution from something simpler ar eventually from non-living materials. It cannot ha come as a "bolt from the blue." If we regard t nucleus as the only living part of the cell, then v may justly regard the protoplasm as something th has been acquired or developed in the process evolution and is now necessary to its existence. W do not know definitely, however, of nuclear materi which is living and devoid of its protoplasmic envelo unless such an arrangement is present in the bacter But the investigation of filtrable viruses has giv an indication that material possessing the prir attribute of life—namely, the power of reproduci itself—exists, possibly in simpler forms than we fi in the smallest visible organisms.

If we agree that the cell has evolved from son thing simpler, then we might expect to find su elementary forms of life coexisting with it did but know how to look for them. The filtral viruses may represent such forms, and their chemi characters may resemble those that we find in t nucleus of the cell. The ability to synthesise prot may be a property which living material only acqui at a late stage of its evolution, and that prope may be one which in the process of time has come be essential for the maintenance of the comp structure of the nucleus as we see it to-day.

DIABETES AS A PHYSIOLOGICAL PROBLEM.*

BY J. J. R. MACLEOD, M.B., LL.D. ABERD F.R.C.P. LOND., D.SC. (HON.) TORONTO, F.R.S. REGIUS PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF ABERDEEN.

LECTURE II.

Regulation of the Secretion of Insulin.

THE internal secretion of insulin must be adjus from time to time according to the needs of organism, and it is probably safe to assume tha greater secretion will be required when preform carbohydrates, rather than protein and fat, are foodstuffs being assimilated. When glands such the salivary become active, definite histolog changes can readily be observed in the cells, such the extrusion into the ductules of the zymo granules which are believed to form the precur of the active constituents of the secretion. In ductless glands, owing to the difficulty of exci them to short bouts of greater activity, sim histological changes are not so readily demonstra Under certain conditions the isles of Langerh as Homans,[84] F. M. Allen,[25] and Bowie[26] h shown, show peculiar changes affecting the gran of the so-called β-cells. These conditions fulfilled by extirpation of all the pancreas exce small graft, which may be transplanted into abdominal wall without disturbing its blood- or ne supply. Because of the removal of most of the i tissue, a great strain is put upon the remai grafted portion to secrete sufficient insulin, an food rich in carbohydrates be given, this st ultimately tells on the islets, so that peculiar cha become visible in their cells, involving a hydr degeneration of the protoplasm. There can

*The Oliver-Sharpey Lectures delivered before the R College of Physicians of London on April 29th and Ma Lecture I. appeared in THE LANCET of August 23rd.

little doubt that this change is related to the insulin-secretory function of the cells, because it does not occur when the animals are treated with insulin and is much less marked if the diet does not include preformed carbohydrate. Moreover, if insulin be given to an animal in which hydropic degeneration has already started—as revealed by examination of a small portion of tissue removed from the graft—this may disappear and the cells revert to their normal condition (Allen, Bowie, loc. cit.).

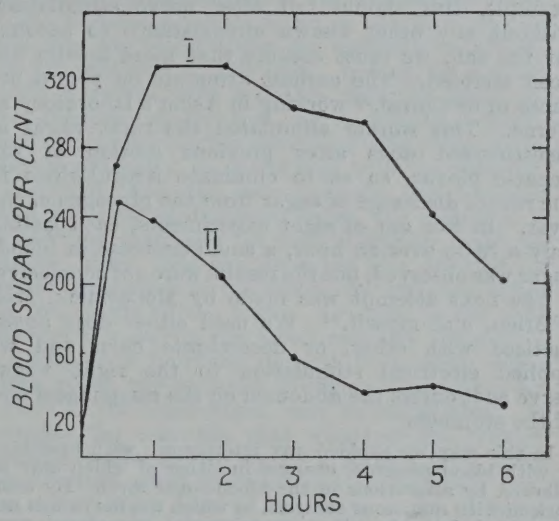
EVIDENCE THAT THE SECRETION OF INSULIN VARIES FROM TIME TO TIME.

Measurement of the changes that occur in the amount of insulin in the blood and tissues cannot be made by methods of extraction, because these are not sufficiently thorough or standardised to be carried out accurately, especially in material such as blood which contains at most only traces of insulin. The available methods for observing changes in the discharge of insulin into the venous blood of the pancreas are indirect. It is a well-established fact that the hyperglycæmia which follows upon the ingestion of sugar is much more marked in laboratory animals (rabbits) which have been deprived of food for some days previously than in recently fed ones (Bang [27]). This is well shown in the curves (Fig. 3) of experiments by Tiitso.[28] After several injections of sugar into starved animals, the hyperglycæmic response also becomes less. Similar results have also been obtained on man, especially by Staub [29] and Traugott,[30] and, as has also been shown by Thalheimer,[31] when successive small amounts of glucose are given by mouth (in man), the blood-sugar, although at first rising after each portion, finally fails to respond. If these results depend on the fact that the internal secretion of insulin is regulated by the amount of carbohydrate entering into metabolism as such, it should be possible to demonstrate that differences in the effects of insulin are dependent upon the state of the carbohydrate metabolism at the time of its injection. This has been found to be the case. For example, insulin causes the blood-sugar to fall more markedly in anmals (rats, rabbits) which up to the time when food was withdrawn before injecting them with insulin, have been kept on carbohydrate-rich food, than in animals which have been deprived of food for several days or have been on a diet poor in carbohydrate (Abderhalden and Wertheimer,[32] Tiitso [33]). Then, again, Staub [34] has made the interesting observation that transfusion into a diabetic patient of 400–500 c.cm. of blood from a healthy person who some time previously had partaken of a meal rich in carbohydrate caused the blood-sugar to fall as if insulin had been injected. When the donor had fasted for 24 hours the transfusion did not affect the blood-sugar level of the diabetic.

There are numerous other characteristics of the effects of insulin which can be adequately explained in terms of the above hypothesis. Thus, following the hyperglycæmia caused by the ingestion of sugar, the blood-sugar falls below the level at which it stood before the sugar was ingested (Folin and Berglund [35]), owing, no doubt, to the fact that the islets become stimulated by the increased concentration of sugar in the blood. There are reasons for believing that this stimulus is more effective when the sugar is absorbed from the alimentary canal than when it is given extraparentally; at least, Eadie, [36] Tiitso, [37] and [38] were never able to observe that the blood-sugar in rabbits fell below its normal level after the hyperglycæmia caused by the intravenous or subcutaneous injection of glucose. Koref and Rigler [39] also state that the blood-sugar ultimately sinks lower in rabbits when they are injected intravenously with insulin and glucose than with the same amount of insulin alone, and corresponding results have been obtained on healthy human subjects by Depisch and Hasenöhrl.[40]

The paradoxical result is, therefore, obtained that following small doses of insulin *plus* glucose a more marked degree of hypoglycæmia becomes developed than after the same amount of insulin alone. Of course, in the former case a temporary rise in blood-sugar precedes the development of hypoglycæmia.

FIG. 3.



I. Blood-sugar curve after administration of 3 g. glucose per kg. body-weight subcutaneously in starved rabbits. Average of nine experiments. II. The same in fed rabbits. Average of ten experiments.

In all the above cases we may imagine that when there is abundance of preformed carbohydrate (free sugar and glycogen) entering the metabolism, the islets of Langerhans are stimulated to produce larger amounts of insulin than usual, and to secrete it more abundantly, in response to temporary increases in the blood-sugar.

NERVE CONTROL OF THE ISLETS.

Granted that increase in blood-sugar stimulates the islets, the question arises as to the mechanism by which it does so. We have here two distinct and separate problems: (1) does the stimulus depend on the increased sugar concentration itself, or on some related substance or on some hormone the internal secretion of which depends on the sugar? and (2), does the stimulus act directly on the islet cells or indirectly through the nervous system? In the latter case we have also to remember that the locus of action might be either the nerve centre from which the insular fibres arise or some afferent receptors acting on this centre. Let us in the first place consider the possibility of direct nerve control. In attacking such a problem, the first question that arises is the anatomical one: do nerve-fibres run directly to the insular cells, and, if so, in which nerve trunk are they carried? An apparently conclusive answer to this question has been given by various histologists. Thus, it has long been known that a rich plexus of myelinated nerve-fibres surrounds each islet, and it has been demonstrated that fine branches from this plexus invade the islets and lie between the columns of cells of which they are composed (Gentes, Pensa).[41]

Non-myelinated fibres have also been described by de Castro as penetrating the islet cells. The peri-insular plexus has been shown to be connected with branches of the right vagus nerve (McCrea and de Castro).[42]

With these facts as an anatomical basis, various attempts have been made to demonstrate that the secretion of insulin is controlled by the vagus nerve. As we have seen, there is no direct chemical method for the accurate measurement of the concentration of insulin in blood, and there is only one indirect method by which the rate of its internal secretion can be approximately gauged, that is, by observing the behaviour of the percentage of blood-sugar. If, for example, this should fall after nerve stimulation, without any other known circumstance to account for the fall, we must assume that more insulin has been secreted. The earliest attempts on record are those of de Corral,[43] working in Asher's laboratory at Berne. This worker stimulated the right vagus in anæsthetised dogs after previous section of the hepatic plexus, so as to eliminate irregularities in the rate of discharge of sugar from the glycogen of the liver. In five out of eight experiments, each lasting only a little over an hour, a small decrease in blood-sugar was observed, but the results were not conclusive.

The next attempt was made by McCormick, Miss O'Brien, and myself.[44] We used either dogs anæsthetised with ether, or decerebrate cats, and we applied electrical stimulation to the right vagus nerve as it enters the abdomen on the œsophageal end of the stomach.

In this way we avoided any interference with breathing or with blood pressure, changes in either of which may be followed by alterations in the blood-sugar level. By comparison with numerous controls, in which the nerve was not stimulated but the other experimental procedures were carried out, we succeeded very definitely in one experiment in demonstrating a prompt fall in blood-sugar during stimulation of the nerve and a more gradual return to normal when it was discontinued. In four other experiments the fall was less decided, and when the stimulation was maintained the blood-sugar either remained depressed, with some irregularities, or returned towards the normal level.

Although we did not consider these experiments as final proof that the secretion of insulin is subject to nerve control through the right vagus, there can be no doubt that they point strongly in this direction.

The problem was then taken up by Britton [45] who, using cats under barbituric acid anæsthesia, stimulated the right vagus on the œsophageal end of the stomach after cutting the branches going to this organ and to the upper intestine. As a rule, the hepatic plexus of nerves was also cut, in order to eliminate the possibility of nervous stimulation of glycogenolysis in the liver, and the left adrenal gland was removed, or its nerve-supply cut, to prevent any possible hypersecretion of epinephrine. Either of these occurrences, by causing hyperglycæmia, might mask any hypoglycæmic effect of vagus stimulation. These operations were performed several hours before the actual experiment, so that their possible disturbing effects on the blood-sugar level might have passed off. In a typical case it was found that immediately after cutting the vagus the blood-sugar rose somewhat and that it fell considerably during stimulation. This was maintained for one to three hours in the various experiments, and after removal of the stimulation the blood-sugar rose again.

The average decrease in the percentage of blood-sugar in a series of 11 experiments in which the hepatic nerves were cut was 18 mg. per hour, and in another series of 6 experiments in which they were intact it was 27 mg. The fall was greater when the level of blood-sugar was high to start with than when it was low, which is also the case when insulin is injected. Further controls were instituted to ensure, first, that the liver contained sufficient glycogen to maintain the blood-sugar level in the absence of nerve stimulation, and, secondly, that dilatation occurring in the pancreatic blood-vessels as a result of the stimulation was not in itself responsible for the hypoglycæmia by causing a more complete removal from the islets of insulin discharged at a constant rate from them. Finally, experiments were performed in which the blood-vessels and nerves of the pancreas were tied before stimulation of the vagus, which then did not affect the blood-sugar level.

The investigation was, therefore, a well-controlled one and the results show decisively that the right vagus nerve contains insulin secretory fibres. They indicate also that these have a tonic influence on the secretion. But although the presence of secretory fibres can be demonstrated under experimental conditions in which the blood-sugar is at a fairly high level before the nerve is stimulated (as in Britton's experiments), this does not necessarily mean that the islets are subject to nerve control when the blood sugar is normal. A similar question arises in connexion with the nervous control of breathing; afferent expiratory fibres can be demonstrated in the vagus nerve under experimental conditions, but it is almost certain that these are not concerned in normal quiet breathing. Impulses to the islets through the vagus nerve may only come into play when control in other ways, such as by hormones, is inadequate to keep the blood-sugar at the normal level, or as an emergency measure.

Further investigation of the problem has, therefore, been undertaken by La Barre and his various collaborators, who have employed the methods of cross circulation between two animals which were first used in 1913 by E. Hédon [46] for demonstration of the presence of insulin in the blood. Hédon transfused the carotid blood of a normal animal into one that was depancreatised and found that this caused a decided, although not a marked, lowering of blood sugar. By anastomosing the vein coming from the head of the pancreas of a large dog with the jugular vein of a small one (both animals being under chloralose anæsthesia), La Barre [47] obtained more striking results, no doubt because there was no dilution of the pancreatic blood by that of the rest of the body. He allowed the blood to transfuse into the smaller animal for periods of half to one hour, until its weight had increased by 100–140 g. When both animals were normal this did not cause any change in the blood-sugar level.

In a further series of observations the thorax of the donor animal was opened under artificial respiration and electrodes were placed on the right vagus nerve after it had been cut below the cardiac branches. Both adrenal glands were also removed, so as to eliminate the possibility of an increased secretion of epinephrine which might mask the effects of insulin. While the pancreatic blood of the animal was being transfused into another one its vagus nerve was stimulated electrically for a period of 15–20 minutes; after separating the animals the blood-sugar of the recipient was found to fall from about 0·115 per cent. to about 0·075 per cent.

So far the results merely corroborate those of ourselves and of Britton, in demonstrating that stimulation of the vagus may cause hypoglycæmia, but the further researches add others of far greater importance since they show that this nerve control is stimulated by an increase in the blood-sugar.

Thus, La Barre found that the intravenous injection of glucose into the donor animal caused the blood-sugar of a previously adrenalectomised recipient to fall by about one-third and to remain at this level for three or four hours although the transfusion of blood only lasted for half an hour. This maintained hypoglycæmia is supposed to have been due to the absence of any compensatory hyperglycæmic effect of epinephrine secretion in the recipient. The result seems clearly to indicate that excess of sugar in the systemic blood increases the insulin concentration

e pancreatic blood, and in the next series of experiments was shown that this depends on excitation of the islets rough the vagus nerves. Thus, it was found that when ese nerves were cut in the thorax of the donor or were ropinised, the injection of sugar did not lower the blood-gar of the recipient (adrenalectomised) dog.

Under the same experimental conditions injection of inephrin into the donor also caused hypoglycæmia in the cipient, but in this case previous vagotomy did not olish the hypoglycæmic effect in the donor (Zunz and Barre), indicating that epinephrine has a direct stimula-ng action on the islets. When insulin hypoglycæmia is induced in a donor upon which adrenalectomy had en performed, transfusion of its blood into a depan-eatised dog did not lower the blood-sugar level. This sult shows that the secretion of insulin is suppressed by poglycæmia, since, as we have seen, the pancreatic vein ood of a normal animal lowers the blood-sugar of a pancreatised recipient.

That it is on the centre of the vagus and not on efferent pathway that the hyperglycæmic blood ts was shown by an experiment in which three gs were used.

Between two of them (A and B) a double carotid jugular astomosis was established and the remaining blood-ssels in the neck of B were ligatured. In this way the ain of B was perfused by the blood of A. The vagus rves of B were left intact and the body of the animal s kept alive by artificial respiration. The pancreatic n of B was then anastomosed with the jugular of the third g, C, and it was found that injection of glucose into A used the blood-sugar of C to fall and to continue depressed several hours after the animal was separated from B.

The results of these amazing experiments would ppear to demonstrate beyond all doubt that the secretory activity of the islets is under control of the agus centre, and that this is stimulated by an increased concentration of glucose in the blood. This erve-control is of importance in connexion with glycogen formation in the muscles. Thus, after glycogen has been removed from the muscles of a nal cat by stimulating them, it will not reap-ear unless excess of insulin is injected. On the other nd, it will reappear in an anæsthetised cat with ain intact without injecting insulin, but will fail to o so if the vagus nerves are cut (especially the left de), or if the pancreas is removed (Debois and bet [48]).

The exact relationship of the vagus to the secretion of insulin is, however, not yet quite clear. G. A. Clark,[49] for example, has adduced evidence to show that, as well as exciting, this nerve may inhibit the secretion of insulin. He found in rabbits that drugs which stimulate the parasympathetic system cause lowering of blood-sugar, but usually fail to do so after section of the right vagus. Clark points out, however, that vagal control of insulin secretion can only come into play under certain circumstances and cannot be essential for maintaining the blood-sugar level, at least in animals leading a placid life in confinement. Thus, shortly after section of the right vagus below the cardiac branches in rabbits the blood-sugar fell immediately, and there was no vification of decreased tolerance following the intra-venous injection of glucose (1 g. per kg.). On the contrary, the blood-sugar curve returned more rapidly to normal, thus suggesting that the injected sugar was being better dealt with than it had been in the same animal before vagotomy. After a period of two months, however, the condition became reversed and the hyperglycæmia following the injec-tion of glucose lasted decidedly longer than usual. The insulin-regulatory fibres in the right vagus would appear from these results to be of two kinds, both inhibitory and secretory; but even if we adopt this hypothesis to explain Clark's results we are left with the problem, why the tolerance for sugar should be actually depressed in two months after the vago-tomy (Clark).[50] It may seem strange that through the self-same nerve there should come to the islets impulses which may either stimulate or inhibit the internal secretion of insulin, but it must be remembered that much the same state of affairs exists in the afferent impulses to the respiratory centre. In view of the results of these various experiments there can be little doubt that the vagus centre exercises some sort of control over the internal secretion of insulin, but it is difficult to estimate its physiological significance.

HORMONE CONTROL OF THE ISLETS.

That nerve control comes into play under certain experimental conditions does not necessarily mean that the variations which occur in the discharge of insulin into the blood under the ordinary conditions of life are regulated in this way. Indeed, on a priori grounds it seems more probable that the islets are under chemical rather than nerve control. Nerve control of glands is highly developed when these have to secrete promptly, as is the case with the salivary, the lacrymal, and the sweat glands, but hormone control becomes predominant when the secretion is only required gradually, as that of insulin must be. Assuming, then, that the islets are also affected by chemical substances in the blood, the question arises as to the nature of the latter. Changes in the concentration of sugar in the blood may act directly on the islets, or a hormone derived from some other ductless gland, the secretion of which is regulated by the state of the blood-sugar, may be responsible. It is possible, for example, that whenever the tension of glucose tends to rise above a certain level some other ductless gland is stimulated to secrete a hormone, which then acts on the islets so as to bring about the secretion of insulin. Speculative hypotheses of this type have from time to time been freely put forward in connexion with carbohydrate metabolism, but there has been little direct evidence to support them, no more indeed than the fact that changes in the blood-sugar level, or in the tolerance for carbohydrate, can be brought about by removing some gland, or by injecting extracts of it. When we bear in mind the extreme complexity of the factors which control carbohydrate metabolism it is evident that such hypotheses are of little value and can serve to stimulate further inquiry provided only that they are based on some firmly established facts.

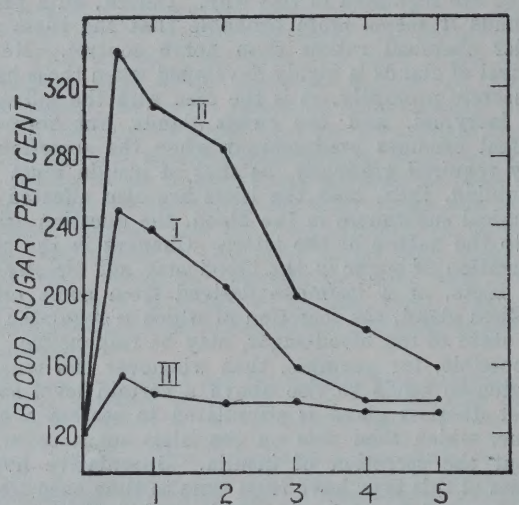
Are there, then, any facts which show that other hormones than insulin have an influence on carbohydrate metabolism and, if so, do they act directly on the various mechanisms concerned in the production or utilisation of sugar, or indirectly by influencing the secretion of insulin from the islets? I will take by way of example the results which have been obtained by various investigators who have experimented with the thyroid gland.

It has been known for some time that the assimilation limit for sugar is significantly altered by thyroidectomy, or by feeding with thyroid (Cramer and Krause,[51] Kuriyama [52]), and that the susceptibility of sheep towards insulin can be made to change by similar treatment (Bodansky [53]). But the results which I wish more particularly to discuss are those obtained by Burn and Marks,[54] who showed that after thyroid gland had been daily added to the food of rabbits for about a week the animals became relatively insensitive towards insulin, so that hypoglycæmic symptoms did not supervene even when they were injected with ten times the usual convulsive dose. At this stage it was also found that the injection of epinephrine resulted in a much greater increase in blood-sugar than usual. These results could most simply be explained as being due to a rapid breakdown of hepatic glycogen, but since this substance was found by actual analysis to be unchanged in amount, it was concluded that its stability had become diminished, so that it was more readily discharged as sugar

into the blood in response to the stimulus, either of a lowered blood-sugar level or of the presence of excess of epinephrine.

After the thyroid feeding had been kept up for two or three weeks, a complete reversal occurred in the response of the animals to insulin and epinephrine; they became hypersensitive to the former and irresponsive to the latter hormone. Confirmatory results were obtained by comparing the extent to which administration of sugar produced hyperglycæmia at various stages of thyroid feeding. For example, in the curves of Fig. 4, which are taken from the work by Tiitso in my laboratory and in which the extent of the rise in blood-sugar is compared in normal rabbits (I.), with that occurring in the same animals after feeding for a week (II.), and for longer periods (III.), with thyroid, there is at first an increase and then a marked decrease in the hyperglycæmic response to sugar. After prolonged thyroid feeding, therefore, the animal becomes extremely sensitive towards insulin injections, whereas epinephrine can scarcely

FIG. 4.



I. Blood-sugar curve following subcutaneous injection in normally fed rabbits. II. The same in rabbits fed for five to six days with thyroid. III. The same in rabbits fed for more than ten days with thyroid.

cause hyperglycæmia, and administration of sugar either fails to affect the blood-sugar level—as in Tiitso's observations—or, as Marks has shown, may actually cause the blood-sugar, after a slight preliminary rise, to fall to the level at which fatal hypoglycæmic symptoms supervene.

How are these results to be explained? The prolonged thyroid feeding is associated with a practical disappearance of glycogen from the liver, but, although this might in itself be considered as adequate to explain the results with insulin and epinephrine, it fails to account for the intense hypoglycæmia which follows sugar administration. There is some probability that Marks's explanation is the correct one—namely, that the administration of sugar causes increased secretion of insulin from the islets. Prolonged administration of thyroid seems, therefore, to bring about two definite changes in carbohydrate metabolism: it renders the liver incapable of forming—or at least of storing—glycogen, and at the same time it greatly sensitises the secretion of insulin. The upset of the glycogenic function is undoubtedly secondary to the excessive secretion of insulin, for, although both Goldblatt [55] and Sahyun and Luck [56] have shown that glycogen accumulates in the liver at early stages after the injection of this hormone in young rabbits, there is abundant evidence to show that its effect is to depress it in other animals.

I have chosen these results as offering the best evidence I know in support of the view that the secretory function of the islets is subject to control by hormones derived from other glands, but ev they are not entirely convincing, for we have to be in mind that thyroxin also has a profound effect metabolism in general. Its calorigenic effect, example, indicates that it alters the metabolic r of the tissues, and it is permissible to suppose th the influence which it has on alimentary hyp glycæmia is dependent upon its causing over-stimu tion of the assimilatory powers of the tissues. W can see, therefore, that the answer to our m question, whether changes in the glucose concent tion of the blood affects the islets directly or directly—either through hormones from other gla or by nervous control—cannot as yet be expected be a final one.

Ætiological Factors Involved in Human Diabetes.

In the light of these experimental results, it m be of interest to examine in a general way the æt logical factors which are believed to be involved human diabetes. Disregarding entirely the inher tendency to the disease and its possible occurrence a result of luetic or other infective lesions involv the islets, it may be stated that there are th conditions which seem clearly to lead to its devel ment—over-eating, obesity, and nerve strain. seems to be accepted by physicians that intempera in eating, especially when coupled with sedent habits, is decidedly predisposing to diabetes, an it is at least possible that this may depend on a c tinued overstraining of the islets. We can imag that the continued call for insulin when carbohydr metabolism is working under high pressure leads a breakdown of the overworked insular cells, a v which has been supported by F. M. Allen's exp ments on partially depancreatised dogs. Gran then, that intemperance in diet may lead to a bre down in the insulin-producing function of the isl the question arises whether the over-stimulation their cells occurs through their nerve control through direct action of some hormone on them. appears to me to be most unlikely that the for could be the mechanism involved, since no condi is known in which persistent over-stimulation nerve-supply brings about degeneration or atro of the organ or tissue concerned. It is much m likely that a humoral mechanism is involved. the other hand, it seems that it must be throug breakdown of the nerve control that the islets c to function inadequately in those cases in which incidence of diabetes is related to conditions of n strain. But it will require much further analysi this relationship to make it certain that these p posed nervous cases do not really belong to dietetic group. An analysis in this direction by Jo has made it at least not impossible that most of cases in which the chief ætiological factor has appe to be a nervous one can be shown to have bee patients who were assimilating food beyond t metabolic requirements.

Methods for Detecting Changes in Insul Secretion in Man.

Intimate association between the experiment and the clinician has been a feature of researc carbohydrate metabolism. Much of the informa revealed by experiments on animals has been invaluable guide in the control of diabetes in and, on the other hand, careful observation of disease by the clinician has frequently indicate the experimentalist the pathway along which should proceed in searching further for the natu

ıe metabolic fault which causes it. Without the utual coöperation of the two groups, it is certain ıat we should not now be in possession of a means y which the diabetic can be relieved of all his mptoms, so that he can follow his usual pursuits ith but little, if any, handicap.

One of the most interesting of the problems which e on the border-line between laboratory and clinic ncerns the control of the secretion of insulin in an; whether this undergoes alterations under rmal conditions and whether such alterations, if ey occur, have any relation to the onset of diabetes. he symptoms by which an increased internal secre-on of insulin may be recognised in man are: (1) tual hypoglycæmia while in the basal state; (2) an cessive fall below the normal level of blood-sugar llowing post-prandial hyperglycæmia; and (3) an cessive difference between the sugar percentages in pillary and venous blood. Spontaneous (idio-thic) hypoglycæmia in man may be suspected hen the basal blood-sugar is found to be lower than 08 per cent. Sometimes it may fall well below the ual convulsive level without the development of y definite symptoms, cases having been reported children in which the percentage of blood-sugar as only 0·038 without anything abnormal being served in their behaviour (Talbot, Shaw, and oriarty [57]). Even when hypoglycæmia is present cannot be regarded as a certain sign of hyper-sulinism, since the blood-sugar may fall far below s usual level in perfectly normal conditions, as after renuous and prolonged muscular exercise. Here e rapid utilisation of the glycogen of the muscles ust be regarded as the primary cause of the hypo-ycæmia, and it is of interest that the ingestion of gar usually gives prompt relief to many of the bjective symptoms of fatigue. The blood-sugar ay also fall to an unusually low level when milk is ing actively secreted both in the depancreatised g and in the milch cow, but Harding and Downs [58] ny that it becomes subnormal in nursing women. ith these reservations, however, we are probably rrect in regarding as indicative of hyperinsulinæmia y condition in which the basal blood-sugar is rsistently below the limits which I have indicated.

It is possible that the second and third methods to hich I have referred are capable of detecting altera-ons in the secretion of insulin in man that would not preciably affect the basal blood-sugar level, and episch and Hasenöhrl [59] have paid attention to this roblem. They consider that the blood-sugar should t fall by more than 20 per cent. below the normal vel after the hyperglycæmia caused by 100 g. of ucose, and that the differences between the percen-ges of sugar in venous and capillary blood in about e hour after beginning to drink the sugar solution 0 per cent. taken slowly during half an hour) should t exceed about 15 per cent. The principles upon hich these methods depend have been established the work of numerous investigators, both experi-ental and clinical, more especially by Frank, othmann, and Wagner.[60] It is claimed for them at they tell us directly whether or not insulin is esent in proper amount, and not merely whether e abnormal reaction to sugar depends on a balanced fect of insulin and other hormones acting on the ycogenic function of the liver. According to episch and Hasenöhrl, deviations from the normal" difference can be detected in non-abetic persons in whom there is a tendency obesity or to excessive leanness. In diabetes elf the difference disappears. It will take con-derable investigation to ascertain whether these methods are really any more dependable than that of the sugar assimilation curve for detecting early stages of diabetes or other pathological disturbances of carbohydrate metabolism.

Hyperinsulinism.

What more particularly interests us is a consideration of the cases in which hyperinsulinism becomes of clinical significance. Although earlier cases have been reported that of Wilder, Allan, Power, and Robertson [61] is the most complete.

Their patient was a surgeon, aged 40, who, in November, 1925, after an unusually long day in the operation theatre, was overtaken by weariness, confusion, and ultimately by collapse, these symptoms being promptly removed by taking an egg-nog. Attributing his condition to hyperinsulinism, the patient found that he could ward off attacks by taking food at frequent intervals. As time passed the tendency to hypoglycæmic symptoms increased and it became necessary for his wife to watch for signs of unusual behaviour while he was asleep, and to give him sugar for their relief. Some time before the onset of these symptoms those of gastric distress and of renal colic had been experienced, and at one time mild diabetes had been diagnosed. In October, 1926, when the patient came under the care of Wilder and his associates, it was found that the symptoms manifested themselves in a little over three hours after the noon-day meal, when the blood-sugar was 0·055 per cent. In four hours they became pronounced, and included perspiration, muscular twitching, and incoherence of speech. The blood-sugar at this stage was 0·036 per cent., and 15 minutes later, when it was 0·027 per cent., the development of stupor and convulsive jerkings made it necessary to give sugar, with the result that in ten minutes recovery was well established. From among the other clinical data, the following are of significance: 1. Administration of either epinephrin or pituitrin did not affect the hypoglycæmic symptoms or delay the fall in blood-sugar. 2. When sugar solution was continuously delivered into the duodenum through a tube, from 20 to 25 g. an hour were required to ward off the symptoms.

On Dec. 4th an abdominal operation revealed a cystic tumour in the tail of the pancreas and a hard nodular one in the right lobe of the liver. A small portion of the normal liver substance was removed and found to contain 3·49 per cent. of glycogen. This is of great physiological importance, since it indicates that the failure of epinephrin to combat the symptoms was not due to an insufficiency of hepatic glycogen, from which this hormone might produce sugar. The post-operative management of the case was difficult and demanded the continuous intravenous injection of glucose for 63 hours, when the nausea disappeared and glucose could be given by mouth. The condition became worse after the operation, so that the daily glucose value of food (sugar *plus* other food) had to be increased to 1000 g. to ward off the hypoglycæmic symptoms. The patient died one month after the operation.

Examination of the tumours removed, within three hours after death, from the pancreas and the liver showed the former to consist of focal masses of tumour cells embedded in a dense connective tissue stroma and arranged in irregular strands and islands. The cells had a striking resemblance to those of the isles of Langerhans, and here and there some of them were degenerating. But the most significant observation was that the neoplasm in the liver was also composed of similar cells. It was identified as a carcinomatous metastasis arising from the island cells, and an extract made from this metastasis showed it to contain a relatively large amount of insulin. Neighbouring portions of healthy liver similarly extracted were found to contain no insulin, but to be loaded with glycogen (8·25 per cent.).

This excellently described case establishes the existence of a hitherto unknown disease, and since its publication others have been described by McClenahan and Morris,[62] by Thalheimer and Murphy,[63] by F. N. Allan,[64] and by Howland, Campbell, Maltby, and Robinson.[65] These are important because they carry us a step further in showing that the hypoglycæmic symptoms may be cured by surgical operation.

Allan's patient, a farmer 52 years of age, had suffered frequently, for about two years before he came under observation, from attacks of weakness and stupor which could at first be warded off by taking food at short intervals. At the time the patient came under observation the blood-

sugar while fasting fell to 0·04 per cent., at which level the usual hypoglycæmic symptoms supervened and, since these could no longer be satisfactorily controlled by taking food, it was decided to operate. No tumour being found in the pancreas, a portion (14 g.) was removed so as to restrict the production of insulin. This apparently resulted, since the hypoglycæmic attacks became much less frequent, three meals a day being as a rule adequate to prevent them.

The case described by Howland et al was a woman, aged 52, in whom convulsions and coma, along with mental symptoms and excessive sweating, had been frequent for six years before admission to hospital. Hypoglycæmia was found, but the most remarkable feature of the case was the erratic response to carbohydrate administration (dysinsulinism). Thus, intravenous injection of glucose solution would remove the coma only temporarily, whereas, when sugar was given by mouth, recovery was satisfactorily maintained and the blood-sugar rose to diabetic levels. Operation was decided upon, and a pancreatic tumour was found, which proved to be a slowly growing carcinoma. It was removed, with the result that the patient—during the 14 weeks which the record covers—remained free from her previous symptoms.

These case-histories are invaluable ready-made experiments, which demonstrate that the islet tissue may proliferate and become hyperactive during adult life. In Allan's case the proliferation was unaccompanied by tumour formation, and this would seem to me to indicate the possibility that excessive variations in insular activity may sometimes be a cause of vague metabolic disturbances in man, particularly of those in which either abnormal corpulence or leanness is the chief symptom. Various clinical observers have had this possibility in mind (cf. Falta [66]), and I would venture to suggest that it should continue to be examined by such methods as I have outlined.

That the islet tissue may vary in amount from time to time opens the question of its derivation, and it is interesting to recall the oft-repeated conclusion of Laguesse [67] that the duct epithelium is not the only structure from which insular cells may be derived, but that the acinar cells may also become transformed into them.

Hypoglycæmia in Diabetes.

The hypoglycæmia we have just been considering differs essentially from that which is not uncommonly met with in diabetic patients. The main cause of the greater susceptibility of the diabetic to insulin is inadequate storage of glycogen in the liver, for although this substance may continue to be formed out of protein and fat, it cannot be stored up sufficiently in the liver to meet the extra demands of the organism for sugar (cf. Joslin [12]) occasioned either by excess of insulin or by increased muscular activity. Muscular fatigue is therefore to be avoided in diabetic patients, although graded exercise is beneficial in that it reduces the requirements for insulin (cf. Gerl and Hofmann [68]). When the demands of the organism for sugar become excessive, as after sustained muscular effort, hypoglycæmia of sufficient degree to cause marked symptoms may supervene even in perfectly normal persons (marathon runners) and the symptoms can be immediately relieved by the ingestion of sugar (Levine, Gordon, and Derick [69]). In epilepsy in children and in progressive muscular dystrophy hypoglycæmia is also said to occur.

Substitutes for Insulin.

The activity of the islets can probably be stimulated by various drugs acting on them either directly or through the nervous system. From a therapeutic standpoint this is of very great importance, since it is obvious that relief could in this way be obtained from the diabetic symptoms but at the risk of causing a further deterioration of the secretory powers of the already overtaxed islet tissue. Among the substances which may act in this way, synthalin, myrtillin, and bile-salts deserve some attention, the first two more especially as having been recommended as substitutes for insulin in the treatment of diabetes. Since whatever effects they may have are manifested when they are given by mouth, much attention has been devoted to seeing whether they really possess any clinical value and might therefore be used in cases in which hypodermic medication is undesirable.

Synthalin is a compound containing two molecules of guanidin along with ten or more of methylene (dodekamethylendiguanidin). It was introduced by Frank, Nothmann, and Wagner,[70] who showed that although guanidin itself lowers the blood-sugar in rabbits, as had previously been known, it does not significantly do so in depancreatised dogs, whereas synthalin acts on both. The hypoglycæmia which synthalin produces is often preceded by hyperglycæmia, this depending on dosage, and also—according to Bodo and Marks [71]—on the glycogen content of the liver. These workers also found that synthalin lowers the sugar in the fluid perfused through the isolated muscles of the leg (in dogs), and raises the respiratory quotient of eviscerated spinal cats. But these results may not be of much significance since lactic acid also accumulates in the blood. Synthalin inhibits the deposition of glycogen in the liver of rabbits after ingestion of sugar (Rubino, Varela, and Collazo [72]) and causes damage to the liver cells, especially on repeated administration (Hornung [73]), Fuentes,[74] Simola [75]). Although Frank, Nothmann, and Wagner [76] state that synthalin in its latest form and in suitable dosage is effective in lowering the blood-sugar and in alleviating the other symptoms of diabetes in depancreatised dogs without causing any liver damage, this has not been the experience of others (Rathery, Kowiilsky, and Gibert [77]) and it therefore signifies but little that the drug may temporarily revive fasting phlorhidzinised dogs that are comatose from acidosis. If it has any effect in diminishing the diabetic symptoms in phlorhidzin poisoning, this can easily be attributed to its stimulating action on the internal secretion of insulin. In face of all these experimental results it is not surprising that synthalin should have proved to be a unsuitable, if not indeed a dangerous, drug to use in the treatment of diabetes in man (Graham and Linder,[78] and Joslin [79]).

It is possible, as Bischoff, Sahyun, and Long [80] have shown, that guanidin compounds having insulin-like effects on normal animals even more pronounced than those of neosynthalin may be discovered, but I do not consider that any of them should be used in the treatment of diabetes in man until it is definitely established, not only that they can remove all the symptoms of this disease in completely depancreatised dogs, but also that they can keep the animals in perfect health for a period which is, at least, much longer than that which Soskin has shown is possible in the case of untreated animals.

What I have said of synthalin applies also to myrtillin, although this drug has the advantage that it does not apparently have a toxic action on the liver. It is, at least, harmless. Myrtillin was prepared by F. M. Allen [81] from the leaves of plants of the myrtle family, it being believed among the Alpine peasantry that infusions of these leaves have antidiabetic properties. Myrtillin has been said to relieve the symptoms of diabetes in partially depancreatised dogs and to prolong their lives, but it has no effect on the blood-sugar level in normal animals nor does it in the slightest degree influence the

mptoms or the course of the diabetes in completely pancreatised dogs, as was shown in my laboratory Toronto by Drs. Chaikoff and Soskin. In the light these laboratory findings I can see no justification r attempting to use myrtillin in the treatment of abetes in man.

The results of bile-salts are not very striking. orsters [82] has shown that 1 g. orally, or 0·5 g. travenously (especially denoxycholalic acid), after ithholding food for 24 hours, may lower the blood-gar in rabbits to about 50 per cent. of the normal. milar results were obtained in dogs, in which the imulating effects of these salts on the pancreatic cretion were also readily demonstrable. On the her hand, no hypoglycæmic effects were obtained y giving bile-salts to diabetic (depancreatised) dogs, that their action is clearly dependent upon stimu-tion of the secretion of insulin by the islets. It is ggestive that both the internal and the external cretions of the pancreas should be stimulated in is way, and there is some evidence that the pan-eatic secretion in man is increased after insulin jections.[83]

The researches which I have just reviewed do not courage the hope that some substitute for insulin, pable of acting by the parenteral pathway, will be scovered, nor does it appear likely that any means ill be found by which insulin itself can be made to splay its action by other methods of administration an injection subcutaneously or intravenously. urlin and Hawley,[84] and Miller,[85] have given much tention to the possibility that the ingestion, either very large amounts of insulin itself or of insulin ssolved in alcohol and contained in keratinised psules, might be efficacious, but the results are not fficiently positive to justify the risk of attempting ch methods in the clinical treatment of diabetes. he difficulty is, of course, that insulin is rapidly stroyed by the digestive ferments. This suggests s close relationship to protein, and it is significant at crystalline insulin, as prepared by Abel [86] and s pupils and by Harington and Scott,[87] possesses any of the characteristics of protein. By hydro-sis of crystalline insulin various amino-acids have en isolated (arginine, histidine, and leucine) and lphur is present in relatively loose combination, t it is not yet certain whether the antidiabetic roperties are dependent upon the molecule as a hole or on some side group—for example, that in hich the sulphur is contained. It is at least signi-cant in this connexion that four different samples crystalline insulin, two of them prepared by Abel's ethod and two by that of Harington and Scott, ould have been found to possess practically the me strength, 23·3 units per mg., when assayed—by mparison with the international standard prepara-on—on both rabbits and mice. Since this value is so reached by the best commercial preparations of sulin, which are amorphous, it does not appear that ystalline preparations do much to reveal the nature insulin. Insulin appears to be as intangible as tamins and enzymes; like these, its activities may epend on some little-understood molecular grouping hich, by contact rather than by actual combination, nders the glucose molecule unstable so that it can ore readily be utilised in metabolism. Carr, Culhane, uller, and Underhill [88] recently obtained significant sults showing that insulin can be completely activated by treatment with ethyl alcohol and ydrochloric acid; the reaction is a reversible one, nce the original potency can be completely restored y treatment with dilute sodium hydroxide. It is ggested that the change undergone by insulin by this treatment is an esterification but, whatever may be its nature, the fact that reversible inactivation occurs opens up interesting possibilities with regard to the behaviour of insulin in the body.

LUNG PUNCTURE IN ACUTE LOBAR PNEUMONIA.

By Donald Stewart, M.D., M.R.C.P. Edin.,

ASSISTANT PHYSICIAN, LEITH HOSPITAL, EDINBURGH; DAVIDSON RESEARCH FELLOW, BACTERIOLOGY DEPARTMENT, EDINBURGH UNIVERSITY.

Exploratory puncture of the pleural cavity has been employed as an aid to clinical diagnosis for many years, and its value has been well established. Exploratory puncture of the lung substance, on the other hand, has been used but seldom, and its value as a clinical procedure has neither been generally advocated nor established. In 1909, Horder [1] described lung puncture as "a new application of clinical pathology," and showed that in cases of pneumonia, of abscess of the lung, and of bronchiectasis lung puncture could be of the greatest assistance in arriving at a diagnosis. In 1920, Thomas and Parker [2] studied the results of "ante-mortem" lung puncture in an attempt to throw some light on the mechanism of crisis in lobar pneumonia, and showed that the death of the pneumococcus was not the factor which causes or initiates crisis. These results do not concern us at the moment; the point of interest about their work and that of others [3] is that lung puncture was performed in a large number of cases, often many times in the same patient, without any evidence to show that it was either a hazardous procedure or associated with any serious complication.

In the Royal Infirmary, Edinburgh, during the past winter, a number of cases of acute lobar pneumonia have been treated with an antiserum for Types I. and II. pneumococcus. As this serum was expensive and difficult to obtain in large amount, it was essential that its use should be strictly limited, if possible, to cases of infection by these types. Accordingly, an attempt was made to ascertain the type of organism at the earliest opportunity. By the usual means of determining the serological type of pneumococcus in sputum,[4] the necessary information on this point was obtained within 6 to 18 hours after the patient's admission; but in a certain number of cases—most frequently those admitted at an early stage in their illness—no sputum could be obtained for several days, and occasionally not until actually after the crisis. By puncture of the lung substance over the affected lobe it was found that in the majority of such cases a pure culture of pneumococcus could be obtained.

TECHNIQUE OF LUNG PUNCTURE.

The method of puncturing the lung substance is similar to that of pleural puncture. In both cases the site of puncture is determined to a great extent by the physical signs. Generally speaking, where the signs indicate exudate or consolidation, there are chances of obtaining a culture of the organism by puncture over that area. In the clinical examination of 74 patients with acute lobar pneumonia during the past six months, it was noted that lower lobe lesions were present in approximately 90 per cent. of the cases. In each patient on whom lung puncture was performed by the writer, one or other lower lobe was apparently affected at the time of puncture, and the lung substance was entered through the seventh, eighth, or ninth intercostal space posteriorly in the mid-scapular line.

The needle is an ordinary exploratory needle of rather fine bore, about 10 cm. in length, attached to a 20 c.cm. Record syringe with a well-fitting piston. The skin is cleansed in the ordinary way, and local anæsthesia with 2 per cent. novocain is induced at the selected site. The needle is then inserted directly into the lung substance for 8 to 10 cm., and the piston slowly pulled back. As the result of suction one or two drops of blood-stained fluid may occasionally enter the syringe. The needle is now gradually withdrawn and, as the pressure becomes lower, some drops of fluid spurt into the barrel of the syringe. This fluid, which may amount only to one or two drops in the needle, is then mixed with 5 c.cm. of phosphate broth (pH 7·6–7·8), 1 c.cm. of this mixture being immediately injected into the peritoneal cavity of a mouse and the type of organism determined in the usual way.

RESULTS IN PRESENT SERIES.

Lung puncture was performed in 17 cases of acute lobar pneumonia. It was primarily done in patients who had at the time no sputum from which the type of the infecting organism could be determined.

Table I.

Case.	Day of illness on day of admission.	Lung puncture fluid type.	Day of admission when puncture performed.	Sputum type.	Day of illness when sputum obtainable
1	2	I.	2	—	—
2	2	I.	1	I.	4
3	4	—	1	II.	6–7
4	3	I.	1	—	—
5	2	—	1	—	—
6	3	II.	2	II.	4
7	4	I.	2	—	—

Table I. shows a group of seven cases which had no sputum at the time of admission. In five of these a positive culture of pneumococcus was obtained from lung puncture. Two cases yielded no growth of pneumococcus, either by mouse inoculation or by direct culture. Sputum was available at a later date from one of these cases; the other patient had no sputum at any time during the course of his illness and in that case, therefore, the type of pneumococcus was not determined. Of the seven cases three eventually had sputum, and the type of pneumococcus present was found to be the same as that demonstrated by lung puncture. In four cases no sputum was obtained at any time during the course of the illness, and in these cases the type of pneumococcus was determined from lung puncture alone.

Table II.

Case.	Day of illness on day of admission.	Type of pneumococcus. Sputum.	Type of pneumococcus. Lung puncture fluid.	Case.	Day of illness on day of admission.	Type of pneumococcus. Sputum.	Type of pneumococcus. Lung puncture fluid.

9	5	I.	I.	13	4	II.	II.
10	5	I.	I.	14	2	I.	—
11	3	II.	II.	15	3	II.	II.

Table II. represents a group of eight cases where sputum was obtainable from the beginning of the illness. Lung puncture was performed to confirm if possible the type of pneumococcus found in the sputum, and in six of the cases the same pneumococcus was isolated by inoculation of a mouse. In the two negative cases no growth of pneumococcus or other organism was obtained from lung puncture; in one case the puncture was completely "dry," but in the other some blood-stained fluid was present in the syringe after puncture.

Case 16 (Table III.), a youth of 23, was admitted on the third day of his illness. From sputum, blood, and lung

puncture fluid a Type II. pneumococcus was obtained. The patient died three days later, and post mortem lung culture also showed a Type II. pneumococcus.

TABLE III.—*Results of Bacteriological Examination of Two Fatal Cases.*

Case.	Day of illness on day of admission.	Type of pneumococcus.			
		Sputum.	Lung puncture fluid (ante-mortem).	Blood culture.	Lung culture (post mortem).
16	3	II.	II.	II.	II.
17	5	I.	I.	I.	I.

Case 17, a woman of 48 years, was admitted on the fifth day of her illness. Similarly, from sputum, blood, and lung puncture, a Type I. pneumococcus was obtained, and at post mortem a Type I. organism was found on lung culture.

A pneumococcus was isolated from the "lung fluid" of 13 out of 17 cases. In each case, in addition to the animal inoculation method, the lung fluid was cultured on blood-agar. In four cases there was no growth; in eight cases a pure culture of pneumococcus was obtained; and in five cases a culture of pneumococcus was found, with an additional growth of staphylococcus. In the four cases where no growth was obtained lung puncture was performed on the first day of admission. The physical signs at that time were not a definite indication of the location of the disease, as is often the case in the first two or three days of a deep-seated pneumonia, and the only clue to the site of the pneumonia in three of the cases was the presence of pain over a particular area of lung. No further puncture was performed in any of these four cases. It may be concluded, therefore, that in these cases the site of puncture did not coincide with a focus in the lung where living pneumococci were present in sufficient numbers to be demonstrated by cultural methods.

The question has arisen from time to time whether the strain of pneumococcus isolated from sputum is identical with the strain responsible for the actual pulmonary lesion, particularly when the sputum strain is a Type IV.—that is, a type which so often occurs as a commensal in the throat. It is only on the rarest occasions that a Type I., II., or III. pneumococcus can be demonstrated in the lung lesion post mortem when during life the only pneumococcus isolated from repeated examinations of the sputum has been a Type IV. The results, therefore, are of interest in showing how the type isolated directly from the lung during life corresponds to that found in the sputum. In the two cases noted in Table III. the pneumococcus isolated from the sputum, lung fluid, and blood during life was found to be similar in type to that demonstrated in the lung substance post mortem, again showing that the type of pneumococcus found in the sputum in acute lobar pneumonia is most probably the same as that causing the lesion.

POSSIBLE DANGERS.

After Horder's description of the procedure in 1909 a certain amount of criticism was evoked, mainly on the ground that the procedure was dangerous. THE LANCET suggested in an editorial[5] that "the occurrence of hæmorrhage from wounding a vessel or an aneurysm of the pulmonary artery" was a disadvantage which had to be taken into account. But even if a vessel of moderate size were punctured by a fine-pointed needle the resultant hæmorrhage would probably be of little clinical or pathological significance. Aneurysm of the pulmonary artery, too, must be of the greatest rarity. In septic pneumonia, infection of a healthy pleura might be a possibility, but in pneumococcus pneumonia it is difficult to see how any further infection of the pleura could possibly occur by its transitory puncture with a well-sterilised and fine-pointed needle. Sudden death caused by reflex inhibition of the cardiac and respiratory centres, due to irritation of the afferent fibres of the vagus, has also been suggested as a real though somewhat rare and uncommon danger.[6] It is improbable, also, that a condition of artificial pneumothorax could be induced, particularly if a fine needle is used, attached to a syringe with a well-fitting piston.

In the present series of cases no complication, direct or indirect, was noticed as a result of lung puncture. At the time of puncture no phenomenon such as increased dyspnœa, troublesome cough, or marked increase in the pulse and respiration-rate was noted. In almost every case pain, either at the time of puncture or after, was negligible. Occasionally short stabbing pain was experienced when the needle penetrated an inflamed and over-irritable pleura, but it was only momentary and of no marked clinical significance. Owing to the fact that puncture was usually performed in a patient too ill to realise exactly what was happening, the psychological factor of expectancy was, in the majority of cases, absent.

CONCLUSIONS.

In cases of acute lobar pneumonia without sputum, or with very little sputum, where for therapeutic reasons it is desirable to know the type of organism as soon as possible, lung puncture may be of value, and in some cases may be the only way to ascertain what type of pneumococcus is present.

GLANDULAR FEVER.

AN EXPERIMENTAL INVESTIGATION.

BY J. O. W. BLAND, M.B.CAMB.,
FREEDOM RESEARCH FELLOW, HALE CLINICAL LABORATORY, LONDON HOSPITAL.

RATHER towards the end of the epidemic of glandular fever that occurred in London in the early months of this year I undertook an experimental investigation of the disease by culture and animal inoculation. The results were of a negative kind, with the exception of the case of one rabbit that was inoculated with the citrated blood of a man suffering from typical glandular fever.

Disease of Rabbits following Inoculation of Human Blood.

This rabbit (CL 320) developed a condition characterised by fever, leucopenia, and anæmia. Fever, between 105° and 106° F., and anæmia with signs of ill-health and wasting, began between the eleventh and twelfth days after inoculation, and lasted until the twenty-second. Thereafter the rabbit became well again and appeared to make a complete recovery. By means of the citrated blood of this rabbit, taken

on the sixteenth day at the height of the fever, this condition was readily transmissible to other rabbits, and has been carried through eight passages, including in all 21 animals that have contracted the disease.

Apart from the first two passages, which showed some unusual features, the course, symptoms, and post-mortem appearances of this disease have been remarkably constant,

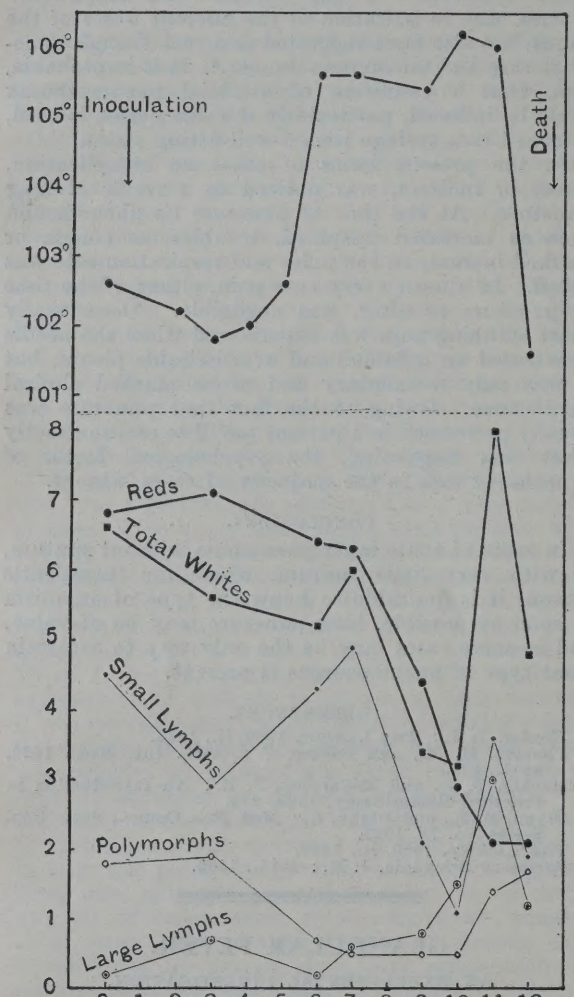

Chart of temperature and blood picture. The ordinates refer to days after inoculation, the abscissæ to total number of cells per c.mm. in millions for red cells and thousands for whites. Large lymphs include monocytes. The upper half gives the temperature in degrees Fahrenheit with the thermometer 6·5 cm. in the rectum.

and are of the following nature: There is, first, an incubation period during which the rabbit seems well, and the temperature remains at its normal level, which may vary in individual cases from about 101°–103° F. During this period the erythrocyte count normally shows a slight increase, while the leucocytes remain fairly steady in both absolute and relative numbers. There follows an abrupt rise of temperature, which in one or two days reaches 105–106·5° F., where it remains some three to six days. During this febrile period the animal swiftly deteriorates, and it becomes thin, weak, apathetic, and short of breath, and looks extremely ill. The red cells fall rapidly to between two and three millions, and there is a leucopenia with an absolute increase of monocytes and, sometimes, of large lymphocytes. The terminal period is ushered in by a rapid fall of temperature to a normal or subnormal level, and the animal dies between the tenth and twelfth days after inoculation. A terminal leucocytosis has once or twice accompanied this period, but leucopenia is the rule.

The most constant features in the symptomatology are the incubation period, the rapid rise and rapid fall of temperature, and the rapid fall of the erythrocyte count. The white cells do not show such constant variations, and for the diagnosis of the experimental disease it has been found that a combined red cell and temperature chart is sufficient. An illustrative chart of temperature and blood picture is given on this page; the actual figures of the blood counts in the table. This chart and table refer to rabbit CL 348 of the fifth passage. The animal was inoculated on July 5th with 7 c.cm. of infected blood by the intravenous route. It presented typical symptoms, and died during the night of July 17th and 18th. At the post-mortem there was the typical enlargement of spleen and liver with focal necrosis but the glands were not enlarged.

Table of Counts made on Blood taken from Ear-vein of Rabbit CL 348.

POST-MORTEM FINDINGS.

Post mortem in this disease one finds considerable wasting, and there is little fat in the subcutaneous tissues or mesentery. The *peritoneum* contains no excess of fluid and is normal. The *spleen* is greatly enlarged—a typical one measured 7·5×1·9×1 cm. and weighed 6·6 g. The colour is a deep reddish purple, the texture fairly firm. The organ is studded with large numbers of white nodules from pin-head size up to 0·4 cm. diameter. These are rather harder than the pulp, and when a piece of spleen is ground in the mortar the resulting paste is granular, like cod's roe, on account of them. The *liver* is usually enlarged and a pale brown in colour, with well-marked lobular pattern. It is studded throughout with yellowish-white flecks and nodules of irregular shape and size, from pin-head up to 0·4 cm. diameter. The *stomach* is normal, but the rest of the gut varies in appearance. It is sometimes normal, and sometimes shows signs of enteritis. In this connexion it must be noted that an epidemic of diarrhœa was present among the normal stock rabbits throughout this investigation. The other abdominal organs are normal, with the exception of the testicles in male animals, which are frequently very small and may measure only 2·6×0·6×0·7 cm. The *tongue*, *larynx*, *trachea*, *pleuræ*, and *pericardium* are normal. The *lungs* are frequently very pale, collapsed, and œdematous, oozing froth and blood-stained fluid from the cut surface on pressure. Once only were nodules found in them similar to those in the spleen and liver. The *heart* is normal. The *brain* is normal. The *marrow* of the femur is deep red and very soft and friable and can only be peeled out from the cracked bone with difficulty. The *lymphatic glands* are in most

ases enlarged throughout the body, and sometimes how injection. Glands from the groin have measured ·8×0·4×0·3 cm., as against the normal for this ite of 0·5×0·2×0·1 cm. Of the post-mortem findings he enlargement and nodular condition of the liver nd spleen is invariable. The glandular enlargement s less so. The other features are variable.

A detailed investigation of the history of the rgans has yet to be completed, and the findings will e reported later. From what histology has been one it appears that the nodules in the spleen are nassive focal necroses of the pulp, around which here is little reaction. The lymphoid tissue is little ffected, and the organ contains much blood and ppears to be stuffed with red cells. In the liver there re also foci of necrosis, and there is more or less roliferation of the reticulo-endothelial cells around he portal spaces, which are infiltrated with lympho-ytes. The condition of the enlarged glands is nteresting for its resemblance to that of human lands from cases of glandular fever—namely, that here is a proliferation of the reticulum cells and the ells of the lymph sinuses. This is not as marked as n the human glands, and the more acute nature of he disease in rabbits may account for this. In some f the glands there are foci of necrosis surrounded by zone of proliferated reticulum cells.

Attempts to cultivate an organism from the blood nd organs of these rabbits have failed. On six ccasions blood used for passage with a positive result as been cultured by a variety of aerobic methods, nd on five of these it was sterile. On the sixth was btained a Gram-positive spore-bearing bacillus with spreading, dry, arborescent habit of growth on agar —an obvious air contaminant. Organs from 11 cases ave been cultured by aerobic methods, and in the najority of cases have been sterile. Where organisms ave been grown they have either been of an intestinal ype, presumably agonal invaders, or else obvious ir contaminations. No one type of organism has een constantly present. Further attempts to grow he infective agent will be described later.

Nature of the Disease.

The question arises whether this condition (which or convenience and without any pre-judgment of its rue nature will be spoken of as experimental landular fever) is identical with the human disease r whether it is a natural disease of rabbits that was roused by the inoculation of human blood. Two onditions have been described which resemble it nore or less closely: (1) Infection with the *Bacterium nonocytogenes* of E. G. D. Murray, R. A. Webb, and . B. R. Swann [1]; and (2) the natural disease of hares escribed by K. Aoki, S. Kondo, and J. Tazawa,[2] hich is due to a filtrable virus and which is infective or man, rabbits, guinea-pigs, and mice.

1. The presence of a monocytosis, focal necroses in the ver and spleen, and enlargement of the lymph glands are ommon to intravenous injection with *B. monocytogenes* and ith experimental glandular fever blood, but here the esemblance ends. In *B. monocytogenes* infection there is a eucocytosis, the serous cavities almost always contain large amount of exudate, and the subcutaneous tissues are ften œdematous. On the other hand, leucopenia is the ule in experimental glandular fever, and exudates in the erous cavities and œdema of the subcutaneous tissues have ever been seen. Moreover, in the fairly extensive series of ultures made from infective blood and from the organs ost mortem the *B. monocytogenes* has never appeared. t may be taken as improbable that there is any relationship etween the two diseases.

2. The disease described by Aoki, Kondo, and Tazawa auses in man a fever of short duration, followed by painful welling of the lymph glands. In rabbits it produces a high fever which is rapidly fatal, and there are sometimes, but not regularly, enlargement of the spleen and liver, with the presence of submiliary nodules, and swelling of the lymph glands. Nodules were most common, however, in the peritoneum, and were often so numerous as to cause a matting together of the abdominal organs. In experimental glandular fever no case has been seen with nodules in the peritoneum, while they have been constantly present in the liver and spleen. Aoki, Kondo, and Tazawa were able to cause their disease not only with infective blood but also with suspensions of organs, but attempts to do so with experimental glandular fever have so far failed. Spleen has been tried four times, liver twice, and brain once. Aoki, Kondo, and Tazawa do not record the blood picture in their cases nor the histology—at any rate in their German papers. In the absence of these it is difficult to assess the relationship of their disease to experimental glandular fever, but if the two conditions are related they do not seem to be identical.

[1] Jour. Path. and Bact., 1926, xxix., 407.
[2] Centr. bl. f. Bakt., 1928, cv., 252.

There remains the possibility that experimental glandular fever is a natural disease of the rabbit, hitherto undescribed, that was aroused by the intravenous inoculation of human blood. To test this possibility four normal rabbits were inoculated with four normal human bloods. None of these rabbits showed any sign of disease. One, however, died seven days after inoculation from hæmopericardium following cardiac puncture. Of four further normals inoculated with the bloods of the previous rabbits one died, after two days, of enteritis, and there were no signs of experimental glandular fever; another died after three days in similar fashion; the third died after 19 days, also of enteritis, having shown no signs of experimental glandular fever during life or post mortem. The fourth animal remains alive and has been normal throughout. These three unsatisfactory deaths make it imperative that further controls should be done.

It is obviously impossible at present to conclude that the experimental and the human disease are the same. That experimental glandular fever followed the inoculation of the blood of a human case; that it is a disease characterised by fever and by swelling of the lymph glands; that it causes a profound disturbance of the blood picture; and that the histology of the enlarged glands shows features resembling human glands from glandular fever suggest the identity of the two diseases. On the other hand, it must be recognised that experimental glandular fever has been obtained from the blood of only one human case. The bloods of four other cases have been tried without success. Of these cases, however, three were possibly non-infective, since they had been ill some time and were afebrile when the blood was taken. The remaining case was early and febrile. The rabbit that received the blood (CL 321) showed a short period of low fever between 104° and 105° F. for seven days, and aborted on the third day of fever. Coincident with the febrile period there was a slight fall in red and white cells, but the picture was insufficient to suggest at the time an attempt at passage with the blood, and the opportunity was unfortunately missed. The temperature chart and blood picture are now seen to be suggestive of experimental glandular fever.

In order to settle the question of the identity of the human and experimental diseases, blood from further acute cases in the febrile stage is wanted and will be examined when it is available. This investigation and others on the nature of the infective agent, on its viability, cultivation, and filtrability, and on the histological features of the disease will be reported in subsequent papers.

Summary.

1. Inoculation of the blood from a human case of glandular fever into a rabbit was followed by a disease which is transmissible to other rabbits by the

citrated blood. 2. This disease is characterised by fever, anæmia, leucopenia, and monocytosis, enlargement of the lymph glands, spleen, and liver, and the production of focal necroses in them. 3. The relationship of this disease to human glandular fever is discussed. 4. The name "experimental glandular fever" is suggested for the disease in rabbits.

My thanks are due to Dr. S. P. Bedson for his advice throughout this investigation, and to my clinical colleagues for access to their cases.

CLINICAL AND LABORATORY NOTES

AN APPARATUS DESIGNED TO DIMINISH THE INCIDENCE OF POST-OPERATIVE THROMBOSIS.

By L. R. Braithwaite, F.R.C.S. Eng.,
HON. SURGEON, LEEDS GENERAL INFIRMARY.

In The Lancet of July 12th appears a short article by Dr. C. A. J. Quant (Holland) entitled the Prevention of Thrombosis. Dr. Quant lays stress upon the "slowing of the blood stream as one of the most important of the possible causes of coagulation," and also indicates that the lower abdomen (especially the left side) is probably the usual site of the thrombosis. In recent years Waltman Waters, of the Mayo Clinic, has written on the subject of fatal pulmonary embolism, and in *Surgery, Gynecology, and Obstetrics*, January, 1930, will be found a modern summary of the methods of reducing its incidence. Dr. Waters states that at the Mayo Clinic the average incidence of fatal post-operative embolism from 1917 to 1927 was 0·34 per cent. The result of "the use of a regimen directed towards increasing the rate of metabolism, of blood pressure, and of blood flow in 4500 major surgical procedures of comparable type (to those of 1917 to 1927) during the last 4½ years has been followed by an incidence of fatal pulmonary embolism in less than 0·09 per cent. of cases." This is indeed a wonderful record and it is of interest to recall the means adopted.

Eliminating the bad risks which, of course, can be and will be guarded against, the method in use at the Mayo Clinic appears to be: 1. The decrease of metabolism and of blood pressure and the slowing of the circulation are combated by giving tablets of desiccated thyroid gland grs. 2 three times a day. 2. Patients are urged to move in bed, flex arms and legs, and especially to turn themselves from side to side (Wilson-Pool).

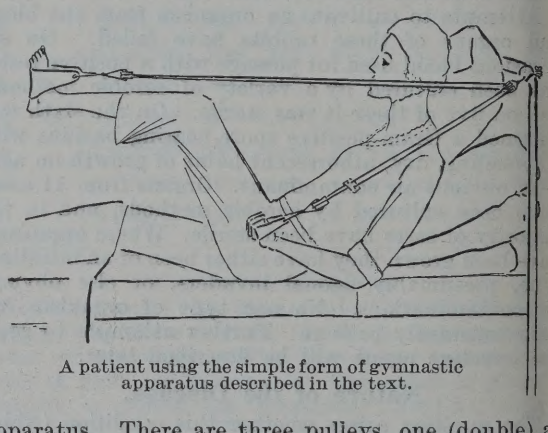
In a discussion following the presentation of Waters's paper Dr. Miller, of Chicago, stressed certain additional points: (1) careful pre-operative study, especially in old people, and the administration of digitalis as a cardiac stimulant; (2) careful operative technique; (3) particular attention to the fluid intake; (4) avoidance of tight bandages, especially near the chest; (5) systematic exercises, and especially daily elevation of the foot of the bed.

Dr. David, of Chicago, commented on the apparent increase in the frequency of the condition; in America it appears to vary from 1 to 3 in 1000 cases, and in Germany there has been an extraordinary increase during the last seven years. Has such an increase occurred in this country? It is very difficult to get any statistics from hospitals, because the cause of mortality is rarely given. My own impression is that there has certainly been an increase in private practice, probably entirely due to the "perfection" of modern nursing. I do not think the catastrophe ever occurred so frequently in hospital, where patients had to "fend for" themselves, and I do not think it is anything like so frequent now.

POST-OPERATIVE EXERCISE.

I have tried the thyroid treatment for the last two years, and regretfully say I have still had catastrophes. For many years I have advocated almost an "ambulatory" post-operative regimen—particularly in prostate cases—and I have been very pleased with it, both for the early closure of the wound and for freedom from thrombosis. One cannot, however, apply the "ambulatory" treatment to a gall-bladder or a stomach case, or after a big lower abdominal operation.

During the last 18 months I have been using in my private practice a very simple form of gymnastic



A patient using the simple form of gymnastic apparatus described in the text.

apparatus. There are three pulleys, one (double) at the head and one each (single) at foot and hand. The apparatus is fixed to the head rail of the bed and is used first on one side and then on the other. A light cord is treaded through the pulleys as shown in the sketch, and there is a means of lengthening or shortening the length of the cord. The stirrup and handle are of soft, well-padded canvas. We use it for all abdominal operations, beginning as a rule on the fourth day. Some patients will try it earlier and others cannot and will not use it until later; some will not use it at all. At the beginning the patient can only exercise for about two minutes, but the time soon arrives when they are able to work the apparatus for five minutes at each side. In some cases they enjoy the exercise very much indeed, and will ask for it and work it for longer periods. The idea underlying the exercises is to prevent stagnation of blood, especially in the pelvis and lower abdomen. By pushing with the hand the leg is pulled well up to the abdomen and at the same time very good exercise is given to the arm. In practice it is found that the patient is best in the position shown in the sketch, and under these conditions there appears to be little if any painful drag on the abdominal wound. We find people who have assiduously carried out these daily "jerks" are not only happier for it whilst in bed but that when the time arrives to get up they are much more able to move about.

The apparatus is designed to "force" a patient into systematic activity at an early stage in recovery. It is to simulate the enforced movements which must be made in a hospital—to negative, if you will, the bodily comfort so ably dispensed in modern nursing. Done under the guise of "physical jerks" the exercises offer a very considerable temptation to most of our patients, and particularly to that class who need it most. The apparatus is made for me by Chas. F. Thackray, of Park-street, Leeds.

PURPURA SIMULATING THE ACUTE ABDOMEN.

By Ian Fraser, M.B., M.Ch. Belf., F.R.C.S. Eng. and Irel.,

ASSISTANT SURGEON, BELFAST HOSPITAL FOR SICK CHILDREN.

Purpura has always been recognised as a disease by which a reputation could be made or marred. The text-books stress the point, and probably every surgeon who has opened many children's abdomens has at some time fallen into the trap. For two cases of purpura to occur within a week or so of each other in the same hospital, and for both to be operated upon, is, I think, sufficiently interesting (or distressing) to merit publication.

Case 1, a small boy, between 8 and 9 years old, was brought to hospital with a 12-hour history of abdominal colicky pain, intermittent in character, with the passage of blood. No tumour was palpable by abdominal examination. He had vomited several times, his pulse had mounted, and his temperature was subnormal. By artificial light his body appeared, without intimate inspection, to be normal. On rectal examination the finger was found to be covered with blood; considering his age, the history, the temperature, the presence of vomiting, and the rectal findings—notwithstanding the absence of the sausage tumour and the *signe de Dance*—a diagnosis of intussusception was made with confidence. Mr. H. P. Hall operated; free fluid was found in the peritoneal cavity, and the gut wall and mesentery were studded with petechial hæmorrhages and ecchymosed patches. The appendix was removed and the wound closed in layers without drainage. The child made an uneventful recovery and convalescence. Careful examination later revealed many minute small hæmorrhagic points which had escaped notice with artificial light. These pin-point hæmorrhages were more marked during the convalescent period.

Case 2 was equally interesting, especially as it followed closely on the first case, which had made everyone on the alert for the possibility of purpura. The patient, a little girl of 12, was admitted in the late afternoon with a history of having been taken ill two and a half days previously with generalised abdominal pain, followed some hours later by vomiting; for the last 24 hours the pain had been in the right iliac fossa. On examination by artificial light her pulse-rate was 120, her temperature 97° F., her tongue was dry and coated, and her breath foul. The abdomen was tender all over, especially over the appendix, and definitely rigid over McBurney's point. The chest and heart were normal. A rectal examination revealed a tender mass in the cæcal region. She thought she felt more comfortable since the morning; this ease had come on fairly rapidly. The only item of interest was that she thought her left foot and right wrist had swollen the last day or two, but there was nothing gross to be seen in them. Her urine was normal.

The diagnosis of acute gangrenous appendicitis was made, and I was rather inclined to think that it had perforated, considering the facts that she had become very much easier, that the pulse-rate had risen and temperature fallen, and also that the tongue was very dry and furred. She had been ill two and a half days, and was now rigid.

A muscle-splitting gridiron incision was made in the right iliac fossa under chloroform and ether. A large quantity of non-purulent blood-stained fluid escaped. The last two feet of the ileum were brilliant scarlet in colour and showed numerous small black areas of hæmorrhage. The gut wall was markedly thickened with the blood contained in the tissues, a condition which, I suppose, explained the mass felt per rectum. The hæmorrhage stopped more or less abruptly at the ileocæcal valve, leaving the cæcum almost normal. The appendix—perfectly harmless and beyond reproach—was removed. It was normal in every respect except that it contained a rich supply of thread-worms. The rest of the ileum was mottled, the mottling gradually decreasing towards the jejunum. There were several enlarged mesenteric glands, some soft and others calcified. An examination of the abdominal viscera through this limited incision failed to reveal any further pathology. The abdomen was closed in layers, with a small wick drain to allow the blood-stained fluid to escape.

Recovery was complete and convalescence normal, except for the following incidents. For three or four days after the operation the motions were mixed with dark blood, and on the third day the urine was heavily tinged with blood. The post-anæsthetic vomit contained blood and the saline returned after operation was also tinged. On about the tenth day she had a severe attack of epistaxis, and about the same time a marked purpuric rash appeared, involving both feet and the outer sides of the ankles. This was so severe that the feet were almost blue. There was also considerable swelling of the ankles.

A blood examination made after the operation was as follows: Blood film—marked preponderance of mononuclear cells. Differential count: mononuclears 35 per cent.; large lymphocytes, 22 per cent.; small lymphocytes, 8 per cent.; polymorphonuclear leucocytes, 35 per cent. Coagulation time, five minutes. Blood-platelets, 114,000 per c.mm. Red blood cells, 5,500,000. White blood cells, 16,500.

These two cases are of interest, in that the internal manifestations were well marked while outward signs were absent or slight. That two such cases should occur within such a short time is worthy of note, and that both should be operated upon merely lends support to the fact that purpura can simulate the acute abdomen very closely. In the two examples quoted it will be seen that the main external diagnostic signs of purpura were well marked after the operation, although almost absent before.

Although both children were operated upon at a time when they certainly had a tendency to bleed, there were no troubles of any sort with wound-oozing or hæmatoma formation. Both wounds healed well; the second showed a slight keloid formation.

TRIKETOHYDRINDENEHYDRATE

AS A REAGENT FOR ALBUMIN, PEPTONE, AND AMINO-ACIDS.

By Hermann Gardner, D.Sc.,

HEAD DISPENSER, QUEEN MARY'S HOSPITAL, STRATFORD.

During an investigation involving the application of tests for proteins and amino-acids, I used a reagent discovered by Ruhemann and advocated in text-books,[1] which has found some usage in clinical laboratories—namely, triketohydrindenehydrate, or ninhydrin. It was noticed that, whilst ninhydrin gave positive indications, no confirmation could be obtained with Millon's reagent or by the biuret or xanthoproteic reactions, nor could amino-acids be isolated by acidulation and esterification in the usual manner. Baumann and Schotten's reaction also failed to reveal the presence of amines. This apparently paradoxical behaviour seemed only to be explicable on the assumption that the ninhydrin reaction was produceable by other than the products of hydrolysis of proteins.

A series of experiments was conducted with dilute ammonium salts in feebly alkaline solution (0·2 to 0·4 per cent. NH_4NO_3 or $(NH_4)_2SO_4$ and 0·04 to 0·1 per cent. $NaHCO_3$). Attention was arrested by the colour reaction these solutions afforded with ninhydrin, mostly a purplish red, which gave the distinctive blue on the cautious addition of very dilute hydrochloric acid. Reference to the published monographs of Harding and Warneford,[2] and of Harding

and MacLean,[3] confirmed the observation to a certain extent—namely, that "all ammonium salts *under the right conditions* are capable of giving the ninhydrin reaction. These conditions *appear* to be a faint alkalinity of the solution." (The italics are mine.)

Actually, alkalinity tends to produce a magenta or purplish red coloration rather than the typical blue, which only appears, as stated, on nearly neutralising the solution. Free ammonia in some amount appears to interfere with the reaction. It seems as if the colorations noted result from ammonium hydroxide in too great amount (although actually but small in proportion) masking the true (or blue) colour resulting from the interaction of NH_3 ions and the reagent. That the interaction is due to ammonia in the ionised state is indicated by the fact that an ammonium salt in very dilute solution will not react with ninhydrin even on boiling, but if a trace of sodium carbonate be added, the blue colour is produced on the addition of the reagent.

An ammonium salt in solution in the presence of alkali, in however small a quantity, indubitably undergoes partial—if but minute—decomposition, and the extreme dilution of itself tends towards ionisation.

If the hypothesis advanced is correct, obviously the presence of ammonia (NH_3) itself in minute amount in an aqueous medium should yield the distinctive reaction. Numerous solutions were prepared and tested, commencing with 0·5 c.cm. of ammonia solution (sp. grav. 0·888 at 15° C.) in 500 c.cm. of ammonia-free distilled water. This gave a claret-red solution on boiling with 1·0 per cent. ninhydrin, the fine blue colour associated with the test developing on the careful addition of N/100 hydrochloric acid. That the coloration was not due to ammonium chloride per se was subsequently proved.

Ultimately it was found that a dilution of 0·15 to 0·2 c.cm. of ammonia solution (sp. gr. 0·888) in 500 c.cm. reacted perfectly to the test—namely, 3 c.cm. of this dilution mixed with 1 c.cm. of 1 per cent. ninhydrin solution, boiled for two minutes, diluted with an equal quantity of distilled water and observed in a white glass tube of 8 mm. diameter by transmitted light, or against a white tile, exhibits the characteristic ninhydrin blue coloration. That is to say, water containing 0·00865 per cent. NH_3, or in 1 c.cm. 0·77 mg. NH_3 nitrogen, responds to the reaction.

SUMMARY.

Triketohydrindenehydrate is not a reliable reagent for the products of hydrolysis of protein generally. The colour reaction is almost certainly due to the presence of traces of free ammonia, or of NH_3 ions, and is masked by ammonium hydroxide (NH_4OH) or by alkali in excess.

Traces of alkali merely promote the reaction through causing the liberation of NH_3 ions from an ammonium salt. No doubt such ions appear amongst the hydrolysis products of protein in the presence of water, hence the reaction.

Ninhydrin, unlike Nessler's solution, is unaffected by ammonium salts in solution.

REVIEWS AND NOTICES OF BOOKS

A Text-Book of Hygiene.

By J. R. CURRIE, M.D. Glasg., D.P.H., M.R.C.P. Edin., Professor of Public Health in the University of Glasgow. Edinburgh: E. and S. Livingstone. 1930. Pp. 844. 27*s*.

A Synopsis of Hygiene.

Third edition. By W. WILSON JAMESON, M.D., M.R.C.P., D.P.H., Barrister-at-Law, Professor of Public Health, London University; and G. S. PARKINSON, D.S.O., M.R.C.S., L.R.C.P., D.P.H., Assistant Director of Public Health Division, London School of Hygiene and Tropical Medicine. London: J. and A. Churchill. 1930. Pp. 541. 18*s*.

Prof. Currie's new text-book is intended for medical students engaged in studying hygiene, but is also meant to be of service to candidates for the diploma in public health. In the range of subjects dealt with it should more than satisfy the present requirements of any examining body for a medical qualification, and will go a long way towards meeting the more detailed wants of the post-graduate student. The sections on air and ventilation, warming and lighting, soil, water-supply, refuse, and sewage disposal are well written and free from many of the obsolete notions which too often make their appearance even in first editions. The question of river pollution is well reviewed and the events which have led up to the present unsatisfactory position are briefly summarised. The public health law (both English and Scottish) is described fully in each section, an arrangement which is convenient for the student. A short summary of the Local Government Acts of 1929 for both countries is also included. The chapter on epidemiology is comprehensive, noting the main theories of the epidemic which have been put forward since the time of Hippocrates, and including a reference to the modern experimental work of Topley and Greenwood.

There are certain omissions and defects which deserve comment. No reference is made either to the dangers of polluted swimming baths or to the practice of continuous filtration which has now been so widely adopted in public bathing installations. The sections dealing with maternity and child welfare and school hygiene are disappointing. Amongst the subjects requiring more detailed consideration are nursery schools, the duties of health visitors, and the provision for physical and mental defect in school-children. Except for a passing note the important subject of mental hygiene is ignored. A bibliography might have been useful, especially since some dogmatic statements made are not in accordance with accepted teaching. The standard of allowable respiratory impurity set out differs from that of de Chaumont, and a rather sweeping assumption concerning the capacity of crevices and chinks as air inlets is put forward. No authority is quoted for the estimate of 3 per cent. as the incidence of chronic carriers of amœbic dysentery in the United Kingdom. Generally, as in most text-books of hygiene, even those purporting to be modern, there is too much bias on the environmental hygiene side compared with the manifold problems of individual hygiene which

o-day form so large a part of the work of a public ealth department.

In many other respects the book is well up to date, eferences to psittacosis, undulant fever, post-vaccinal ncephalitis, the serum treatment of anterior polio-nyelitis and measles are included. The subject of tatistics is adequately dealt with, and the review of tatistical methods should be sufficient for candidates or degrees or diplomas in public health.

The new edition of the popular synopsis of hygiene, n the preparation of which Lieut.-Colonel Parkinson akes the place of Mr. F. W. Marchant as Prof. ameson's collaborator, includes reference to the more utstanding changes in public health administration hich have taken place since the appearance of the econd edition. Of these, the most important and ar-reaching is, of course, the Local Government Act, he main provisions of which are briefly set out. The ecommendations of the Ministry of Health Committee n Vaccination and the provisions of the Vaccination rder, 1929, are also noted and the instructions to accinators contained in the first schedule of the rder are given in detail. The provisions of the ood and Drugs (Adulteration) Act, 1928, are well ummarised. The whole work bears evidence of being horoughly revised and brought up to date. The uthors do not claim that the book is anything but a ynopsis, but the reader will find that it is also a very seful index to modern public health literature. The ection on vitamins is an admirable résumé of the resent position. The chapter dealing with vital tatistics has been rewritten and is one of the best in he book.

Treatment of Children's Disease.

By Prof. F. LUST (Karlsruhe). Translation of Sixth edition with additions by SANDOR A. LEVINSOHN, M.D. (Paterson, N.J.). London: J. B. Lippincott Company. 1930. Pp. 513. 30*s*.

ALTHOUGH text-books of pædiatrics are numerous, rprisingly few are devoted exclusively to treatment. rof. Lust's work has proved its popularity on the ontinent. This volume is something more than a anslation of the sixth (German) edition, since it has een supplemented by additions made by the author, presenting the advances of the last three years, and so by the translator, introducing modifications in ccordance with current American practice. The rst half of the book deals with individual diseases, short diagnostic summary being followed by an count of the management and treatment of each sorder. The second part, arranged in alphabetical der, is devoted to drugs and formulæ, including reparations used in infant feeding. Close printing d a condensed style have made the volume more mprehensive than its size suggests, and it should of considerable service to practitioners.

iagnosis and Treatment of Heart Disease.

Practical Points for Students and Practitioners. Sixth edition. By E. M. BROCKBANK, M.D. Vict., F.R.C.P., Hon. Consulting Physician, Royal Infirmary, Manchester. London: H. K. Lewis and Co., Ltd. 1930. Pp. 240. 7*s*. 6*d*.

THIS little book is full of useful information. In dition to the usual subject matter found in volumes heart disease, many practical points of real clinical portance are included. For example, in discussing e cardiac impulse and the apex-beat the author ys, "remember the extension outwards of the pulse of a nervous rapid normal heart." He advises that three blood-pressure readings should be taken on every patient, since the first inflation of the armlet is liable to induce some spasm in the artery, especially in apprehensive subjects with quick pulses, leading to too high a reading; many other examples of a similar kind could be given. On the vexed question of the significance of the systolic murmur Dr. Brockbank would have us believe that whenever this is found to be present it is evidence of mitral regurgitation due either to disease of the valves or dilatation of the valve ring; in this his teaching differs from that now widely accepted, that a murmur which is found alike in health and disease cannot have the same significance in every case. The chapter on the heart in school-children is a valuable one; it is good to see stated a fact which is so seldom realised—that the impulse of the contraction of the left ventricle in children below puberty can be outside the nipple line. Equally useful is the chapter on examination for life insurance; the advice to listen to a doubtful heart with the patient lying down as well as standing could usefully be followed in all examinations of the heart. The main criticism to be levelled against this book is that insufficient space is given to important recent developments in diagnosis and treatment of cardiac disease. For example, coronary thrombosis is not given the notice it deserves, and only a scanty paragraph is devoted to the use of the X rays in diagnosis. Dr. Brockbank has, however, offered innumerable practical hints of great value.

Medical Science for All: Man v. Microbes.

By NICHOLAS KOPELOFF. New York: Knopf. 1930. Pp. 319. With 130 figures. 21*s*.

THIS attempt to popularise microbiology is not a great success. It has the worst fault of popular scientific exposition in being ecstatic and exaggerated. The title itself is misleading, for man actually gains much more by the kindly offices of some microbes than he loses by the attacks of others. The first sentence of the preface—"a man is only what his microbes make him"—is nonsense. The book is, moreover, unsound in detail. "Galloping consumption" (p. 105) is not general miliary tuberculosis; oysters (p. 121) do not "float" in sewage when being fattened; de Morgan (p. 197) did not initiate the rhyme about "great fleas have lesser fleas" which dates back at least as far as Jonathan Swift; the precise statements on p. 202 of the minimal fatal doses of toxins for man have no justification; and on p. 176 there is a complete muddle about *Leptospira icterohæmorrhagiæ* and the state of knowledge of the causation of yellow fever at the time of Noguchi's death. In short, the layman who wants to know something about bacteriology will find sounder information at less cost in the Home University Library.

Études sur les maladies familiales nerveuses et dystrophiques.

By O. CROUZON, Physician to the Salpêtrière. Paris: Masson et Cie. 1930. Pp. 385. Fr.55.

COLLECTED into a convenient volume the reader will find a valuable series of papers written during a period of years by Dr. O. Crouzon, all of which bear on questions of familial, in distinction to hereditary, nervous and dystrophic disease. They range widely over the whole field and include both the banalities and the rarities. The intrinsic value of some is considerable; for example, the articles dealing with cleidocranial dysostosis and craniofacial dysostosis

are highly informative, as well as being excellently illustrated, and the same may be said of those devoted to familial ocular affections. Here the neurologist will discover unfamiliar facts of much interest. Similar minute and clear description characterises other chapters concerned with cerebellar atrophies, lenticular degeneration, Friedreich's disease, and myoclonus epilepsy. When, however, the reader seeks instruction beyond the plane of clinical medicine he early becomes conscious of our limitation of knowledge. Dr. Crouzon has endeavoured to work out the application of Mendelian principles to familial disease, collecting from personal observation and the literature the records of numerous families in which disease has appeared on a larger or smaller scale; and in most instances he is compelled to state that the paucity of data prevents definite conclusions from being drawn. He considers, none the less, that in Huntington's chorea, cerebellar heredoataxia, and hypertrophic neuritis Mendelian proportions are observed, and he asserts that they are likely to be found present also in Thomsen's disease, Friedreich's disease, familial tremor, retinitis pigmentosa, familial nystagmus, and periodic family paralysis.

Annals of Roentgenology: The Neck.

Vol. IX. By PERCY D. HAY, Jnr., M.D. New York: Paul B. Hoeber. 1930. Pp. 104. $8.

IT is usual in radiological studies to take an organ or a system and work out the radiology applicable to it. Dr. Hay's method of taking an anatomical region, comprising parts of many systems, is unusual if not unique. It certainly has advantages. The author has worked in a department that serves Dr. Chevalier Jackson's bronchoscopic clinic. This service calls for the utmost detail in the radiological examination of the neck, lest some unsuspected foreign body or pathological lesion should be present, and the number and variety of conditions met with are astonishing. Dr. Henry K. Pancoast, in an introduction, points out that the perusal of Dr. Hay's manuscript brought home to him and his fellow workers the importance of a careful study of the neck of every child submitted to examination for suspected enlargement of the thymus gland—a condition which would appear to be much more common in North America than in this country. The author devotes a special section to the examination of the neck in suspected thymus cases, since high respiration disturbance may be due to non-opaque foreign bodies in the trachea, diphtheria, intratracheal or intra-œsophageal abscess, which must all be excluded before the thymus is incriminated.

The atlas is based on a detailed study of 203 cases, 128 of which were pathological, the remainder being normal children and adults. Fourteen different pathological conditions were met with in the series and these are fully described. The radiography of infants is always difficult and, since dyspnœa is present in so many of the conditions illustrated, to obtain any radiographic result at all is a feat of management and skill. When we think of the difficulties that must have been encountered Dr. Hay deserves praise for his achievement in collecting such a representative series; the radiograms illustrating the various lesions in adults, particularly the stenotic conditions, are exceedingly good.

Although this volume is smaller in scope than its companions it is worthy in every way to take its place in this excellent series of monographic atlases.

INTERNATIONAL CONGRESS OF PÆDIATRICS.

STOCKHOLM, AUGUST 18TH–21ST.

(FROM OUR OWN CORRESPONDENT.)

SOME 600 specialists, representative of countrie from America to Japan, attended this Congress, th proceedings of which are to be fully reported in special volume of the *Acta* (*Scandinavica*) *Pædiatrica* which will contain abstracts in English, French, an German. The organisation of the Congress wa admirable, and its success was principally due to th industry and courtesy of the Swedish National Com mittee, whose president was Dr. I. Jundell, an secretary Dr. Nils Malmberg.

Biological Effects of Irradiation.

It may perhaps surprise English practitioners, wh regard rickets as no longer a common disease, tha over a third of the time of the Congress was devote to a discussion on the biological effect of direct an indirect ultra-violet irradiation, with particular regar to rickets. Alfred F. Hess (New York) opene with a paper on the indication for these therapeuti radiations, emphasising their importance in ricket tetany, and osteomalacia. They were of possibl value in dental caries, but in other conditions—fc example, coryza and respiratory affections—he hel them of no avail and possibly harmful. He dre attention to the importance of using an accuratel standardised preparation of ergosterol, especially i experimental work upon the subject. In the discussio which followed the methods of standardisation wer criticised on the ground that rickets in rats could no be compared closely with rickets in man. It wa suggested that the use of a radiation, screened to giv a short band of the spectrum, would produce a pure brand of ergosterol. Faber and Bloch (Copenhage emphasised the distinction between hypocalcæmi rickets, associated with tetany and osteoporosis, an hypophosphatæmic rickets with marked bony ove growth and deformity. H. J. Gerstenberger (Clevelan considered that the high-phosphorus low-calciu form of rickets was becoming commoner owing t insufficient protection.

The Thymo-lymphatic System.

The general facts concerning the metabolism c calcium and phosphorus and their clinical significanc were, apart from rickets, touched on rather lightl in the second session on the thymo-lymphatic systen The subject was opened by J. A. Hammar (Upsala C. Cattaneo (Milan), E. Moro (Heidelberg), and G Mouriquand (Lyon), who dealt chiefly with diagnosi The existence of a clinical entity was agreed, bu opinion varied whether the hyperplasia of th lymphatic system was a cause or an effect of som general metabolic factor, the balance being in favou of the latter view. It was also considered tha *l'état lymphatique avec la mort subite* and the *diathès exsudative* of Czerny, Paltauf, and others were bu different grades of what in England is termed th exudative diathesis.

Psychopathology of Children.

The third subject of discussion was opened b R. D. Gillespie (London) and F. Hamburger (Graz from different points of view. Prof. Hamburge made an effective plea that the pædiatrician shoul

not concern himself too exclusively with the child's body, for it was he who saw most of the psychopathic disorders at a stage when they were comparatively easy to deal with. He was in a position to observe their origins in early infancy, and to distinguish those that were inborn and those that were acquired as a result of early environment. He could mitigate or remove the handicaps encountered by the child when it was beginning to realise that the world contained other persons. Suggestion during the early years of life might determine the course that the child would eventually follow. Present-day physicians and students should attend to this aspect of their duty, although it was not associated with figures and percentages. Dr. Gillespie indicated the lines taken by psychogenic disorders in children, and the symptoms encountered. It was, he said, unwise to interpret the mind of a child in terms of the emotions of an adult, and he did not admit that infantile sexuality played the part in forming the mental make-up of a child sometimes ascribed to it. It was not impossible, he thought, to gain the partial confidence of a child in a clinic with others present; it was therefore desirable for students to attend such a clinic and see for themselves the types of symptoms that were amenable to treatment by the psychiatrist. In the psychopathies of childhood and adolescence the results obtained were equal to those of other branches of medical science. Benjamin (Munich) spoke of the importance of a consideration of the "stubborn phase" (*Trotzphase*) from two to four years of age; many of the neuroses in childhood had their roots, he claimed, in mismanagement at this period of a child's life.

Afternoon Discussions.

During the afternoons group discussions were held. At one of these Ernberg (Stockholm), Wallgren (Goteborg), Alfaro (Buenos Aires), and Johannsen (Goteborg), reported on their studies in *erythema nodosum*. Without exception they considered it to have a tuberculous origin in the majority of cases, the nodules being the manifestation of an anaphylactic reaction to a skin sensitisation. A source of infection could usually be demonstrated. Johannsen maintained that cases of unquestionable rheumatic ætiology were very rare in children, and that in these cases also it was an allergic reaction. Polyarthritic symptoms in association with erythema nodosum were not necessarily rheumatic; cases of acute polyarticular rheumatism with hot swollen joints, which were not pyogenic and did not react to salicylates, should be considered as allergic manifestations of tubercle.

L. G. Parsons (Birmingham) presented a study of the fat metabolism in cœliac disease, in which no evidence was obtained that the increased fæcal fat was due to increased excretion of blood fat. He considered the low fat curve to be the result of defective absorption from the intestine.

S. W. Davidson (Newcastle) described the radiological appearances of five cases of osteochondritis ischiopubica in children between five and eight years, and pointed out the clinical resemblances to early tuberculous hip-joint disease.

J. C. Spence (Newcastle) described 17 cases of nutritional xerophthalmia, and emphasised the significance of skin infections and epithelial cells in the urine as evidence of xerophthalmic diet deficiency. Spence's observations suggested also that the specific food factor involved was not the same as the growth factor or the anti-infective factor for general infections.

B C G VACCINE.

Several reports on the use of B C G vaccine were presented. W. H. Park (New York) said that if as a result of a long series of animal experiments a strain was cultured strictly according to the directions of Calmette there was no danger from increase of virulence. If the method did not provide effective prophylaxis in every case there was, he said, no doubt that a child vaccinated early and carefully protected from contact with tubercle for about two months gained a useful degree of protection against virulent infection in home surroundings. The appearance of a positive Mantoux test was, he thought, the best indication of developing immunity. Drucker (Copenhagen) reported the recovery of tubercle bacilli from the stomach in 100 per cent. of cases of Pirquet-positive children under one year of age. Among these was one child which had been vaccinated with B C G six months earlier, and from whom a bacillus identical with the Calmette-Guérin organism was recovered from the stomach washings.

INTERNATIONAL UNION AGAINST TUBERCULOSIS.

OSLO CONGRESS, AUGUST 13TH–15TH.

In the presence of the King and Queen of Norway, the seventh conference of the *Union Internationale contre la Tuberculose* opened at Oslo on August 13th with a service of music in which the orchestra played Greig's symphonic poem "Spring." Speeches by Prof. Th. Frölich (Oslo), president of the organising committee, and Prof. Léon Bernard (Paris), secretary-general, terminated the formal proceedings.

Preventive Vaccination.

A discussion on preventive vaccination against tuberculosis by means of the Calmette-Guérin bacillus was opened by Prof. A. Calmette (Paris) himself. Immunity against tuberculosis was, he said, determined solely by the presence in the body of living tubercle bacilli. B C G was a living strain of fixed characteristics hereditarily attenuated after more than 230 subcultures on a glycerinated ox-bile medium. It was entirely free from pathogenic characteristics and the presence of bile rendered it more capable of absorption by the intestine of infants. Although when introduced into animals in massive doses it might give rise to tubercles, these underwent regressive changes and disappeared without leaving any trace. The organism, he believed, passed easily through the intestinal wall, and provided the animal was isolated for at least a month from contact with an infectious case an immunity was produced in cattle which lasted for about 18 months—i.e., so long as the bacilli remained in the lymphatic glands. Subjects already infected by virulent bacilli derived no benefit from the vaccine. Prof. Calmette denied that the B C G strain could ever become virulent in the way suggested by S. A. Petroff and others; he regarded such events as the result of accidental contamination. The method had been practised since 1924 in many countries of the world, and a fall in the tuberculosis mortality (and also in the general mortality) had been observed among vaccinated as compared with unvaccinated children. He claimed the method as suitable for universal application.

Qualified support was given by F. Neufeld (Berlin), while W. H. Park (New York) and Heynsieus van den Berg (Amsterdam), from a series of 365 children, recommended the method as free from danger. The

remainder of the ten official speakers had nothing but praise for the method, and advocated its more general acceptance. Some comment arose on the use of the general infantile mortality as a test of the efficacy of the vaccine; L. Bernard said it had been adopted to give greater accuracy, since it was impossible during life to diagnose tubercle with certitude among children. E. A. Watson (director of the Animals Diseases Research Institute, Ottawa) was the principal critic of the method; he had obtained, he said, 36 per cent. of mild tuberculous lesions by the injection of B C G, more or less severe in 2–7 per cent. A. Kirchner (Hamburg) supported Petroff's view. A. Fontes (Brazil) said he had observed no ill-results in a series of over 4000 cases. A. Greil (Innsbruck) condemned not only vaccination but the theoretical conception of immunity. No speaker touched on the recent catastrophe at Lübeck; as the causes of that unfortunate affair are still under consideration by the German health authorities all reference to it was excluded by common consent.

Thoracoplasty.

On the second day, P. Bull (Oslo) reviewed the work done in Norway upon thoracoplasty in the treatment of tuberculosis. He limited its use to chronic cases with unilateral disease in which an attempt to collapse the lung had been made without success. The operation, he said, should be undertaken only after a prolonged period of observation and if the other lung showed no signs. He preferred to perform the operation in two stages; there was no particular difference in results between local and general anæsthesia. Nearly half of the patients who could not be cured by other means were restored to full working capacity.

F. Sauerbruch (Berlin) spoke from an experience of 1200 cases with 40–50 per cent. of cures in strictly unilateral cases. He preferred to operate in one stage under local anæsthesia with ½ per cent. novocain. J. Gravesen (Vejlefjord) said 45 per cent. of over 200 cases had been able to return to work. His operation mortality was 7½ per cent.; he preferred general narcosis with morphine and ether, supplemented by suitable local anæsthetic. H. Morriston-Davies (Ruthin) believed that a large extent of rib resection was only desirable in old fibrous cases; in others it was unnecessary and harmful. After experience of both methods he had reverted without hesitation to the one-stage technique; he preferred a combination of light chloroform anæsthesia with 1 per cent. novocain. The general trend of other papers was favourable to the method and the discussion centred on points of technique. H. Vogel-Eysern (Davos) made a plea for greater application of functional tests for lung capacity before operation.

Teaching of Tuberculosis.

On the third day a discussion on the teaching of tuberculosis to medical students and practitioners was opened by W. His (Berlin), who based his remarks on replies to a questionaire sent out to many universities. While admitting that division into specialties contributed towards our knowledge of medicine, he had been impressed with the danger to science in general by undue specialisation. In no university in the world, however, was the teaching of tuberculosis entirely divorced from that of general clinical medicine. In most centres there were short courses, accompanied by visits to sanatoriums, where in some places students were guests for a fortnight or so. There was, he said, a dearth of post-graduate courses; some were given over a series of week-ends, so that neighbouring practitioners might attend. In Canada courses were provided by a prominent insurance company; some governments and national associations also granted travelling scholarships for this purpose.

Dr. W. B. Soper (New Haven) spoke of post-graduate teaching in America; in places where there was an enthusiast ready and able to give up his time and influence to teaching there existed a flourishing school of tuberculosis. In other places, he said, progress was less evident; a general stimulus was required. Dealing with undergraduate teaching Sir Robert Philip (Edinburgh) said it was not sufficient to train a student so that he was merely able to recognise the well-marked cases of the disease when it presented itself. Tuberculosis was a social malady of vast dimensions, and it was more important to impress the student with the way in which it entered intimately into the medical history of so many individuals. Pulmonary phthisis was not the only form which the disease took, and attention was too closely centred upon it. Undergraduates, he had found, welcomed the subject when it was put to them from a biological standpoint. E. Morelli (Rome) described the new Mussolini Institute for Tuberculosis and Respiratory Diseases which is being built in Rome as an international research centre with accommodation for over 1200 patients.

The conference closed with a meeting of the general assembly of the Union. Upon the proposal of C. Mainini (Buenos Aires) a commission was appointed with representatives from various countries, to consider the standardisation of nomenclature in tuberculosis. N. Heitmann (Government inspector of tuberculosis in Norway) gave a sketch of the development of tuberculosis work in Norway since the passage of the Act of 1900 which enforced notification and a system of treatment, and the part played in providing sanatoriums by the Norwegian Women's Public Health League started in 1896. Although since that date the fall of mortality in the towns amounted to nearly 50 per cent., the general death-rate for all forms of tuberculosis in Norway remains higher than that in Britain.

After the conference visits were paid to outlying sanatoriums, including that of Hagevik, near Bergen, admirable alike in situation and internal equipment.

The eighth meeting of the Union will be in 1932 in Holland, under the presidency of Prof. W. Nolen (The Hague).

SEAMEN'S HOSPITAL SOCIETY.—During the past year 6425 in-patients and 26,069 out-patients were treated at the various hospitals of the Seamen's Hospital Society, nearly half of them at the Dreadnought Hospital at Greenwich, 1538 at the Hospital for Tropical Diseases in Endsleigh-gardens, and 295 at the Queen Alexandra Memorial Hospital at Marseilles. The income was £93,578 and the expenditure £95,497. A new out-patient department and a complete theatre unit are needed at the Dreadnought Hospital at a cost of £35,000, and extensions and alterations at the Endsleigh-street Hospital are estimated at £20,000.

BRITISH DENTAL HOSPITAL.—The annual report states that the work at the treatment centres and clinics of the British Dental Hospital increases steadily. Larger buildings, better adapted and equipped, X ray apparatus, and research workers are needed, but cannot be supplied out of the fees charged to the patients. The centres at Camden-road, Lewisham, Tooting, and Hammersmith provide skilled dental treatment to persons not entitled to benefit under the National Insurance Acts, and another important branch of the work is the provision of dental facilities, in association with a number of metropolitan borough councils, for expectant and nursing mothers and young children. Last year 5273 children from London County Council schools were treated at the Lewisham centre, an increase of 458.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 6, 1930.

THE PHYSIOLOGY AND PATHOLOGY OF DIABETES MELLITUS.

In the Oliver-Sharpey Lectures, of which the second is published in our columns this week, Prof. J. J. R. MACLEOD has reviewed some of the experimental work designed to solve new problems which have arisen as a result of the discovery of insulin. The work was done mostly on depancreatised dogs which, though kept alive and well for a period by means of insulin, were found to die, as a rule, some eight months after the operation, with severe jaundice and fatty degeneration of the liver. The stools of the dogs always contained undigested muscle-fibres and a great excess of fat. On the assumption that the fatal issue might be due to lack of the external secretion of pancreas, Prof. MACLEOD tried giving the animals 2 oz. of raw pancreas a day. With this routine he was able to keep two dogs alive for four years, and but for an unfortunate accident it is probable they would have lived much longer. He suggests that the ability of dogs to survive may be determined by the presence of nodules of pancreatic tissue in the submucous layers of the duodenum. This hypothesis may explain the clinical observation that some patients with carcinoma of the head of the pancreas suffer much less from fatty diarrhœa than others on similar diets. Among other interesting observations was that on the effect of pregnancy. Dr. R. D. LAWRENCE has reported a case[1] which suggests that the fœtus may supply the pregnant woman with insulin during the last weeks of intra-uterine life. In Prof. MACLEOD'S experiments, however, the course of the pregnancy was quite normal, and the insulin requirements did not vary with the approach of full term. This observation renders improbable the hypothesis of fœtal supply, and another explanation must be sought for the change in the insulin requirements which has occasionally been reported during human pregnancy.

The symptoms following the withdrawal of insulin were carefully watched on several occasions, and one point which has an important bearing on clinical practice was noted. The fat animals developed on the fourth or fifth day a severe ketosis associated with vomiting, and died unless insulin was given; the thin dogs suffered much less from ketosis. By analogy, the diabetic patient who is fat is probably in much greater danger than a thin one if the insulin is omitted, and also if the dose is not increased promptly whenever the insulin requirements are greatly raised from any cause. The conditions which regulate the secretion of insulin from the β cells of the islands of Langerhans are fully discussed by Prof. MACLEOD. It has now been proved that stimulation of the right vagus nerve causes a decrease in the blood-sugar. This decrease is probably due to the secretion of insulin, but since we have no means of estimating the amount of insulin present in the blood, the relation cannot be accepted as certain. It is likely that the vagus centre is stimulated as the direct result of the increase in the blood-sugar. Prof. MACLEOD has tested the effect of some of the preparations which have been used as substitutes for insulin. Three substances, synthalin, myrtillin, and bile-salts have been tried, since experimental evidence that they have some effect on the blood-sugar is not lacking. Prof. MACLEOD concludes that synthalin does lower the blood-sugar of normal and diabetic persons, but is of no value in the treatment of coma. He finds that it can replace some 10 to 20 units of insulin, but that in view of its liability to cause toxic symptoms it is of little value in therapeutics. Myrtillin and bile-salts were found to have very little action on the blood-sugar, and none in depancreatised dogs; there seems, therefore, to be little justification for recommending them in the treatment of patients, and still less for prescribing for diabetics substances which have no action on the blood-sugar in any circumstances.

The study of Prof. MACLEOD'S two lectures shows that more is known about the physiology and pathology of diabetes mellitus than of any other disease. That this knowledge is, nevertheless, subject to important biochemical limitations is made clear from that section of Prof. H. S. RAPER'S address to the British Association for the Advancement of Science which deals with the hydrolysis and synthesis of glycogen in the human body (see p. 509). For example, it is not yet known how a synthetic product like glycogen is dealt with in the cell so as to protect it from the disruptive agencies which exist there. Arrangements for this purpose must be present since we know that substances may accumulate in cells which contain enzymes that hydrolyse them; for example, glycogen and amylase coexist in the liver cell. Again it has been proved that when glycogen breaks down in the liver it gives rise to glucose, and it is generally assumed that the synthesis of glycogen from glucose in the cell is brought about by the simple reversal of a hydrolysis which may be catalysed by enzymes under appropriate conditions. These conditions have, however, not yet been realised in vitro, and Prof. RAPER gives reasons for believing that the process is less simple. In his view it is probable that only the living cell can bring about the synthesis of glycogen. And it is at least possible that the substances from which glycogen is produced or bodies derived from them must first become bound up with, or at some stage form an integral part of, the living structure before they are converted into glycogen. Thus much remains to be learnt about even the main biochemical processes which control the metabolism of sugar in the animal body. But in spite of these gaps in our knowledge, the principles

[1] Quart. Jour. Med., 1929, xxii., 191.

of treatment of diabetes mellitus are beginning to stand out clearly, and it will be of interest to see how far these principles can be applied in the treatment of other diseases.

THE WINNIPEG MEETING.

FOR the third time in its life—it is now only two years short of a century—the British Medical Association has met in Canada, where it has been warmly received, the opening ceremony coinciding in fact with a rather embarrassing heat wave. The Toronto meeting of 1906 was held in a storm, during which one of the hospitals was struck by lightning. Of the Montreal meeting held nine years earlier, at which Lord LISTER laid the foundation-stone of the Jubilee Nurses' Home, we have no meteorological recollections. The third has been the largest, the number of registrations exceeding 2900, and the rendezvous all the more fitting inasmuch as the University of Manitoba and its College of Physicians and Surgeons, almost alone of the Canadian provinces, maintain full medical reciprocity with this country. The harassing restrictions of licensure were touched on in a moving part of Prof. HARVEY SMITH'S presidential address, which appeared in our columns last week. Our own General Medical Council has reiterated its desire for Imperial reciprocity of recognition in regard to medical qualifications, a reciprocity which would be facilitated if the Canadian provinces could come to some common agreement about their acceptance of the British Register. In addition to the presidential address, four important clinical addresses were given at Winnipeg. Sir LENTHAL CHEATLE dealt with the primary tumour in breast carcinoma on lines made familiar by his article in a recent issue of the *Cancer Review* (February, 1930). Sir WILLIAM WHEELER'S address on the significance of recoil following visceral decompression touched on the fringe of problems which concern not only surgeons but biochemists and physiologists. An abstract of this appears on page 541 of our present issue. Dr. W. E. DIXON'S address on drug addiction dealt in succession with the caffeine beverages, alcohol, heroin, cocaine, and the newest habit-forming drugs, and included an attempt to assess the world's need of narcotics in order to ensure that restriction shall inflict no hardship on the poor. The final address was on rest, work and play, in health and disease, by Sir FARQUHAR BUZZARD. His reminder that the recreation obtained from games depends mainly on the interest they evoke in the patient is timely; many practitioners nowadays forget that their own enthusiasm for athletic pursuits is not universally shared, and that some patients may prefer to earn by morning exercises the liberty to spend their days in more congenial occupations. On the last day of the meeting the Lister Oration was delivered by Lord MOYNIHAN, who commemorated JOSEPH LISTER in four aspects as benefactor, Quaker, surgeon, and man. The prevailing opinion, he said, was that LISTER was able to do what he did because of his supreme intellectual gifts. What was so often overlooked, he added, was LISTER'S possession of other qualities: his great heart, his humanity, his faith, his intellectual integrity. The clinical and scientific work of the meeting was organised in 14 sections, of which some account will be given in later issues. In the Section of Medicine the subjects of filtrable viruses, functional disorders of the colon, and acute poliomyelitis were covered in successive sessions; in the Section of Surgery recent advances in thoracic surgery, the uses of radium in surgery, and the surgery of the sympathetic nervous system. Special importance attached to the meeting of the Section of Tuberculosis, as it coincided with a visit of the British tuberculosis experts who had been making a prolonged tour of the United States and Canada.

LONDON RUBBISH.

LONDON contains an unparalleled conglomeration of human beings, whose rubbish presents a vast and complex problem about which everyone is becoming anxious. It is agreed that the metropolis is far behind the times in its arrangements for the collection of household refuse, and that the disposal works are out of date and inefficient. Matters were brought to a head by the issue last year of a highly condemnatory report[1] by a Government official in which every class of the community came in for blame. Householders were scolded because they do not burn their refuse, although their ability to do so has been impaired by installing gas fires in accordance with the injunction not to make black smoke; the contractor was scolded for collecting refuse more cheaply than the local sanitary authority is able to do; the authorities were scolded for not adopting uniform methods, although there is no agreement as to what method is the best. The Departmental Committee which was appointed to consider the Dawes report has now issued its recommendations,[2] of which the first and most important are:

(1) That it is no longer practicable for the 29 Metropolitan Sanitary Authorities within the highly developed area of the Administrative County of London separately to dispose of their refuse efficiently, economically and without causing a nuisance, and that the disposal of house, trade and street refuse in London should be centralised and placed under the control of one body.

(2) That the central body should also be responsible for the general coördination of the public cleansing service of London so as to secure, to the fullest possible extent, such uniformity of organisation and equipment as would facilitate the work in all its branches, and that it should therefore have jurisdiction over (*a*) types of refuse collection vehicles and refuse receptacles; (*b*) frequency of refuse collection; (*c*) inflow of refuse to discharge points; (*d*) avoidance of anomalies arising out of borough boundaries; (*e*) types of street cleansing vehicles and general equipment.

The formation and success of the Metropolitan Water Board has evidently led to the suggestion that there should be a Metropolitan Refuse

[1] See THE LANCET, 1929, i., 781.

[2] Ministry of Health. Report of the Departmental Committee on London Cleansing. Cmd. 3613. H.M. Stationery Office. Pp. 27. 6*d*.

Disposal Board; but there is a considerable body of informed opinion which finds little parallel between the problems presented by the supply of water and the collection and disposal of refuse, and which is distrustful of over-organisation. What are the leading facts? Admittedly there is a lack of uniformity in the methods of collecting the material, the arrangements for disposal of the refuse are in the hands of a few contractors among whom there is little or no effective competition, and the dumping of refuse—not only from London but from the great towns in the Outer Ring—in the country and semi-country round about the metropolis has caused much heart-burning. Dumps in the Essex marshes and elsewhere caught fire, emitted poignant smoke, served as a breeding place for flies and rats, and, owing to the continued extension of building, became an offence to an increasing number of persons. Administrative action was taken meanwhile in regard to a number of these dumps, the situation being improved by changed methods in depositing and covering the refuse. Miss SUSAN LAWRENCE, while describing the Essex dumps as a public scandal, pointed out that no Essex authority had yet made full use of its existing powers under the Public Health Act, and stated that the Ministry of Health would press for the discontinuance of insanitary dumps. Her remarks seemed to exclude the prospect of further legislation in the near future.

The Departmental Committee was not itself united on the constitution of the suggested central authority. Two members did not see their way to recommend the setting up of a new body with independent control, as this would involve interference with the powers of existing sanitary authorities. There is no reason to believe that most if not all of these authorities would not bring valuable contributions to a conference with the Ministry of Health on the collection and disposal of rubbish, or that they would not fall in with any suggestion made to them. The recent discussion at the Society of Medical Officers of Health made this pretty clear. No evidence was laid before the Committee that cleansing can be more efficiently done on a larger than on a smaller scale; no new methods were suggested that are not already well known to the cleansing departments. Dumping must be continued because there is ground to be levelled; salvage is of dubious value, although no objection can be raised to the use of suitable household refuse for brick-making provided the refuse is stored in an isolated situation; there is no consensus of opinion that electricity can be produced economically by burning refuse in destructors, even on a large scale. But now that public interest has been aroused, it may well be hoped that sufficient money will be spent on modern equipment for dust collection and for its hygienic disposal, use being made of the machinery of government available to-day.

ANNOTATIONS

VITAL STATISTICS FOR 1929.

The Registrar-General's Statistical Review for the year 1929, Part I. of which has just appeared,[1] confirms the provisional figures for the general birth-rate, death-rate, and infantile mortality issued earlier in the year.[2] The birth-rate of 16·3 per 1000 persons living at all ages was the lowest recorded since the establishment of civil registration in this country, the lowest rates previously being 16·6 for 1927 and 16·7 for 1928. The death-rate of 13·4 per 1000, against 11·7 for the previous year, was the highest since 1919, the increase being due almost entirely to the high mortality from respiratory and circulatory diseases and to the epidemic of influenza during the severe cold of February and March. The infantile mortality-rate of 74 per 1000 live births was 9 per 1000 above that of the previous year, the excess again due to the high mortality of the first quarter. With the exception of the pandemic of 1918–19 the epidemic of influenza was the most severe experienced in this country since the disease reappeared in 1890–91, the mortality being equal to 734 per million living against 196 in 1928. The mortality from respiratory diseases rose from 1507 in 1928 to 2104 per million, but the latter figure had been exceeded in 1920, 1922, and 1924. The mortality from circulatory diseases reached the record figure of 3030 per million, due largely to the deaths of elderly persons during the cold weather of the first quarter of the year. The death-rate from cancer was 1437 per million living against 1425 for the previous year, thus continuing the steady though slight increase over all recent years and being the highest crude rate recorded. The increase affected both sexes but was rather greater for females than for males. The mortality of women from puerperal sepsis and accidents of pregnancy and childbirth was 4·33 per 1000 live births, compared with 4·42 in the previous year. The improvement was not in respect of puerperal sepsis, which actually increased from 1·79 to 1·80, but in "other accidents of pregnancy and childbirth" which improved from 2·63 to 2·53. Although lower than that in 1928 the combined rate is still above the experience of the seven years 1921–27.

OPIUM AND SCOPOLAMINE BY THE MOUTH IN OBSTETRICS.

IN a long article, which is too largely composed of special pleading of a sentimental nature, H. Selheim discusses the pros and cons of the use of anæsthetics in midwifery.[1] With most of his opinions most English obstetricians are, no doubt, in agreement, for they express the general desire to reduce any intense pain in labour or so to control the natural process as to make it as little painful and as little dangerous as possible to the mother as well as the child. When it comes to practical recommendations for bringing about this desired end the novel suggestion offered by Selheim is that midwives should be allowed to administer omnopon and scopolamine by the mouth at the doctor's orders. He recommends a

[1] Med. Klinik, 1930, xxvi., 1103.

particular preparation for use in private practice consisting of omnopon 0·015 g., scopolamine hydrobrom. 0·0005 g., dissolved in brandy and syrup. The dose is to be given about three-quarters of an hour before the most painful stage of labour is anticipated. It may well be that some provision of this kind will be the essential outcome of the desire in this country to bring a measure of alleviation to the labour pains of the thousands of mothers who are confined outside institutions and under conditions which do not permit of ordinary anæsthetic administration.

CONGENITAL CLUB-FOOT.

In 1928 the British Orthopædic Association chose club-foot for the subject of the Robert Jones Gold Medal. The selection of this deformity for a prize essay was timely, for no comprehensive description of its pathology and its treatment seems to have been attempted in English since William Adams published his Jacksonian monograph on the same subject in 1873. Mr. E. P. Brockman, who has now published in the form of a monograph[1] the essay which earned him the medal, begins with an historical survey of the subject; this chapter provides a fair outline of the progress of orthopædic surgery, since the history of the treatment of club-foot up to the advent of Listerian surgery is really a reflection of the evolution of orthopædics. In discussing the nature of the deformity, Mr. Brockman describes the foot as being adducted, inverted, in equinus, and, lastly, plantar flexed or plantaris; this last term was originally introduced by F. R. Fisher, and is here revived with good effect. A suggestive analogy is drawn between club-foot and congenital dislocation of the hip. Mr. Brockman brings forward strong evidence, both clinical and pathological, for maintaining that club-foot is really a dislocation of the astragalo-scapho-calcanean joint, but that the astragalus is practically stationary, whereas the scaphoid has moved downwards, backwards, and inwards, carrying the forepart of the foot with it; the os calcis has also moved inwards. The effect of this migration is to approximate the scaphoid to the sustentaculum tali and thereby to diminish the natural capacity of the socket for the head of the astragalus, which consequently slips out uncovered and becomes palpable on the dorsum of the foot. From this view of the nature of the deformity the author passes on to a full discussion of its ætiology; the various theories are passed under review, a preference being expressed for the hypothesis that the deformity is due to an irregular development of the tissues of the foot and that the fault is of intrinsic origin and independent of extrafœtal influences. This view, it is maintained, best fits the pathological findings; the bones are least affected, for they are of normal shape, but the calcaneo-scaphoid ligaments may be deficient or absent and the muscles which control the socket for the head of the astragalus are contracted. The treatment of club-foot is well described and the difficulties associated with the unfolding of the deformity are thoroughly considered and discussed.

The ideal time to start treatment is about 10 days after birth; the necessary manipulations are set out in detail and the method of splinting favoured is that by means of strapping. The author deprecates the enlistment of the mother to participate in giving treatment, because of the force necessary in handling the foot, but some surgeons would not agree with this view. An intelligent mother is quite capable of carrying out the initial graduated manipulations, massage, and splintage. Tendon tenotomy, which at one time was so popular, is now used only when a resistant equinus remains, to cure which the tendo Achillis may be cut. But the plantar fascia often needs subcutaneous section as an aid to manipulation. In older children manipulation under anæsthesia with plaster-of-Paris fixation is the best procedure, but quite a number of patients are incompletely corrected by this means, and for them open operation is advocated after the age of 3 years. The type of operation described is in principle the one practised in recent years by orthopædic surgeons in this country; the author adds one or two modifications of his own. Ligaments and muscles only are cut, the bones are untouched. The plantar fascia and muscles are detached as far backwards and inwards as possible; the tibialis posticus is exposed and if very contracted is detached from the scaphoid and other tarsal bones. The scapho-calcanean joint is next identified and the ligaments on its inner and inferior aspect incised. By manipulating the foot the deformity should now be capable of correction and can be maintained in the proper position by plaster-of-Paris. In the after-care the teaching of corrective exercises to the child is important. But there remains the stubborn foot, familiar to all orthopædic surgeons of experience, for correction of which none of the procedures named is effective. For this intractable condition a bone operation is necessary, but we agree with Mr. Brockman that this should be delayed until near puberty. Each surgeon has his own method of attack on each case, for standardised plans are of little avail in the major degrees of deformity. Mr. Brockman favours Dunn's operation, which consists of an excision of the scaphoid and arthrodesis of the astragalo-calcanean, the calcaneo-cupoid, and the astragalo-cuneiform joints. Mr. Brockman has provided clear, well-reasoned teaching on one of the most baffling deformities which surgeons are called upon to treat.

[1] Congenital Club-Foot (talipes equinovarus). By E. P. Brockman, M.Chir., F.R.C.S., Orthopædic Surgeon, Westminster Hospital; Assistant Surgeon, the Royal National Orthopædic Hospital. Bristol: John Wright and Sons, Ltd. 1930. Pp. 110. 10*s.* 6*d.*

SMALL-POX AND VACCINATION.

The July *Bulletin* of the Office International d'Hygiène Publique in Paris includes a supplement[1] which will be found valuable by all those who are concerned with the control of small-pox and the promotion of vaccination. The supplement consists of an interim report of the Commission on small-pox and vaccination which was made to, and accepted by, the Permanent Committee of the International Health Office at its last session in May. The Commission dealt in this report with three questions: (1) nomenclature of the varieties of small-pox; (2) the occurrence and distribution of post-vaccinal encephalitis; and (3) the methods of vaccination and the dosage of vaccine which are officialy enjoined in different countries of the world. In so doing, the Commission has touched upon matters which are, at the present time, of special interest in England, and recent English experience has been freely drawn upon. The Commission has carried a stage further the decision of the International Conference on the Nomenclature of Causes of Death, 1929, that the generic term *variola* should be recognised as comprising at least two varieties, *variola major* and *variola*

[1] Obtainable from the Office International, 195, Boulevard St. Germain, Paris.

inor, or alastrim. The distinction, it is emphasised, one of epidemiological type rather than of mere nical characteristics of the individual case. Those hose function it is to collect data as to the occurrence severe complications and deaths, particularly nong the unvaccinated at the most susceptible ges, are usually in a position to satisfy themselves, the course of an epidemic, that the prevalent sease is of the "minor" variety, with few com- ications and practically no mortality, or that it is ie "major" or Eastern type of small-pox, and can pply administrative measures in the light of this nowledge, always with the confidence that the well accinated are protected against any variety of small- px. In respect of post-vaccinal encephalitis, the Com- ission has been fortunate in being able to collate ie experience of two countries in which this rare mplication has been most conspicuous—England id Holland. It has found that the same complica- on is liable to occur after the use of many different rains of lymph in other countries in Europe, and at it must be regarded as a definite risk associated ith vaccination, although it is one which is so rare hardly to require consideration unless the vaccina- on practice of the country entails the extensive imary vaccination of children at school ages, when is undoubtedly a factor which has to be reckoned ith. In this respect the Commission follows closely e findings of the report of Sir H. Rolleston's accination Committee in 1928. The last part of e Commission's report gives an instructive epitome the different ways in which vaccination is practised different countries, and presents a summary of plies to a detailed questionaire which the Office nternational d'Hygiène Publique addressed last ear to the several Governments which it represents. ost of the data given and the opinions expressed this report are new only in the sense that they have en brought together in a convenient form from many rts of the world, but they derive special value from ie broad basis of the inquiry, and from the authority ven to them by the representatives of the numerous ational public health services who took part in it.

THE COLOUR IN JAUNDICE.

THE usual complexion of the patient influences ery greatly the colour of his jaundice; those who e pale and fair tend to present a bright lemon- llow colour, but if the patient is naturally dark the olour is more of an orange tint or bronze. If ssociated cyanosis is present from other causes, a eculiar olive hue is produced; a similar green undice may occur without cyanosis, and it was ng thought that such cases were especially unpromis- g ones. An interesting analysis of jaundice by rof. T. Brugsch[1] is a welcome combination of inical observation and laboratory investigation. e suggests a division of cases of jaundice according their colour into four types, a "red," a "green," "flavin," and a "melasikterus," the last being iat browny tint which Brugsch compares in the ame "melasikterus" to the colour of treacle or olasses. According to him frank green jaundice only found with mechanically produced icterus— iat is, some obstruction is present leading to biliary asis, concentration of the bile, and absorption of is "thickened" bile into the blood; the tint is ie to discoloration of the skin with biliverdin. ed jaundice, on the other hand, occurs in all hepatotoxic" types, such as acute and subacute liver atrophy, and is due to the presence of bilirubin in the skin. The former colour is thus associated with biliary retention, the latter with failure of biliary secretion. When obstruction is present the bile retained in the biliary passages is for the most part oxidised to biliverdin, so that the more such oxidation takes place the greener becomes the jaundice; for this reason the direct reaction of the van den Bergh test in the blood-serum may gradually disappear and its place be taken by an indirect reaction, although the jaundice is undoubtedly obstructive in origin. In red jaundice no oxidation of bilirubin to biliverdin occurs, since the body tissues, apart from the biliary tract, do not appear to possess this property of oxidation; thus any appearance of biliverdin in tissues, skin, or urine is an indication of biliary stagnation. Flavin icterus Brugsch defines as that yellow jaundice which occurs with an indirect van den Bergh reaction in such conditions as hæmolytic jaundice, anæmia gravis, icterus neonatorum, and splenic anæmia. It is jaundice produced outside the liver and especially concerned with the reticulo-endothelial system, particularly the spleen. Clinically the colour is lighter than the red jaundice though of similar tint. Melasikterus is the type seen in conditions of cachexia and is rather a brown pigmentation than a true icterus. The differentiation of these clinical types of jaundice may be further assisted by a study of the iron in the skin. In the presence of the ferric ion an intradermal injection of potassium ferricyanide (freshly prepared 1 per cent. solution) produces a blue colour which is quite independent of the bile-pigments themselves. A positive iron reaction in the skin thus shows the presence therein of bivalent iron and together with a true bilirubin jaundice indicates an origin from hæmoglobin break-down. It is thus positive in red (hepatotoxic) jaundice and negative in green (obstructive) jaundice. It suggests a disorder of the liver-cells themselves.

It must be admitted that the exact mechanism of some types of jaundice is still far from clear, and in particular the rôle of the iron molecule is perhaps not as simple as might be believed from Prof. Brugsch's account. At the same time the broad divisions of colour described in his paper are interesting and serve to emphasise the importance of bedside observation.

LABORATORY OUTBREAKS OF PSITTACOSIS.

RECENT investigations of psittacosis in America have had dramatic sequelæ. In many of the laboratories where the disease has been studied cases of infection amongst research workers and attendants have occurred, some of which have proved fatal. Investigators at first assumed that psittacosis was an *aertrycke* or allied infection, and adopted what they considered suitable precautions, only to find that these were quite inadequate. But even those who came later on the scene, and were forewarned by the bitter experience of their predecessors, have not escaped, for one case of infection has occurred at the Rockefeller Institute despite most elaborate precautions. Perhaps none of these outbreaks has been quite so remarkable as that occurring in the Public Health Laboratories, Washington, which provided the material for a clinical survey by E. Petersen, O. B. Spalding, and O. Wildman.[1] This outbreak affected 11 persons; but its magnitude is not its most important feature, for of these 11 persons 9 had no access to the rooms in which the psittacosis investigation was being carried out. The laboratories concerned are housed in three

[1] Zur Analyse des Ikterus, Med. Klin., 1930, xxv., 413.

[1] Jour. Amer. Med. Assoc., 1930, xcv., 171.

buildings which communicate by tunnels and causeways, but the 11 cases of infection were confined to the personnel of the building in which the psittacosis investigations were being pursued and did not spread into the two other buildings. The infected birds were received on Jan. 16th, and of the three workers who handled them two fell ill on Jan. 25th and Feb. 6th respectively; one case proved fatal. The remaining nine cases appeared on Feb. 15th, 28th, March 10th, 11th, 12th, 13th (two cases) 14th, and 15th. It will be observed that the last seven cases occurred close together, suggesting, as G. W. McCoy points out[2] that they became infected about the same time from a common source. The nature of this common source of infection is obscure. Had any of the patients infected others in their homes one might have thought that the laboratory outbreak was due to spread from man to man; but no home infections occurred and, moreover, the history of this disease suggests that the human case is a negligible source of infection. Why infections should spread from parrot to man with such ease and from man to man with such difficulty remains a mystery, but an almost identical problem is presented by tularæmia and a most interesting line of research awaits the intrepid investigator of either of these infections. We have been fortunate in this country for, with precautions certainly no more elaborate than those adopted elsewhere, laboratory infections have not occurred apart from one relatively mild case.

The clinical part of Petersen, Spalding, and Wildman's communication covers ground now well known and brings no new facts to light. In his investigation of this disease in the Argentine last year E. Barros [3] made free use of X ray examination of the chest and spoke highly of its value. And if convalescent serum has not been used in this country in the treatment of psittacosis, it is for the good reason that experiment has shown it to have little or no protective value.[4] This finding is supported by the results now reported, for in our opinion the evidence provided contains no justification for the conclusion that the use of immune serum in daily doses was of "apparent benefit." A. P. Thomson obtained comparable results with serum from individuals recently inoculated with T.A.B. vaccine.

"SOCIAL ORTHOPÆDICS."

SINCE 1924 the *Cripples' Journal* and the *Cripple* have served a useful purpose in keeping the social side of work for physically disabled children before a wide public, and before these journals came to an end (at all events in their present form) their editor, Mr. Frederick Watson, called on the expert knowledge of his collaborators to produce a book [5] which he describes as "nothing more ambitious than an outline of some past and future problems of disablement in domestic life and industry." He does less than justice to an enthralling account of the fate of the cripple through the ages, from the Old Testament conception of deformity as a thing accurst, and the persecution of the Middle Ages, to the belated humanitarianism of the nineteenth century. In this historical survey he touches on the deformities once common among lace-making children in England, one of the evils of child labour which is still vigorously alive among the carpet-makers in Persia. A chapter on th influence of the war shows the evolution of th voluntary county and after-care clinics in Shropshir as a result of the stimulation of public sympath towards crippling; following this came the Red Cro campaign against rheumatism. In discussing th education and training of the cripple Mr. Watso stresses the importance to the State of a man who ca bear at least part of the burden of his maintenanc In this field America has far out-distanced us; a interesting chapter is devoted to the American schem under which every citizen has a right to vocation training for direct employment or rehabilitatio after accidental injury. In the final chapter outlined an abstract rather than a concrete constructiv policy, but at the present time it is perhaps impossib to do more. In the establishment of the new faith humanitarianism and in the extension of voluntar agencies for their relief and education cripples wil he believes, find salvation. The book is appropriatel dedicated to Sir Robert Jones.

THE TREATMENT OF TETANUS.

THE treatment of tetanus by massive doses antitoxin has a sound basis of experimental worl In 1917 Sherrington showed that antitoxin injecte in suitable amounts would protect monkeys in whic the disease had been produced artificially by th injection of toxin, but attempts to cure patien already showing signs of infection by this mea have proved disappointing. Dr. A. E. Paterson has just published the results of treatment of tetan in children by larger doses of antitoxin than ha previously been given. These results are so striking successful in comparison with those of previo observers that his method deserves wide publicit The outstanding feature of his practice is the amou of antitoxin given both at the beginning and throug out the illness. As a routine 100,000 (America units are given intravenously and 40,000 intr muscularly in the first place; the former dose repeated in 12 hours and then again at 24-hour intervals according to the clinical progress of th case, while the latter is repeated four-hourly, th amounts being gradually lessened and later given less frequent intervals. With this method of 2 consecutive patients 19 recovered, the dosage the successful cases ranging from 120,000 to 1,970,00 units. Difficulties connected with this treatment a that intravenous therapy in patients with tetanu especially in children, usually requires a gener anæsthetic, and the expense of large doses of ant toxin is considerable. Moreover, the injection a large amount of horse serum is not easy. Th last-named obstacle has happily been considerabl mitigated by the more concentrated antitoxin no on the market, the volume of 100,000 units now bein 60 to 70 c.cm. instead of 300 c.cm. as formerly. D Paterson quotes some cases in his series which a of especial interest. One patient with an incubatio period of six days progressed well for five days bu then died suddenly during a spasm. He had onl been given 240,000 units of antitoxin in this time and it is possible, in view of the results with later case that larger doses might have saved his life. Anothe case showed clearly that antitoxin should not b discontinued too soon, but should be carried on we into convalescence. This was a moderately seve infection which reacted well during the first few da of treatment. The intravenous injections wer

ıerefore, discontinued during the fourth day, but ı the fifth day the patient relapsed and the dose had be increased again. The patient then recovered. opley and Wilson [2] explain the discrepancy between ıerrington's results and those obtained in clinical ractice by the facts that toxin and not bacilli were jected by him and that the doses he used were ıormous considering the weight of the animals. he dosage used by Dr. Paterson is relatively only ightly less than that used by Sherrington. The ıthor is the first to admit that his series is too nall for any certain claims about the value of massive ıses of antitoxin to be made. They do, however, rongly indicate that the doses used hitherto have ·en much too small, and his results justify an ıtensive trial of larger doses particularly now that ıncentration of serum has overcome one of the chief ·chnical difficulties.

ICIDENCE OF CANCER IN MENTAL PATIENTS.

RELATIVE immunity to cancer in races and individuals is always of interest and the detailed investigaon of the phenomenon has been considered a fruitful ıth of research. The incidence of cancer on rtain races in Europe was studied in 1925 for the eague of Nations Subcommittee on cancer statistics, ıd Prof. Eugène Pittard, after undertaking this vestigation, had little doubt that the Nordic race as more subject to cancer than the other European ces and the Mediterranean race least so. A less mplex problem for detailed research was suggested the Commissioners for Lunacy in England, who their annual report for 1909 made the observation ıat the asylum patient appeared to be relatively ımune to cancer, as also to bronchitis, compared ith the general population. The Commissioners ointed out that the age incidence was the same in ıe two groups—that is to say, the normal population ıd the mentally affected, and that there had been ıe same apparent increase in the incidence of cancer both sections of the community in recent years. lthough the subject came under notice again in 923, nothing was done till 1929 when the newly eated infectious diseases subcommittee of the Royal edico-Psychological Association sent round a ıestionaire to 72 mental hospitals and then referred ıe replies to a professional statistician. The outcome[3] ıows, first, that both in the sane and the insane ıere has been a steady increase in the mortality om cancer recorded during the last 10 years from 919–29. Whether this is a real increase or merely ı apparent one due to more accurate statistics is impossible to say; since medical statistics were ıite inadequate in the past, an increase in cancer ıses with more carefully compiled figures is to be xpected. Secondly, the figures show that approxiately one-seventh of the deaths in England and Vales are attributable to cancer whereas only one-venty-sixth of the deaths in the mental hospitals are ıe to this disease—a much lower figure. Finally, for ıe period 1920–28 the death-rates from all causes the 72 mental hospitals are compared with those nong persons aged 15 years and upwards in the eneral population of England and Wales. The tal death-rates are 79 in the mental hospitals ıd 13 in the general population, while a comparison cancer death-rates show that there are 306 in the mental hospitals to 176 in the general population —i.e., less than twice as high. Before accepting these figures as representative it is necessary to ascertain how far the lower proportion of deaths from cancer in the mental hospitals is explainable by the very heavy death-rates in these institutions from other causes, such as general paralysis and tuberculosis. The "professional statistician" (unnamed) who analysed the figures for the Association draws attention to this need, and it is to be hoped that this important part of the study will receive prompt attention. Meanwhile an interesting addition to the report is the outcome of an investigation carried out by Dr. Arthur Pool at the County Mental Hospital, Rainhill. Dr. Pool undertook a study of the incidence of cancer in this institution over a period of 25 years, basing his figures upon an analysis of post-mortem records. He believes his results to confirm the low incidence of cancer in mental hospitals compared with the general community, but finds no increase in incidence with the passage of years; this last result, based as it is on actual port-mortem findings, is worthy of consideration. It is not, however, recorded what proportion of patients dying in the institution during the period covered by the inquiry were submitted to autopsy. If this proportion was not very high indeed some cases of cancer may have been missed. This is a less unwieldly field of research than is presented by the investigation of racial cancer; but more work, will be necessary to eliminate possible errors before definite conclusions can be drawn on the lines of detailed research planned out.

INTERNATIONAL LEAGUE AGAINST TRACHOMA.

IT is proposed that the next meeting of this League should be held in June, 1931, at Budapest. At the recent meeting of the League at Geneva, when Prof. de Grosz was elected President, the following were chosen as vice-presidents and members of the executive committee: Dr. Marquez (who was chairman of the International Ophthalmological Congress in Madrid), Mr. Szymansky (President of the Polish Upper House), Mr. MacCallan (representing the Ophthalmological Society of the United Kingdom), Mr. Morax (Paris), Mr. Angelucci (Naples), Mr. Birch-Hirschfeld (Königsberg). Other members of the executive committee are Mr. Brandes (Antwerp), Mr. Kadlicky (Prague), Mr. van der Hoeve (Leiden), Mr. de Lapersonne (Paris), Mr. Park Lewis (Buffalo, U.S.A.), and Mr. Miyashita (Tokyo).

THE ORAL ADMINISTRATION OF ŒSTRIN.

To the lay and also many medical minds it must have caused some astonishment that the International Congress for Sex Research, held in London during August, was concerned less with the sociological aspect than with the chemical side of sexual activity. The papers and discussions for the most part centred round the physical, chemical, and physiological properties of the internal secretions of the sex glands. It has long been known that the glands of internal secretion which play a part in sexual functions are not merely the gonads themselves but include more particularly the pituitary. In fact, recent work has been concentrated on the pituitary and the placenta to such an extent that œstrin and the testicular hormones have been temporarily eclipsed. Many of the communications at the Congress emphasised the importance of the pituitary, but the gonads were given due prominence. At Chicago, T. F. Gallagher,

F. C. Koch, and their colleagues have been working on the testicular hormone and described, among other developments, the method of testing the extract of testes upon comb growth in capons. The properties of the hormone were detailed. It seems clear that this work opened up an entirely new field in endocrine work. Amongst a number of interesting communications was one by Schoeller, Dohrn, and Hohlweg which dealt with the vexed question whether œstrin is active when given by the mouth. The original workers in America hold definitely that œstrin is inactive when given in this way, but in Europe it has been shown that oral administration can be effective under certain conditions. Allan, Dickens, and Dodds [1] found that some 25–30 times the subcutaneous dose was necessary to produce an effect on rats and that the distribution of the dose played a very important part in determining its activity by the oral as well as by the subcutaneous route. In Germany it has been claimed by many of the foremost workers that the amount required to produce œstrus when given by mouth is relatively little greater than when the subcutaneous route is employed; thus, Zondek maintains that the relationship is 5 : 1. Laqueur, on the other hand, maintains that 100 times the subcutaneous dose is necessary to produce signs of activity. Schoeller, Dohrn, and Hohlweg have now proved that another factor besides the distribution of the dose is significant—i.e., the purity of the material used by the different workers. Experiments with material of different degrees of purity showed the less pure material to have the stronger effect. Thus, with the pure crystallised follicular hormone (8 million units per gramme), it required 50 rat units to produce œstrus in 50 per cent. of the animals; with a preparation containing one million units per gramme 30 rat units were sufficient, and with one containing 0·2 million units per gramme 6 rat units had the desired effect. Moreover, it was found that with the aqueous alcoholic preparations the potency increased approximately in proportion to the amount of alcohol added. These important observations open afresh the question of giving hormones by the mouth, and it may be that a careful preparation of œstrin will be found effective when given orally.

[1] Jour. Physiol., 1930, lxviii., 348.

STATISTICS OF MEDICAL PROFESSION IN GERMANY.—A statistical record of the German Health Office states that the number of medical men has increased between 1887 and 1928 from 15,824 to 43,948. In 1887 7·2 medical men existed for each 10,000 of the population, whilst in 1928 33 were registered, that is, while there was formerly one medical man to 3000, now there is one to only 1400 inhabitants. From 1909, when qualifications were first granted to women, to 1913, the proportion of medical women to medical men was 1 : 26·5 against 1 : 5·4 in 1928. In 1928 the number of specialists was 8000, of whom 188 were medical women; 63 per cent. of the profession lived in towns and 37 per cent. in the country, the respective number for women being 79 and 21 per cent. respectively. While the number of medical men and women is continually on the increase, the number of midwives is diminishing. The number of nurses with general training is also increasing, the records for 1887 and 1928 being 14,000 and 102,000 respectively. As to unqualified persons, there were 1713 in 1887 against 12,000 in 1928, so that for each 10 qualified medical men and women 2·64 quacks are now engaged in practice.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE.

Proby. Surg. Lt. J. J. Dwyer to be Surg. Lt.

Surg. Lts. C. H. Birt to *Ormonde* and R. E. P. Cohe to *Glorious*.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Lt.-Comdr. G. A. Clark to *Victory*, for R.N. Hospita Haslar.

Surg. Lt. A. S. Bradlaw to be Surg. Lt.-Comdr.

Proby. Surg. Sub-Lts. J. C. Moor and J. E. Davenpor to be Surg. Sub-Lts.

ROYAL ARMY MEDICAL CORPS.

The undermentioned Majs. (temp. Lt.-Cols.) to be Lt. Cols.: E. Gibbon, vice Lt.-Col. T. S. Coates, promoted and R. W. D. Leslie, vice Lt.-Col. M. G. Winder, retd.

The undermentioned Majs. to be temp. Lt.-Cols.: C. Scaif and D. M. Corbett.

Capt. D. C. Bowie to be Maj. (prov.).

The undermentioned Lts. to be Capts. (prov.): T. E Moles and J. H. Anderson.

Lt.-Col. E. W. Siberry, having attained the age-limit o liability to recall, ceases to belong to the Res. of Off.

Lt.-Col. M. G. Winder retires on retd. pay.

Lt. E. H. Hall to be Capt. (prov.) and remains secd.

The undermentioned Lts. (on prob.) are secd. under th provisions of Art. 205, Royal Warrant for Pay and Pro motion, 1926: J. T. Robinson, T. M. Corcoran, and R. I Whittaker.

The undermentioned Lts. (on prob.) are confirmed i their rank: H. C. Benson, D. A'Brook, A. N. B. Odbert W. J. Officer, T. N. Fogarty, A. F. Kennedy, and J. C Macfarlane.

The undermentioned to be Lts. (on prob.): A. Guirdham J. T. Robinson, M. A. Rea, and T. M. Corcoran.

Lt. F. R. Gedye resigns his commn.

ARMY DENTAL CORPS.

The undermentioned Capts. to be Majs.: C. T. Hastin J. J. Boyle, and J. H. W. Fitzgerald.

Lt. (on prob.) A. F. D. Shapland is confirmed in hi rank.

Maj. T. K. Place is placed on the half-pay list on accoun of ill-health.

ARMY RESERVE OF OFFICERS.

Lt.-Col. A. D. O'Carroll to be Lt.-Col.

Capt. G. Moore, having attained the age-limit, retires an retains his rank with permission to wear the prescribe uniform.

T. A. Danby to be Lt.

TERRITORIAL ARMY.

Capt. T. S. Goodwin to be Maj.

INDIAN MEDICAL SERVICE.

Capts. R. C. Watts and Hari Das to be Majors.

The undermentioned Capts. (prov.) are confirmed in the rank: C. A. Bozman, M. L. Ahuja, and W. J. L. Neal.

Lt. T. C. Puri to be Capt. (prov.).

Lt. (on prob.) A. K. M. Khan to be Capt. (prov.) (on prob.

Lt. G. D. Mehta relinquishes his temp. commn.

INDIAN MEDICAL DEPARTMENT.

Senr. Asst. Surg. and Maj. A. E. Clarke retires.

ROYAL AIR FORCE.

E. W. B. Griffiths is granted a short service commissio as a Flying Officer for three years on the Active List.

M. Pearson is granted a temporary commission as Flying Officer.

Flight Lt. C. W. Coffey is transferred to the Reserv Class D. (ii.).

Flight Lt. P. E. Brown is promoted to the rank of Squadro Leader on promotion to Maj. in the Army Dental Corps.

MACKENZIE MEDAL FOR OPHTHALMOLOGY.—The custodians of the Glasgow Eye Infirmary hav awarded the William Mackenzie Medal for 1929 for origin contributions to ophthalmology to Prof. J. van der Hoev of Leiden, Holland. At 8.30 P.M. on Oct. 3rd he will giv an address at the Infirmary on Ophthalmology in it Relation to Other Branches of Medical Science.

CLINICAL INTERPRETATION OF AIDS TO DIAGNOSIS

Series of Special Articles, contributed by invitation.

LXXXIII.

THE CLINICAL SIGNIFICANCE OF SLIT-LAMP APPEARANCES.

PART III.*

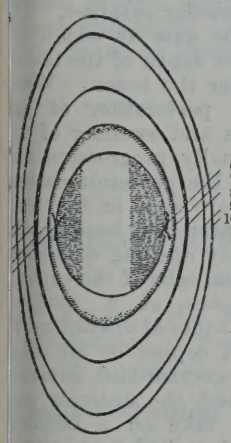
The Lens.

THE application of the slit-lamp to the crystalline ns has added to our knowledge of the anatomical ıd pathological appearances of this structure and ıe apparatus has become an essential for the iagnosis of various forms of cataract. Various ieans of examination are open to us:—

(*a*) Oblique illumination in focal light.
(*b*) Transillumination of anterior layers of lens substance y light reflected by deeper layers.
(*c*) Examination in zones of specular reflection, especially hen viewing the anterior and posterior surfaces of the ns or those of the adult nucleus.
(*d*) Most important is the use of the optical section which ds us in judging the relative position of opacities and the)proximate date of their appearance.

When the normal lens is examined it will at once e appreciated that it is not of uniform density ıroughout. It will also be observed that, in the lult lens at any rate, the changes in density occur)mewhat abruptly so that various well-defined layers are brought into prominence.

The diagram (Fig. 6), taken from Koby's book, shows the various surfaces of discontinuity where these abrupt changes take place.



IG. 6.—Diagram to show the surfaces of discontinuity of the lens. The numbers refer to the text. (Koby).

These so-called zones of discontinuity are named: (1) anterior band of the lens; (2) anterior band of discontinuity; (3) anterior band of the adult nucleus; (4) anterior peripheral band of the fœtal nucleus; (5) anterior central band of the fœtal nucleus; (6) posterior central band of the fœtal nucleus; (7) posterior peripheral band of the fœtal nucleus; (8) posterior band of the adult nucleus; (9) posterior band of disjunction; (10) posterior band of the lens. The clear interval between 5 and 6 is spoken of as the *central interval* of the fœtal nucleus, and here the density of the lens is most uniform. That portion the lens between the anterior and posterior bands of the etal nucleus represents the lens at birth. By about 25 years ıe adult nucleus is completed, and that part of the lens which outside these limits is called the cortex. The surfaces of ıe lens itself and those of the adult nucleus may be examined the zone of specular reflection so that now we no longer ıerely examine images formed at these surfaces (the images Purkinjé) but the surfaces themselves. It has long been nown that there is a system of sutures at the surface of the ns, and the slit-lamp has shown that this system is present the level of each surface of discontinuity. The sutures ıe simplest at the surfaces of the fœtal nucleus, the anterior eing in the form of a Y, whilst the posterior is in the form an inverted Y. These two figures are most useful in eciding the limits of the fœtal nucleus and hence in deciding ıe relative position of an opacity in the lens. The further moved we are from the surfaces of the nucleus the more mplicated the suturing becomes. The surfaces of the lult nucleus in later life show a relief like a plastic geographical map, and this is sometimes visible with the ordinary loupe.

The cortex of the lens increases with age as we would expect, knowing that the lens grows throughout life. The surface of the lens besides its suturing exhibits a peculiar shagreen; an example in ordinary life is seen at the surface of books bound in Morocco leather. This shagreen becomes modified and then disappears as a lens becomes progressively cataractous.

Certain congenital anomalies have been discovered in the lens and those already known have been examined and described in more detail. In connexion with remains of pupillary membrane fine filaments are sometimes adherent to the anterior surface of the lens, whilst in other cases the only remnant is a collection of fine brown stellate cells in the pupillary area. Almost constantly the remains of the hyaloid artery may be found down and in from the posterior pole of the lens, taking on the form of a small opaque disc to which is attached a short cork-screw like structure. Several cases of posterior lenticonus have been described although the condition does not appear to be strictly congenital as the fœtal nucleus in all cases has been found intact. The conical backward bulging causes a circular convex surface at the base of the cone to be presented forwards towards the light. Being a convex mirror it causes a circular reflex (the reflex of Vogt) which is also seen in connexion with the bulging backwards of Descemet's membrane in disciform keratitis. Posterior lenticonus is always associated with cataract in the posterior cortex. A common congenital opacity is seen in the form of tiny brilliant white dots at the level of the anterior Y of the fœtal nucleus. This suture may also show marked opacity, known heretofore as stellate cataract.

CATARACT.

Anterior capsular cataract is rare and is surrounded by a peculiar halo where no shagreen is seen. When anterior polar cataract is present its connexion with early life is shown by the fact that it may be reproduced at the surfaces of discontinuity in connexion with the fœtal and adult nuclei. Zonular cataract may occur as a congenital or an acquired condition and we may judge as to which it may be by its size and position. The opaque disc is seen to be formed of tiny white dots, a condition usual in all forms of nuclear cataract. Riders are commonly present, and Vogt has pointed out that they are often in the immediate neighbourhood of clear gaps in the periphery of the opacity.

Among the senile changes which occur in the lens the slit-lamp has been able to demonstrate that many changes, non-cataractous in nature, are commonly seen. These changes may or may not be associated with senile cataract.

As compared with that of the child the lens of the old person shows an increased internal dispersion of light. This is often associated with a deepening of the colour in the posterior part of the lens which is yellowish in appearance. This is partly due to the normal fluorescence of the lens whereby the light passing to the posterior part of the lens is deprived of some of the blue rays, and, after reflexion from the back of the lens, is further filtered before it reaches the observer; the result is that the rays from the red end of the spectrum predominate. Crystals with red or green reflex are sometimes seen. An almost constant feature is the formation of a relief at the surface of the adult nucleus and this may be examined best in the zone of specular reflexion. When performing an examination by retinoscopy one often finds a good deal of irregular refraction in the lenses of older patients. This is now demonstrated to be

* Parts I. and II. appeared in our issues of August 16th and 3rd respectively.

due to the formation of clefts filled with clear fluid occurring in the more superficial parts of the lens. They may arise in the site of a suture, when they are often regular in outline and may occur elsewhere among the fibres of the lens, where they are very irregular in outline. They make their appearance after 50 years of age, and are usually associated with lens opacities.

The slit-lamp has allowed us to observe a new phenomenon in the senile lens, which is usually associated with cataract. It is known as *lamellar separation* and is situated in the middle and deep layers of the cortex. It consists of a series of parallel lines running up and out from the lower nasal part of the lens. It is much more frequently seen in the anterior than in the posterior cortex.

From the clinical point of view the slit-lamp is so useful that it is possible to arrange the various types of presenile and senile cataract depending largely upon the layers of the lens in which the opacity occurs.

A very common type of presenile cataract seen in 25 per cent. of adults is *coronary cataract*. It interferes little, if at all, with vision since it is situated in the periphery of the lens and is only uncovered if the pupil be fully dilated. The opacities are thin so that they may be missed with the ophthalmoscope. They are club-shaped, nummular, or annular and appear blue or brown, depending upon the incidence of light. Another type of presenile opacity is *dilacerated cataract*. It is moss-like in appearance and appears, possibly congenitally, in the deepest part of the adult nucleus. *Cuneiform cataract* has been usually described in the past as peripheral striæ. These opacities occupy the deepest cortex, are whitish in colour, wedge-shaped, and occur both in front and behind the adult nucleus meeting by their base at the periphery of the lens. Dust-like cataract in concentric layers appears as very small opaque dots in the surface of the adult nucleus and the adjacent cortex. Posterior saucer-shaped cataract is usually described as posterior cortical opacities. It occurs in the most posterior layers of the cortex as a single layer. The opacities are dense and may be vacuolated and crystalline. Although it may not be very apparent with the ophthalmoscope, nevertheless it affects vision considerably and calls for early operation. Fortunately, the lens is considerably sclerosed so that extraction is not unduly difficult.

The opacities so far described which occur in the cortex are usually fairly gross in size contrasting with nuclear opacities which are usually minute.

Nuclear changes are seen in three forms: central hyper-refringence, black cataract, nuclear cataract proper. At the time when practically all we knew of the surfaces of the lens was their property of acting as mirrors producing images of Purkinjé, in certain cases it was noticed that two small subsidiary images appeared between those produced by the anterior and posterior surfaces of the lens. These were found to be produced by the anterior and posterior surface of the nucleus, and when it occurred it was noticed that the eye suffered from a marked degree of negative abberation. The condition was called false lenticonus. The slit-lamp has shown that there is an increase in the optical density of the nucleus of the lens. This increase begins in the anterior part of the fœtal nucleus, then the rest of the nucleus becomes involved and the central interval is filled up. The result is that the nucleus becomes homogeneous and of increased density throughout. In *black cataract* the increase in optical density of the fœtal nucleus is accompanied by a yellowish coloration especially well marked in the posterior part. This coloration may be red-brown or black. These changes in the nucleus are usually accompanied by senile changes in the cortex. In *nuclear cataract* proper there is a diffuse increase in optical density of the nucleus associated with actual opacity which begins in the deep layers of the fœtal nucleus, finally enveloping the adult nucleus. Here again there are usually senile changes generally of a cataractous nature in the cortex. *Injury* may cause dislocation of the lens, and when this takes place into the anterior chamber the slit-lamp allows a more detailed examination than is otherwise possible. Subluxation of the lens is practically always associated with prolapse of vitreous into the anterior chamber; in such a hernia of vitreous of greater or less size may be seen protruding through the pupil and covered in tiny brown particles of uveal pigment.

Peculiar changes are seen in the anterior capsule of the lens in glass-blowers and others who work with a furnace. The change consists in a peeling off of the most anterior layer of the capsule, known as the zonular lamella. The anatomical features of Vossius' ring, produced in the lens by a blow upon the eye, have been explained. The condition is now known as traumatic annular deposit. The ring consists of a circular deposit of brown amorphous granules on the capsule of the lens, actually an impression of the pupillary margin. Traumatic cataract appears in different forms depending upon whether the lens capsule has been opened or not. When the capsule is intact a characteristic opacity appears as a white rosette in the posterior cortex just under the cortex. This cataract is easily distinguished from other types of posterior conical opacity by its rosette shape and the fact that there is no lustre upon its surface. The prognosis of this condition is good. Occasionally a portion of the opacity persists, and if this occur in a young subject it may become buried in newly formed lens fibres the result being a traumatic lamellar cataract. The slit-lamp allows us to judge the date at which the accident occurred by the relative depth of the lesion the deeper the opacity the older the lesion. When traumatic cataract follows a perforation of the capsule a localised opacification and swelling of the lens fibres results. This is usually progressive and is associated with a rosette at the posterior cortex. The earliest signs of siderosis are seen in the lens a group of tiny brown dots appear first beneath the capsule just outside the pupillary opening consisting of iron impregnating the epithelial cells of the capsule itself. Later the lens becomes of a uniform brownish colour and the various zones of discontinuity disappear. When a particle of copper or an alloy of copper remains in the eye a greyish-blue cataract which is very thin is found, and the anterior and posterior surfaces of the lens take on a brilliant polychromatic lustre as if the lens had been plated with copper

Besides the changes in the anterior capsule mentioned previously other changes are produced in the lens in furnace workers. The disc line opacity at the posterior hole of the lens is well known. Some light has been thrown on the origin of this type of cataract by experimental work with infra-red rays focused upon the lens. In less than an hour cortical opacities may be produced. Recently considerable attention has been paid to certain changes that may take place in the superficial layer of the capsule in which a bluish lace-like membrane appears on the surface of the lens and peels off in small pieces. The importance of this process is that it is a cause of glaucoma (Glaucoma capsulo-cuticulare).

We are able to distinguish *complicated cataract* from other forms by certain marked appearances that have been demonstrated with the slit-lamp. The earliest change in the lens in the appearance of a polychromatic lustre at the posterior hole of the lens.

his appears before any opacity can be seen in ie lens and consequently is of prognostic import- ice. The opacity that subsequently appears involves veral layers of the posterior cortex and advances ially, in contrast with the posterior cortical opacity senile cataract.

A whole series of cataracts of peculiar appearance is been demonstrated by the slit-lamp; these parently arise in connexion with general diseases which there is apparently some deficiency in the ternal secretion of one of the glands. Roughly eaking these cases are similar in that the opacities e relatively small and appear in the superficial yers of the cortex just underneath the zone of junction. The diseases in which these opacities e found are myotonia atrophica, post-operative tany, traumatic myxœdema, mongolism and etinism.

Diabetes has been stated to be a frequent cause cataract, but it is only recently that a type of taract peculiar to diabetes has been described. the early stages the appearance is quite charac- ristic; a great number of tiny opacities in the most perficial layers of the cortex gradually fading away to the substance of the lens and the appearance small water clefts.

The Anterior Third of the Vitreous.

Only the anterior third of the vitreous can be ex- ined by the slit-lamp, and unless the pupil be dilated ly a very small portion in the axis of the eye. The rmal vitreous differs in its visibility in different rsons, but in a case in which it can be well seen the treous appears in a framework which is moderately minous and an optically empty fluid portion. This appearance is maintained in such a way, that although the structure oscillates in movements of the globe, yet when the eye comes to rest the original pattern reappears. In old age a characteristic appearance of the vitreous is sometimes seen. The strands of the framework become broken and small white irregularities appear on them. We have already noted the constant scattering of tiny particles of uveal pigment in the vitreous in contusion of the eye, and when the vitreous is prolapsed into the anterior chamber in dislocation of the lens or after discission of the posterior capsule. When there has been a perforating injury of the globe with prolapse of vitreous the framework of the vitreous is dragged towards the perforation in a characteristic manner and is a permanent change. In inflammation of the uveal tract we may see a complete destruction of the vitreous framework together with the appearance of opacities which are deposited on the fibres or float apart in the more fluid parts. The appearance in vitreous hæmorrhage is surprising. Unless the hæmorrhage is very gross and there are large clots in the vitreous visible by ordinary methods of examination we see fine white opacities deposited on the fibres of the framework and small reddish opacities, apparently blood corpuscles. It has commonly been stated that synchisis scintillans is due to cholesterin crystals in the vitreous. The appearance by the slit-lamp does not support this suggestion, since the opacities have not the form of crystals but of glistening white globules strung together like beads.

Ophthalmic Surgeon to the London Hospital; Surgeon, Royal London Ophthalmic Hospital.

SPECIAL ARTICLES

BRITISH MEDICAL ASSOCIATION.

ON August 28th, during the annual meeting of e Association at Winnipeg, Sir WILLIAM WHEELER livered a clinical address on the significance of

Recoil Following Visceral Decompression.

Excluding traumatic and acute inflammatory nditions, he said, a large number of the patients io sought advice suffered directly or indirectly m the effects of pressure or back pressure on an gan or system. An external stress acting slowly is followed by a mechanical adaptation; acting ickly, it might produce a strain sufficient to rupture irreparably disturb an organ or system. Unrelieved, led to secondary pathological phenomena and, if ddenly relieved, the recoil might cause cell rupture, scular derangement, or disturbances to the nervous echanism. The change produced in an organ by adually-increasing back pressure was probably imarily vascular. The direct pressure, combined th reflex vasoconstriction, closed some of the pillaries, thereby causing decreased blood-supply d function. On sudden removal of pressure e capillaries expanded and, with the removal of the soconstrictor reflex, the arterioles also dilated, oding the organ with blood. Cellular œdema, scular stagnation, and functional collapse supervened. eatment appeared to be governed by the universal principle that the greater the pressure the more gradual should be the relief. This principle applied to "medical," "anæsthetic," and "obstetric," as well as to "surgical" back pressure. Patients with back pressure in the heart were treated by those drugs which had the slowest and most prolonged action; if it were possible to reduce the blood pressure suddenly the cure would certainly be worse than the disease, for failure of heart and kidney would inevitably follow. Anæsthetists used spinal injection or chloroform cautiously if their patients had high blood pressure, for the rapid fall induced by these methods might produce an alarming reaction. The oculist dealt with glaucoma by gradual withdrawal of aqueous humour and avoided retinal detachment, vascular dilatation, and intra-ocular hæmorrhage by gradual decompression. If a hydramnios formed rapidly the circulation suffered and the patient complained of cyanosis of the lips, hands, and feet, and of indigestion and vomiting. If the membranes burst, however, the recoil caused syncope. The obstetrician laid special stress on making a very small or valvular opening in the membranes to ensure that the waters escaped slowly. Again, if the fluid from a hæmatocolpos were not drained slowly the patient might suffer extreme shock. In the realm of the obstetrician there was a striking example of accommodation to ever-increasing intra-abdominal pressure and to its release. M. Remy, however, had suggested that the evil results of release of pressure might be seen even in normal childbirth; death might occur without any lesion by a sort of

inhibition on the heart, as he put it, from the abdominal sympathetics.

THE KIDNEY AND LIVER.

Back pressure in the urinary tract was comparatively well understood. Cardiovascular disease kept company with prostatic enlargement in about 42 per cent. of cases, and improved as the renal function was restored. Gradual decompression was advisable in all cases, whether there was evidence of back pressure or not. Rapid emptying of a distended bladder by any means might be followed by acute œdema and congestion of the urinary tract, resulting in loss of function. These destructive changes contrasted vividly with the repair changes which followed decompression. A certain amount of regeneration of the epithelium of the tubules had been seen after incision or after the relief of hydronephrosis. The principal aim of decompression was to save any kidney tissue which had survived the destructive action of back pressure, for a very little renal tissue was enough for healthy life. The careful relief of decompression was accompanied by the disappearance of symptoms, but haphazard methods would not give uniformly satisfactory results. The van Zwalenburg method allowed the urine to trickle into a receptacle adjusted at the right level above the bed, and took two to eight days to empty the bladder. It was not safe to withdraw small amounts every few hours or to empty the bladder and partly refill it with some solution; both these methods produced sudden decompression.

Sudden relief of pressure on the liver was not so risky as sudden emptying of the bladder, since back pressure acted more slowly and less gravely on the cells of the liver. Nevertheless, sudden decompression sometimes caused cessation of hepatic function. Hepatic shock and insufficiency were not properly understood, but it was known that liver cells possessed a high degree of recuperative power and that measures for gradual vascular decompression—e.g., the Talma Morison operation—stimulated this recovery. Slow drainage of the gall-bladder or common duct in cases of biliary obstruction permitted this regeneration. Pressure causing loss of function was revealed by the appearance of white bile. When sudden operative decompression caused liver shock there was sometimes a free flow of bile, followed later by cessation and symptoms resembling those of uræmia.

ASCITES AND INTESTINAL OBSTRUCTION.

Even modern methods of withdrawing fluid from the abdomen were sometimes followed by cachexia, syncope, or hæmorrhage into the intestines and abdominal walls. Jaundice and grave nervous symptoms had been known to follow paracentesis in cases of cirrhosis. Since it was impossible to foresee these serious symptoms, the only safe course was to provide for very gradual decompression.

The gradual reduction of pressure in the distended large intestine, induced by preliminary drainage, probably accomplished far more than mere relief of toxæmia and restoration of the tone of the bowel and the size of its lumen. The intestine might show more repair after decompression than we yet knew of. In acute cases there was still a high mortality, and many suggestions had been put forward to account for this. Sir William Wheeler felt that, in his experience, acute cases did best when a slow, steady drain could be established through a small tube. Rapid drainage through a Paul's tube might be followed by deplorable results with the clinical picture of general shock. The results were alway good if the obstruction could be relieved simply—by dividing a band, for instance—and the intestina contents evacuated naturally, but a small enterostom tube acting as a safety valve gave equally good result and was essential in all but the earliest cases.

EMPYEMA.

Any change of pressure on one side of th mediastinum was accompanied by an almost equa change on the other side. Aspiration and slo decompression of empyemata had reduced mortalit from 40 or 60 per cent. to 5 or 10 per cent. Whe intrathoracic pressure was high the intercosta spaces bulged and the mediastinum, liver, and dia phragm were displaced. If the pressure wer suddenly released the result might be an acut pulmonary œdema or a to-and-fro flapping of th mediastinum which affected blood æration an circulation, producing a condition of shock whic often caused death. The line of safety was to aspirat or drain with a catheter before evacuating, whethe the pressure was high or only moderately raised, o whether the infection was streptococcal and diffus or pneumococcal and associated with adhesion Occasionally simple aspiration was followed by fata collapse. This was probably not due to vagal refle as had been suggested, but to flapping mediastinum.

CEREBRO-SPINAL DISORDERS.

Lumbar puncture might do harm or even kill th patient when performed during high intracrania tension. This was often due to wedging of th bulb in the foramen magnum, with resulting anæmi and paralysis of the vital centres. Lumbar punctur was especially dangerous in cases of hydrocephal due to tumour, and often caused giddiness, headach nausea, vomiting, and rigidity of the neck muscle Ill-effects were, however, very seldom produce if a small-bore needle were used and the fluid with drawn very gradually, the decrease of pressure bein controlled by a manometer. Spinal compressio might be aggravated by lumbar puncture and th signs and symptoms become worse; this effect migh be of diagnostic advantage. In some cases the roo pain became more severe and in others modera motor and sensory disturbances were followed b complete paralysis. Analogous changes might b seen in cases of intracranial growth. Th diagnostic aid, however, demanded a price which migh be severe unless the amount of fluid and the rate o withdrawal were carefully controlled. Lumbar punc ture was of decided value in the treatment of acut anterior poliomyelitis and posterior basic meningiti but a sharp distinction, Sir William Wheele concluded, must be drawn between diagnost puncture, which was safe, and medical decompressio which might be dangerous.

THE CANCER HOSPITAL, FULHAM.—Last year ther were 1162 new in-patients and 1557 new out-patient a substantial increase in each class. These larger numbe are to some extent accounted for by the work don with radium, cases being received for much short periods, and many more operations being performed, ar to the gradual education of the public in the importan of seeking expert advice in the early stages of diseas Although the hospital at present remains entirely fre "some means of encouraging, if not actually invitin patients to contribute as far as possible may," the repo says, "before long be devised." The hospital has bee using radium since 1903. The new buildings for the ele trical and radiotherapeutic department will cost £93,00 without counting equipment, instruments, appliances, & The appeal to the public has so far produced £17,500.

MEDICINE AND THE LAW.

Miners' Nystagmus and Compensation.

ANY general system of insurance against, or ompensation for, accident and ill-health demands good ith. In particular the provisions of the Workmen's ompensation Act which treat certain industrial seases as accidents of the employment must protect ie employer against liability where all-important formation has been suppressed or false information eliberately given. Thus Section 43 of the Act eclares that compensation shall not be payable "if is proved that the workman has at the time of ntering the employment wilfully and falsely presented himself in writing as not having previously ffered from the disease." The principle is simple ough but occasionally there is doubt whether the ate of the false representation synchronised with the ate of entering the employment. Where work is termittent, difficulty arises; the House of Lords d a difficult case of this nature to examine lately. he disease was miners' nystagmus. The first relevant ct in the workman's history was that in 1895, hen disabled by the disease, he finally settled his aim against his then employers for a lump sum yment. His subsequent work was done for a fferent firm of coalmasters by whom he was employed the following intervals. He first worked for them March, 1926, then went to Canada, but came back them in April, 1927. Up to this point he had made declaration. A few days later, however, he nt to another section of the colliery where, in his rk as a miner and brusher, he came under a different ushing contractor. He then made a written eclaration (found to have been wilfully and falsely ade) that he had at no time suffered from miners' ystagmus. Trade became slack and he was paid f in July and thereupon received unemployment surance benefit; he came back in August (under ie same contractor) and was paid off again September. On Nov. 7th (1927) he came back ice more and again made the false declaration. e remained at work till April, 1928; he made the eclaration a third time when he worked one shift a date in May. Otherwise he remained in receipt benefit till June 15th, from which date he worked ll August 26th. A few days later he was certified disabled by miners' nystagmus as from August 26th; has since remained totally incapacitated from that use. The Scottish tribunal of first instance warded him compensation, the arbitrator considering ie man to have been continuously employed from pril 27th, 1927, down to August 26th, 1928, except r the periods when unemployment was temporarily ie to bad trade. As no declaration had been ade on April 27th, the arbitrator saw no obstacle the award of compensation. Was this decision as the continuity of employment from April, 1927, wards a decision of fact which could not be disturbed n appeal? The Court of Session felt itself able to -open the matter and the House of Lords has nfirmed that Court's view. Under the Act the dustrial disease may be referred to any employment uring the previous 12 months; compensation is coverable from the latest employer, but the latest nployer may join up a former employer in whose eriod of employment the disease is proved to have een contracted; if the disease is of a gradual haracter, each of the successive employers must bear s share of liability in the proportion determined by ie arbitrator. In this sense employment for the previous 12 months is looked upon as one employment. This being so, the House of Lords decided that the employment which extended during the final 12 months before the certificate of disablement was the employment which began on Nov. 7th, 1927. The workman's entry into employment on that day synchronised with one of his false declarations; consequently, no compensation was payable.

The merely ethical view of the case (under which it would make little difference whether the false representation was made in November or a month earlier or later) is immaterial. The popular view may welcome adequate compensation and proper medical treatment for a miner suffering from nystagmus, but may grudge him the power to capitalise his total incapacity at frequent intervals at the expense of successive employers. Medical opinion may regret that significant information of the previous history of a specific industrial disease should be so easily hidden. If the recent case under discussion is not to be repeated, frequent medical examination of workmen and an elaborate system of filing their personal records might be of assistance. But employers deprecate the regimentation of industry, and workmen would have a right to resent the calendaring of personal details suggestive of the finger-print system of Scotland Yard.

Dangerous Drugs.

Geoffrey Bradford Wilmer, otherwise Melville, pleaded guilty at Maidenhead police-court on August 27th to six summonses under the Dangerous Drugs Consolidated Regulations charging him with unlawful possession of 300 tablets containing diamorphine chloride. He had been arrested at Northampton on a warrant issued last December, when a medical practitioner was convicted of offences under the Dangerous Drugs Acts. Wilmer, it was stated, had obtained the heroin from a duly qualified chemist in Maidenhead on the faith of prescriptions signed by Starkie, a London doctor whose name was removed from the Medical Register in 1922, a fact of which Wilmer was well aware. Wilmer made a long statement to the bench; subsequently Chief Inspector Prothero gave the court such information as the police had ascertained. Wilmer, he said, had represented himself as Major Wilmer and as Major Melville; he had also been known as Captain Nicholls and, at Melton Mowbray, as Captain Carter. Wilmer denied having used these names; he produced a bill for 170 guineas for medical treatment on which he was apparently described as Captain Arnold. The police-inspector stated that Wilmer claimed to have been an officer in the Essex Regiment, retired with the honorary rank of captain, and to have received shrapnel injuries in the war. He had not, in fact, been wounded in the war; he held no honorary rank as an officer, but was an imposter. The magistrates sentenced Wilmer to six months' imprisonment.

When the strict regulation of the possession and supply of drugs is taken into account it may seem surprising that it was possible for a man like the accused to be in possession of a considerable supply. In another case, disposed of at Wolverhampton some days ago, a medical practitioner who had become a drug addict was stated to have been supplied during a period of 11 months with 484½ gr. of cocaine, 825½ gr. of morphine, and 1912 drachms of liquid morphine. A doctor, by virtue of the general authorisation under the statute and statutory regulations, can, if he cares to abuse his authority, obtain supplies from different chemists by representing that the drugs are required for dispensing purposes. But a layman

like Wilmer has no such opportunity. The explanation in Wilmer's case is twofold. From statements made by Wilmer to the police, it appears that Dr. Starkie furnished him with a number of signed sheets of notepaper in blank; when Wilmer wanted a drug he filled up the sheet, which thus became a prescription. Wilmer also stated that, by an understanding with Dr. Starkie, he took whatever heroin he required out of drugs obtained on prescriptions in the name of a Mrs. Melville. A chemist, to whom the prescriptions were presented, was unaware that Dr. Starkie was an unregistered practitioner; he took the very proper precaution of communicating with him by letter and by telephone, but was reassured by the answers he received. The second explanation of Wilmer's success in obtaining supplies was that a chemist, again very properly, traced Dr. Starkie's name in the Medical Register, but in a copy for the year 1921 (before the name had been removed). Where chemists have taken such precautions it is certain that no magistrate or judge would encourage the taking of proceedings against them under the Dangerous Drugs Acts and Regulations; the police, therefore, are unlikely to initiate such proceedings. But the incident suggests the question whether it is part of a chemist's duty to possess an up-to-date copy of the Medical Register. It also suggests the further question whether the police, who apparently had had Wilmer's movements and purchases under observation for some time, do all that they can to warn chemists in any neighbourhood where a known drug addict is suspected of breaking the law. Though the facts in Wilmer's case do not justify the suggestion, there is sometimes a popular impression that the police are more anxious to accumulate evidence for a substantial conviction than to prevent the commission of crime. This impression will not be removed by the allegations in another case a few days ago where a man, described as a laundry canvasser, pleaded guilty to unauthorised possession of 56 g. of cocaine. The detective-inspector on that occasion had admittedly posed as a dentist; he had apparently said he was a sleeping partner in a firm of dentists, had produced £32 in notes, and announced that he could do with half a pound of the drug. Mr. Cairns, in passing sentence of three months' imprisonment, remarked that he would have imposed the maximum of 12 months if the circumstances had been different. Though full allowance must be made for the difficulties of suppressing the drug traffic, the magistrate may have shared the popular distaste for a situation created by a member of an English police-force turning himself into an *agent provocateur*. The restrictions on the supply and possession of dangerous drugs will not easily be enforced without the willing coöperation of medical practitioners or dental and veterinary surgeons. That coöperation will be more smoothly secured if their respective professions are not peopled with imaginary rascals created by the romantic inventiveness of the guardians of law and order.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.—In 1929 this hospital admitted a record number of in-patients—7247—whose average cost was £6 5*s.* 10*d.*, and there were 29,348 new out-patients. At £67,200 the income increased by £13,153, most of which was accounted for by larger legacies and an increase of over £3000 in receipts from the Hospital Saving Association. The expenditure was £60,319. The special clinics for rheumatism and asthma have proved most valuable; a new department devoted to guidance in matters of child welfare has also been started. Increasing demands upon the hospital have satisfied the board of management that the project of reconstruction cannot longer be delayed.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

OVERCROWDING OF THE MEDICAL PROFESSION IN FRANCE.

YOU have already noticed[1] the warning given s frankly and wittily by Prof. Carrière, of Lille. A report recently presented by Dr. Léon Bizard an Dr. Xavier Colaneri to the *Fédération des Groupe ments Médicaux* of the Paris area shows how startlingl rapid have been the changes which have produced crisis in the medical profession in France, owin to the great increase in the numbers of medica students and doctors. In 28 years the number o doctors has increased by 10,685, whereas the tot population of the country has increased by onl two millions in the same period. In the four-yea period 1925–28 there has been an increase o 3350 doctors, Paris and its suburbs alone havin been presented with more than a thousand new medica practitioners. Two main factors are held responsibl for this abundant invasion of the medical professio by new recruits. The first is the great attractio which the profession of medicine now has for women in 1929 as many as 2730 women registered as medica students, the corresponding number of male student being 10,650. The other factor is the great number o foreigners who join the medical profession in Franc Yet another factor is playing an important par though its influence is difficult to assess in figure It is the army of ancillary practitioners; nurses mal and nurses female, masseurs and masseuses, so disant auxiliaries who yesterday were the assistant of medical practitioners, and to-day are often the competitors.

Dr. Bizard and Dr. Colaneri propose severa remedies for a state of affairs which they conside deplorable. They recommend the addressing by competent authority of a circular to parents, scholar and teachers, stating the material and other obstacle at present obstructing the medical curriculum an profession. Doctors with university contracts woul do well to give addresses on this subject in the schoo of the country. An educational campaign woul also be useful in guiding medical students into by paths of the medical profession which are apt to b neglected, although profitable. Dentistry for doctor and the colonial medical profession are two suc by-paths, the following of which would do somethin to relieve the present congestion in the large towns i France. A measure which would be rapidly effectiv in reducing the number of entrants to the medica profession would be to put up a barrage at th examinations. It is pointed out that in the Facult of Law more than 30 per cent. of the examinee fail to satisfy their examiners, and the commo tendency for these 30 per cent. odd to find consolatio for their rejection in sweeping wholesale into th medical profession should be discouraged by raisin the standard of the medical examinations. If a medical students had to submit to a written anony mous examination, and were obliged to abandon thei medical studies after failing to pass their medica examinations on two or three occasions, the doubl purpose would be served of lessening the congestio and competition among doctors and of saving th public from an inferior class of practitioner. It i also hinted that candidates for a degree in medicin should undergo a medical examination, so that th

[1] THE LANCET, 1930, i., 1438.

uld-be practitioner too deaf to auscultate a patient uld be eliminated. It will be seen from the above narks that the dangers of a medical proletariat d other bogies in the medical profession in France e to a great extent those which face it in many other rts of the world.

THE PASSING OF THE OFFICIAL BROTHEL.

While one civilised nation after another has aban-ned the official regulation of prostitution, finding i so-called advantages a snare and a delusion, lance is still officially pledged to this system. It ay not be so for long. Indeed, there are already signs a revolt against it, in the provinces at any rate. Grenoble, for example, the municipal authorities lve just decided to abolish the regulation of prostitu-n, and to shut the *maisons de tolérance* as from n. 1st next. Behind this official decision is the rk of one man, Dr. Hermite, hospital surgeon d social worker, whose recent report to the municipal thorities showed in no uncertain terms what can be ne by a system of free consultations carefully ganised. During 1926 and 1927, and before his stem of free out-patient consultations was started, te antivenereal service registered 691 male and 481 fnale consultations. During 1928 and 1929, after fe out-patient consultations were started, the number c male consultations rose to 8449, and the number cfemale consultations to 4369.

HEALTH INSURANCE AND THE MEDICAL PROFESSION.

The medical profession in France has followed vth not a little anxiety the development of social i urance in general, and that of the law of April 30th, 30, in particular. The French medical profession is, ifact, only now beginning to face that problem which vs more or less solved in England before the war, d at a still earlier date in Germany. Late in July te Confederation of the Medical Syndicates held a reeting in Paris to discuss the attitude of the medical pofession to the new law. Dr. Dibos, who has seceeded Prof. Balthazard as President of the Con-fleration, was in the chair. Much dissatisfaction vs expressed by various speakers at the conditions vder which the medical profession would be obliged t work under the new law. It was, however, finally greed by a vote of 13,001 to 1668 to collaborate *citre d'essai* with the Government and all concerned i carrying out the provisions of the new law. Thus, vile pledging itself to act in a civic spirit as far as ossible, the medical profession reserves to itself the ht to reconsider the whole question should necessity se.

WIRELESS CAMPAIGN AGAINST VENEREAL DISEASE.

How times have changed since the use of the word philis was forbidden in French telegrams! That terprising broacasting station, Radio-Paris, has ently appointed a Social Hygiene Committee, sided over by Prof. Roger, and including such ll-known names as those of Profs. Balthazard, lon Bernard, Jean-Louis Faure, Gougerot, Marcel bbé, Roussy, Tanon, Weill-Hallé, Chailley-Bert, utier and others. Prof. Gougerot opened a series lectures on venereal disease, the titles of his narks being: "What is Syphilis?" and "The ngers of Undetected Syphilis." The reaction the French public to this daring innovation was aited with considerable interest. Three letters of postulation were addressed to Radio-Paris on this bject. But as hundreds of letters of approval were aultaneously received, it is safe to assume that this ucational scheme will be followed in its entirety.

THE BREEDING OF RAT-CATCHING CATS.

It is a curious fact that while for generations we have bred horses for speed and hens for laying, no one has systematically attempted to bring out and intensify by selective breeding the rat-catching qualities of cats. It is an extraordinary omission when one comes to think of it. A cat in whom the sight of a rat arouses no fiercer emotion than a mild and philosophical curiosity is almost unthinkable. Yet such has been the misconceived breeding of cats to fit them rather for the requirements of companionless elderly spinsters than for the destruction of rats, that a rat-indifferent or even a rat-fearing cat is now no uncommon sight. In view of these considerations it is reassuring to learn that the *Club pour les Chats Ratiers* of Havre has undertaken to organise a cat farm, the principal object of which is to breed genuine rat-catching cats. Dr. Loir, Medical Officer of Health for Havre, has already for four years been breeding cats for this purpose, and the port authorities and other interested bodies are contributing to the expenses of this undertaking, the results of which will be awaited with much interest by all concerned in the exterminination of rats.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

HEALTH PROGRESS IN DUBLIN.

FOR the past half dozen years or so the ordinary municipal government of Dublin has been in suspense, and its functions have been performed by three Commissioners, appointed by the Government, one of the three being a medical man. Recent legislation has, however, made drastic changes in the municipal government of the metropolitan area. The city of Dublin is now to be joined in a "greater Dublin" with the suburban townships of Rathmines and Pembroke, while the seaside townships are to be amalgamated into a coastal borough, with its centre at Dunlaoghaire (Kingstown). Elections for the councils of these two boroughs are to take place very soon and, consequent on the establishment of the council of the new Dublin, the rule of the City commissioners will cease. Their chairman, Mr. Seumas Murphy, has taken the occasion to give to the press a summary of the work accomplished by himself and his colleagues since they took office in 1924. As regards its effect on the public health there is a record of sound and enduring work. The water-supply of the city has been increased, and a greater pressure made available in order to safeguard the supply to the higher areas on the north side of the city. Not only have the road surfaces throughout the city been improved, but modern methods of street cleansing have been introduced. As regards housing, a large programme has been carried out by Dr. Dwyer, the medical commissioner. When the Commissioners took control the number of corporation houses was 2279, whereas the number at present is 5992. The annual rental has increased from some £43,000 to £160,000. Over 900 more houses are in course of construction, and schemes are on foot for an additional 777. The staff for dealing with the inspection of meat has been increased, and the inspection itself, both for home use and for export, is thorough. A new city laboratory has been constructed and thoroughly equipped. There has been a great development of infant welfare work, with a gratifying decrease in infant mortality. Children's clinics have been

established, as also antenatal clinics, dental clinics, and violet-ray clinics, and a diphtheria immunisation clinic. A system of medical inspection of school-children was established in 1928 and in two years some 25,000 children have been examined. The record is one of which the Commissioners have every reason to be proud. It has always been recognised that the rule by commissioners must be a temporary phase in the history of Dublin, but it has been a fortunate period for the citizens.

SWIFT'S ASYLUM.

Another step of progress has been made by the governors of St. Patrick's Hospital, commonly known as "Swift's Asylum," in the opening last week of a new wing by the Governor-General. The hospital was founded in 1745 under the will of Dean Swift, who left almost all his property for the purpose. As he put it in verse some five years earlier:—

> "He gave the little wealth he had
> To build a house for fools, or mad,
> And showed, by one satiric touch,
> No nation wanted it so much."
